My endeavor will now be to show *conclusively* that the epidemic in question was *not* the result *solely* of the contamination of the reservoir-water through the typhoid dejecta of the single patient who was confined in a house situated upon the bank of the mountain stream between the third and fourth reservoir, but was due to several concurrent causes, prime among which was the drinking of contaminated river-water.

So much has already been written upon the topography of Plymouth and its vicinity as to make the subject appear almost trite, but I shall be obliged to beg the reader to bear with me while I review as briefly as possible the locality and the existing sanitary condition.

The town of Plymouth is situated upon the right bank of the Susquehanna River, three miles below Wilkesbarre, and two miles below Pittston. The points of interest bearing directly upon this epidemic are, namely, the water-supply and the sanitary condition of the town. The water-supply, as obtained through the medium of the Plymouth Water Company, is from two sources. First, from four successive reservoirs, which are situated upon the mountain-side and fed by a mountain stream. The water thus obtained is distributed to the street mains from the lower of the four reservoirs, and delivered to the inhabitants by means of hydrants. Second, from the Susquehanna River. This source is only resorted to when water is not obtainable from the mountain.

In this case it is pumped directly into the street mains from a pumping station belonging to the Plymouth Water Company, situated upon the bank of the river at a point very closely corresponding to the centre of the town. There is still another system of waterworks located in the upper end of Plymouth, which are controlled by the Delaware and Hudson Canal Company, and serve the purpose of supplying their coal-breakers.

This system has two sources of supply. First, from a reservoir upon the mountain-side, which is filled by a mountain stream and springs. Second, by a reservoir filled by means of water pumped from the Susquehanna River ; main and branch pipes carrying the water from each reservoir to the "breakers." The latter source is

only resorted to when the former is insufficient to meet the demand. It is to be noticed that No. 1 reservoir, supplied by mountain, and No. 2 reservoir, supplied by water pumped from the river, communicate by means of the various pipe-lines. The pipes leading from No. 2 reservoir are supplied with valves, so that the supply can be effectually shut off from any "breaker" by simply closing the valve. River-water was pumped for the purpose of supplying these breakers during the entire winter, and the pumps were not abandoned until April 4th or 5th last. At the northern end of Plymouth is situated a hollow, called Whitewash Hollow, within which are located No. 2 and No. 3 "breakers." The drainage of this little valley is received by a creek, termed the Whitewash Hollow Creek, which, receiving the mine-wash from the above-named breakers, empties into the Susquehanna at the extreme north end of Plymouth.

A little below, and running in a northwesterly direction, is another hollow, termed "Polk Hollow." This contains No. 4 and No. 5 "breaker," and a creek, called Polk Hollow Creek, which receives the overflow from No. 1. reservoir of the Delaware and Hudson Canal Company. This creek receives the mine-wash from the latter breakers, and empties into the Susquehanna at a point some distance below the pumping station of the Plymouth Water Company.

I have given these details because they have an important bearing upon the subject we are about to discuss. The sanitary condition of the town is deplorable. It is filthy beyond description. There is indeed a system of drainage there, but the receptacle to a great extent is the town itself. It is a frequent sight to see a three or four inch drain-pipe emptying its contents into the street directly in front of a house which it is supposed to drain. This drain-water forms pools in the streets, and in some localities emits a stench which is next to unbearable. The locality is beyond dispute a malarial district, and the results of malarial infection are constantly present.

Before proceeding to the discussion of the various factors present in the production and continuance of this epidemic, it seems to me admissible to introduce a few aphorisms relating to the etiology of typhoid fever.

1. That there *is* a specific element necessary for the production of typhoid fever.

2. That the character of this specific poison is at present *unknown*.

3. That the specific element in the production of the disease can arise spontaneously has never been satisfactorily demonstrated.

4. That the specific element is contained in the excreta of an individual affected with the disease.

5. That the poison is not capable of reproducing the disease immediately upon its elimination.

6. That a period of decomposition is required outside the body before the specific poison assumes an *active* state.[1]

7. That the specific poison is not capable of reproducing the disease immediately upon its reception by the individual; but must pass through a period of incubation before the specific results are attained.

8. That there are (at least) two ways in which the poison may gain access to the system, viz., through the water that we drink and through the air[2] which we breathe.

The weight of authority is agreed upon these points, and I believe that my readers, with few exceptions, will concur with them.

After re-stating that the facts bearing upon the Plymouth epidemic, and the concomitant facts relating to the pollution of the water of the Susquehanna River at points above Plymouth, show *conclusively* that the drinking of this contaminated water was the causative agent productive of the first cases of the disease, it will be my endeavor to present these *facts* and make the deductions which they allow.

As has been many times stated, water was pumped from the Susquehanna River directly into the street mains, and used for drinking purposes by the inhabitants, from March 20th to March 26th inclusive. The first case of the disease appeared upon April 19th; new cases were constantly appearing until April 15th to April 18th, after which time there was a very large increase.

That the river-water was polluted with the sewage from the towns situated upon the banks of the river above Plymouth is a fact conceded by all; and that this water contained the specific element of the disease, is a fact denied by many, but conclusively demonstrated by the following statements: The physicians of Pittston, in answer to a circular, send me reports of 256 cases of typhoid fever which occurred between August 1, 1884, and April 1, 1885. We stated in our previous article that disinfection was improperly carried out at Pittston, the disinfectant used being the sulphate of iron, which has recently been shown by the New York Board of Health to be inefficient, and that typhoid stools treated by it are not rendered inocuous.

As previously stated, the sewage of Pittston empties directly into the Susquehanna River. The poison contained in the excrements from these patients, upon being thrown into the sewers, passed through its period of decomposition, and was continually discharged into the Susquehanna River in its *active* state until that river became frozen.

The physicians of Pittston, in reply to my question as to whether there had ever been an epidemic of the disease there, state that this condition existed last fall. This certainly accounts for the peculiar virulency of the river-water at the time when it was used for drinking purposes by the inhabitants of Plymouth.

There were a number of cases of typhoid fever in Wilkesbarre between the dates above mentioned, but, according to the statements of the physicians of the town, only a few of them were so situated that the excreta of the persons affected with the disease could gain direct access to the Susquehanna River.

Typhoid fever has been endemic in Plymouth for the past four or five years, and every time the river-water has been resorted to for drinking purposes there has been an increased prevalency of the disease. To demonstrate this, I will cite the following facts, for which I am indebted to my friend Dr. G. W. McKee, of that place. In 1882 river-water was pumped into the mains from October until January 1st, and it is a noteworthy fact that cases of the same type of fever which is now prevailing increased in number, and continued until some time after the pumping ceased. In 1883 river-water was pumped from the last of September to the 1st of February. During this time the same results were noticeable—the fever cases increased in number and virulency of type, followed by many deaths.

Again in 1884 the river-water was pumped from the latter part of July to the 24th of November. The same results were again noticeable. Finally, in the present year, from March 20th to March 26th inclusive, river-water was again resorted to, and following this pumping appeared the epidemic which is the subject of our discussion.

The people of Plymouth have an antipathy toward the using of river water for drinking purposes. This has been brought about by the results following the using of water obtained from that source in preceding years.

A short time since the citizens of Plymouth arose *en masse* and stated to the water company that under *no* circumstances would they hereafter accept of water obtained from the Susquehanna River, and that a non-compliance with this injunction would occasion such action as would result in the forfeiture of their charter.

I have now established four important facts.

[1] Loomis: Lectures on Fevers, p. 23.

[2] Murchison, p. 443; Liebermeister: Ziemssen's Cyclopædia, p. 56. Ibid. Quotes V. Giette Ziemssen's Cyclopædia, p. 56). Loomis: Lectures on Fevers, p. 24.

First.—That the river-water was contaminated by the specific element of typhoid fever in its *active* state.

Second.—That this contaminated water was supplied to the inhabitants of Plymouth at a time preceding the appearance of the epidemic.

Third.—That the use of river-water at other times has been followed by similar results.

Fourth.—That the common sentiment of the community condemns the water obtained from this source.

To assert in the face of these facts that the river-water was not even a factor in the production of the epidemic seems the height of presumption, to be accounted for only by the prejudice or self-interest of the investigators.

Such an assertion could not be made or maintained for a moment without the suppression or misstatement of important facts, or the deduction of wrong conclusions from facts correctly stated.

I now proceed to show in what particulars all this has been done by the "mountain-stream theorists."

I quote the following from the report upon the Plymouth epidemic by Drs. Shakespeare and French, of Philadelphia:

"March 20th of this year, at 5 o'clock, P.M., water from the Susquehanna was pumped directly into the main of the lower street, and this was continued without interruption until March 26th, at 5 P.M. During this period the river-water was unusually befouled by the sewage of Wilkesbarre, the water in the river being lower than for years, and its surface frozen tight.

"It was believed that none of the Susquehanna water reached the main which supplies Back Street on the hillside, for all connections between it and the main on the lower or Main Street had been cut off, except at the point, already mentioned, high up in the town, where the large pipe, descending from the reservoir, divides into the upper and lower mains. This belief was based upon the fact that when all the coal companies are drawing water the force of the engines of the water company is not sufficient to raise the water to the level of that branch. The water distributed from the Back Street or upper main was believed to be at that time exclusively mountain water. But we found, however, that water from the Susquehanna had not only reached the level above-named, but had actually been forced back into the reservoir, the level of its water having been raised three feet during two days of the pumping. This information is from the superintendent of the water company. He says that the small amount coming into the reservoir at this time from the mountain could not possibly account for the increase."

It will be seen from this that the distributing reservoir of the Plymouth Water Company was also contaminated with river-water below, as well as by the typhoid dejecta of the patient upon the bank of the mountain stream above.

The advocates of the "mountain-stream theory" further claim that there were several communities supplied exclusively with river-water, which communities obtained immunity from the disease.

Again quoting from the report of Drs. Shakespeare and French, they state:

"The population of Welsh Hill, be it noted, are not furnished with water by the water company of Plymouth, and therefore do not drink the 'mountain water' when they are at home. Their constant water supply, the year round, is principally Susquehanna water. There are, however, a great number of wells. The river-water is forced up by the powerful pumps of the Delaware and Hudson Coal Company, around whose 'breaker' this village or suburb is built.

"We found, first, that during the period of pumping, some of the Susquehanna water had reached the lower reservoir, as already stated, and had consequently not only reached all portions of the town supplied by the water company's pipes, but had also reached those people in the little fever-stricken dwelling located on the bank of the stream below the lower reservoir, who drew their water exclusively and directly from the brook. This fact of course complicated the question of the source of pollution of the drinking-water, although it still seemed probable that it was located along the mountain stream, for it was found that most of the sick had used water which was least contaminated by the Susquehanna. We found, second, that the people on Welsh Hill did not use any of the mountain water, but on the contrary got their hydrant-water directly from the Susquehanna at a point in the river *a half-mile nearer the sewers* of Wilkesbarre. In that part of Plymouth there is a population of eight hundred. Dr. Thomas Biddle, of this city, sends us the following facts: 'There is a total of nine ill of the fever. Five of these used water, while at work or at school, from the pipes of the water company in other parts of the town. Two of the remaining cases used well-water, and are recent cases, in all probability infected from those first ill.'

"This freedom from sickness at Welsh Hill clears up the doubt caused by the entrance of Susquehanna water into the reservoir."

Drs. Shakespeare and French have been misinformed regarding this matter, for the *facts* are simply these, that the community upon Welsh Hill are not, neither have they been, supplied with river-water at any time. There is not a hydrant upon Welsh Hill, and the only supply which these people receive from *any* system of waterworks whatever is through the medium of a pipe constantly furnishing a small stream of water, which runs into an old cask situated at some distance up Polk Hollow, from Polk Hollow Creek, which receives the overflow from No. 1. reservoir of the Delaware and Hudson Canal Company. This reservoir, as previously stated, is supplied by a mountain stream and springs.

Furthermore, the people in this community, according to their own statements, drink well-water exclusively. The erroneous statement of Drs. Shakespeare and French forms the corner-stone upon which they base their conclusions, and eliminates the possibility of infection from river-water.

The two other communities which it is claimed had immunity from the disease are, namely, Ridge Row and Broadway.

I quote from an article by Dr. L. H. Taylor, of Wilkesbarre, which was contained in the *Philadelphia Medical News* of June 20th:

"Is there anything further needed to convince the most sceptical that the Plymouth epidemic was not caused by using river-water? If so, here it is. In pursuing our investigation, we found at Ridge Row a community of twenty families living in ten double houses, and at Broadway a community of forty families in twenty double houses. These two places are in the upper end of Plymouth, and are entirely free from the fever. But all through the fall and winter, and even through the fatal month of March, they were supplied with water by the Delaware and Hudson Company, pumped directly from the deadly (?) Susquehanna, sixty feet from shore, and half a mile nearer to the Wilkesbarre sewers than the point at which the pipes of the Plymouth Water Company enter the river. It is proper to state that at Broadway there are two wells, and at Ridge Row one spring and one well, and no doubt many, especially at Ridge Row, used spring-water; but the majority of these sixty families used river-water exclusively, and continued to do so until April, and, as above stated, no case of the fever has appeared among them."

Dr. Taylor has also been misinformed, as the following statements will prove.

Ridge Row did *not* receive any river-water during the entire winter, as claimed by Dr. Taylor, nor has it received water from that source up to the present time. The hydrants at Ridge Row are supplied in the following manner: A pipe crosses over from No. 2 reservoir of the Delaware and Hudson Canal Company to supply

No. 5 breaker, situated in Polk Hollow. This pipe is tapped at Ridge Row, and the hydrants are attached to it; but during the entire winter, and up to the present time, the valve situated in the pipe leading from No. 2 reservoir to No. 5 breaker has been closed, thus effectually preventing any water entering that channel. The inhabitants of Ridge Row depended *solely* upon the well and spring water for their supply. Mr. O. M. Lance, superintendent of the Plymouth Water Company, stated to me that he was under the impression at one time that Ridge Row had received river-water, but that after discovering his mistake he had telegraphed to Drs. Shakespeare and French to the effect that they were not to use this information, as the statements which he had made to them relative to the matter were erroneous. I am also indebted to the foreman of the pumping station of the Delaware and Hudson Canal Company for the statement of these facts. Broadway, it is true, is supplied with river-water by means of three hydrants, but there are also two wells and two springs situated there, and the community, according to their own statements, use the well and spring water for drinking purposes. They are afraid of the river-water, past experience having taught them that it is contaminated. Only one case of typhoid fever has occurred in this community, this being a case of Dr. F. L. McKee's, the origin being *clearly* traceable to the drinking of contaminated *river-water*. Dr. Taylor further states that several persons came to Plymouth after the pumping of the river-water ceased, and consequently they could drink nothing but reservoir-water. Dr. Taylor loses sight of the *fact* that river-water was pumped into the lower or distributing reservoir as conceded by Drs. Shakespeare and French, in consequence of which fact persons arriving after the pumping ceased drank a mixture of river and mountain water.

Again quoting from Dr. Taylor, Dr. C. W. Spayd, a medical friend, in answer to certain inquiries, gives me the following:

"In the summer of 1884, typhoid fever broke out in Whitewash Hollow, a small valley that runs from No. 2 to No. 4 breaker and up to the Boston slope just below Larksville. In nearly every house from No. 2 to No. 4 breaker one or more members were down with it up to March of this year. The snow melted in that locality during the latter week of March very rapidly, filled the creek with running water, and, as the people were indifferent as to what was done with the excreta, it was carried down said stream into the river below Boston Hill, just above Plymouth, and in my opinion the fever sprung from the germs that were carried down into the river from Whitewash Hollow."

Now, at first blush, this might seem a point for consideration; but that it could have had no effect whatever in causing this epidemic may be shown from the following statements:

First. This stream joins the Susquehanna at the upper end of Plymouth, and anyone taking the trouble to examine it will find that it remains a distinct stream, flowing close to the right bank of the river for a long distance, and does not readily mingle with the general current. The Plymouth Water Company, however, took their supply two hundred and fifty feet from shore.

Second.—There is but very little sewage carried by this stream at any time, as but few houses are situated directly upon its banks.

Third.—Whatever this stream might contain, it did not, by any possible chance, empty any surface-water into the Susquehanna in March previous to the 26th, much less previous to the 20th, for the temperature during the greater part of March was far below the freezing-point, thus preventing any thaw of any consequence at this time. As is well known, March was the coldest month of the past winter. On March 20th, the maximum temperature was 20° F.; March 21st, 20.1° F.; March 22d, 20.1° F.; March 23d, 23.2° F.; March 24th, 35.6° F.; March 25th, 34.8° F.; March 26th, 46.5° F. So it will be seen that there was no day previous to March 26th that it would be possible for any considerable thaw to take place.

I grant to Dr. Taylor that the pollution at this point occurred too late to enter as a factor into the production of this epidemic, but suppose that we apply the same test to the mass of typhoid dejecta situated upon the bank of the mountain stream. The excreta from the patienta ffected with the disease at this point were thrown upon the frozen ground from January until some time in March.

The mean temperature for the month of January was 24.8° F.; February, 17.8° F.; March, 25.6° F. The daily mean temperature from March 20th to March 26th inclusive was respectively 9.7° F., 11.2° F., 12.9° F., 16.4° F., 27.5° F., 27° F., 38° F. It will be seen, as stated by Dr. Taylor, that any considerable thaw was impossible previous to March 26th. He nevertheless asks us to believe that the typhoid dejecta situated upon the mountain-top (where the temperature remained considerably lower than at Wilkesbarre, at which place this record was taken) passed through the period of decomposition necessary before the assumption of its active state, was discharged into the mountain stream, flowed on through three successive reservoirs, and was received by the inhabitants of Plymouth, they passing through the period of incubation necessary before the appearance of the epidemic upon April 9th.

This is almost *too* much to accept in the face of the facts cited above.

The average period of incubation, as ascertained by Lothholz, Gerhardt, Haegler, and Liebermeister, is twenty-one days. In accordance with this period the specific results following the pollution of the river-water by the typhoid dejecta situated upon the bank of the mountain stream could not have been attained (allowing some time for the period of decomposition) before April 15th to April 18th. Now, what occurred at this time? A large increase in the number of cases, pointing, we think, to a double contamination.

Dr. Taylor furthermore states that some persons who came to Plymouth upon April 1st, and drank the water for the first time upon that date, were taken sick as early as April 15th, showing a period of incubation of about two weeks. I quote from Liebermeister (in Ziemssen's Cyclopædia), to the effect that patients coming from a distance into a locality infested by typhoid fever succumb earlier to the disease and pass through a shorter period of incubation than those residing in the infected district. It must also be remembered that these patients drank of the reservoir-water at the time when it was doubly contaminated, thus receiving the poison in a more concentrated form. The natural assumption is that the period of incubation would be somewhat shorter in these cases.

We conclude,

First.—That the production of the epidemic of typhoid fever at Plymouth, Penn., was not *solely* dependent upon the contamination of the reservoir-water by the dejecta of the one patient affected with the disease, but *was* the result of several concurrent causes, *prime* among which was the drinking of contaminated river-water; and that this was followed by contamination of the pipes by the river-water which they had previously contained, contamination of the distributing reservoir by the river-water that had been forced into it below, and subsequently, pollution above by the typhoid dejecta of the patient situated upon the bank of the mountain stream.

Second.—That the continuance of the epidemic was influenced by the existing sanitary condition of the town and the establishment of independent foci of infection, resulting from the careless disposition of the evacuations of those affected with the disease, and the negligence exhibited in the carrying out of the measures for disinfection, as prescribed by the physicians.

Third.—That as a result of this careless disposition

and non-disinfection of the typhoid excreta, the air became contaminated, thus adding another mode of infection.

If these conclusions are correct, it would be a serious wrong to permit the people of Plymouth to rest in the conviction that all medical authority favors their free use of the water obtained from the Susquehanna River, however much such conviction might benefit the officers and stockholders of the Plymouth Water Company.

It affords me pleasure to acknowledge the courtesy which I have received at the hands of the physicians and citizens of Plymouth, and my indebtedness to all those who have so kindly answered my inquiries and aided me in the gathering of the facts contained in the above article. I also desire especially to express my thanks to Rev. Dr. Hodge, of Wilkesbarre, who furnished me with such a reliable record of the thermometric range.

Clinical Department.

RHUS TOXICODENDRON IN THE TREATMENT OF ENURESIS.

Dr. George W. Willeford, of Glendale, Ind., writes: "On reading the excellent article upon enuresis in The Record of June 27th, by Alexander W. Stein, M.D., I was very much surprised to find that in enumerating the drugs employed in the treatment, he failed to mention the most efficient remedy which I have yet employed. In the limited experience had in the treatment of enuresis in the past two or three years, as it has occurred in a country practice, I have found the fluid extract of rhus aromatica to give permanent relief in seventy-five per cent. of the cases treated, and to greatly benefit the remaining twenty-five per cent. As the article is comparatively a 'new remedy,' I have no doubt that there are many excellent practitioners who have never given it a trial. To those who are sorely puzzled to know what remedy to 'try next' in obstinate cases of enuresis, I will say, try a good preparation of the fluid extract of rhus aromatica, and you will find in it a pleasant and generally an efficient remedy."

HEMIPLEGIA AND ABORTIONS.

Dr. W. F. Lynch, of Volcano, Cal., writes: "Mrs. L——, aged twenty-nine, a lady of what may be termed a nervous temperament, with good family history, as far as learned, mother of four children, the youngest being at the time of which I write, four years of age, was stricken on July 11, 1884, with hemiplegia involving the right side. She was found at 6 A.M. on the floor unable to rise. Assistance was called and patient put into bed. I saw her an hour later. She was utterly unable to move arm or leg; the right facial muscles were also involved to a considerable extent, the tongue protruded to the right, could not close upper eyelid firmly and the face on this side was devoid of expression; there also existed some difficulty in deglutition. The sense to touch was considerably diminished. She could speak with difficulty and not very intelligently. Two days later she could raise herself somewhat in bed and could move her arm and leg some, but she had no power to move her fingers and toes. For a few days there was a little tendency to retention of urine, but this passed soon. She improved rapidly in strength and power to move her limbs, with, at the same time, an improvement in mind, though an aphasic condition still continued, until at the end of two weeks she could walk about the house by pushing a chair in front of her for support, and with the use of the battery, combined with the administration of tonic remedies and good diet, was in a fair way toward great improvement. About ten days after the attack of hemiplegia came on, the patient informed me she had been flowing for a week or ten days slightly, but this had increased considerably and I was shown an embryo which had been discharged a day or two before. Ergot in moderate doses was ordered, but this seemingly was not of much utility, and gallic acid was then ordered and the hemorrhage was controlled a day or two later.

"Up to August 9th patient continued gradually to improve and was able to walk out to some extent, though the leg dragged a good deal and she had not regained the use of the arm. The mind seemed brighter, yet her speech remained considerably impaired, thick and heavy, and the memory was not very clear.

"On September 3d the patient had another miscarriage from which nothing serious resulted. She continued after this to gain little from time to time, in strength and in the use of the lower limb—her arm did not improve.

"On November 14th at 4 A.M., I was summoned in haste, and found that the patient had been flooding profusely, the bed-clothing about her being thoroughly saturated with blood and the woman in a fainting condition; extreme pallor of face, and pulse very small and soft. The hemorrhage had ceased to a great extent before my arrival. Ten days before this, she had walked quite a distance to consult a female abortionist. The exertion of walking, or the abortionist, either one or both, had proved too much for her, for the next morning hemorrhage commenced, and a week later a fœtus of about two months' development was expelled, but not the placenta. After fœtus came away, hemorrhage ceased for two or three days, but returned with a rush on the date mentioned. A slight flowing continued for four or five days, at which time I removed, without much difficulty, the placental remains. After this the patient became better and was up and able to walk about as before, and I did not see her again until December 16th, when I was again called in. She had been taken about the 5th, during my absence from town, with an attack of fainting, followed by great nervousness, suffering from pain in the cardiac region, cardiac palpitations, and since had been confined to her bed. I found her in a very despondent condition, unable to control her emotions, subject to excessive fits of weeping and inordinate laughter, memory seemed failing, and there was pain felt in the left parietal region, quite severe at times. On several occasions passed urine in bed involuntarily, and on the next day, the 17th, passed fæces in bed without her knowledge. On this date Dr. T. H. Mayon, of Amador City, saw the case in consultation, and noted a tender spot in the spine about the fourth or fifth dorsal vertebra. The result of the consultation was, that the case was pronounced hopeless as to cure, and an early and fatal result anticipated.

"A few days before the consultation, uterine hemorrhage again commenced slightly, but no thought was given to it as the period for menstruation was due. The hemorrhage, however, continued up to January 28, 1885, and at times was a little foul. I determined to introduce a sponge tent and learn by digital exploration, if possible, the cause of the continued flowing. I did so, and the following day, the tent having been within the cervix uteri about twenty hours, thoroughly curetted the uterine walls and brought away quite a quantity of small granular masses. The hemorrhage ceased in a day or two, and from that time there was no more involuntary micturition.

"The patient has not been able to walk, nor has she been as well since the fainting fits occurring in December, which were probably further hemiplegic attacks. At times since January she seemed to grow a little stronger and felt better, yet during the last two or three months she has failed very greatly. She cannot stand without strong support. The flexors of the arm are in a state of constant contracture, and at times she suffers very severely from painful tonic spasms of muscles of the arm. The muscles of the leg are also affected in like manner, though not so marked. Both limbs have wasted away a

great deal. The right facial muscles are still affected, though she has much greater power over these than formerly. Her mind is very weak, and her speech very heavy and almost unintelligible. At times she has manifested suicidal tendency, and she is greatly troubled from insomnia. The treatment has been essentially of a tonic nature, good nourishing diet, and as remedies. iron, quinia, strychnia, and nux vomica mainly, the occasional use of the battery until the last two months, and regular use of friction to the affected side.

"One point not mentioned which perhaps should have been referred to at the commencement of this article is this: the patient has been a victim to twelve miscarriages in three years, three occurring from the time of the first hemiplegic stroke, from July 11th to November 14th! Is there any wonder that nature, so greatly imposed upon, should at last enter a protest against such maltreatment, for all these abortions were induced either by the patient herself or by a female abortionist?

"Another interesting point, was the relief of the involuntary micturition, following the curetting of the uterus for hemorrhage; this symptom continuing from about December 5th, the time the hemorrhage commenced, up to January 29th, almost to the very hour of the operation of curetting the uterus."

Progress of Medical Science.

A Case of Cholecystotomy.—Dr. Parkes, of Chicago, in the July number of *The American Journal of the Medical Sciences*, reports an interesting case of cholecystotomy, which operation appears to be becoming a rather common one in these days of fearless abdominal surgery. Of the cases submitted to operations, by far the larger portion has been of cholecystotomy, by means of which a distended gall-bladder has been positively relieved, and in most of them the cause of obstruction, retained gall-stones, removed. In a few no gall-stones were found, while in others the cause of the obstruction could not be remedied. In Dr. Parkes' case the gall-stones were not lodged in the gall-bladder, and it is highly probable that they were retained in some of the dilated hepatic ducts, and were washed into the cyst by the flow of biliary fluid which came on immediately after the formation of the fistula. He is inclined to believe that they had but little to do with preventing the flow of bile into the intestine, at least the patulency of the passages was not restored by their removal. The remarkable and profuse flow of muco-biliary fluid, coming through the sinus established, argues very strongly in favor of the operation which contemplates the formation of a fistula in the gall-bladder in distention thereof by confined secretions. Certainly no tube of the dimensions of the ductus communis choledochus could have given a free exit to the secretions; at least the accompanying back pressure on the walls of the cyst would have greatly endangered, if not certainly destroyed, the adhesions in any recent wound thereof, even when protected by the continued suture. Most of the cases of reported cholecystotomy tell of the presence of a freer flow through the fistula, so that it is a condition to be expected, and makes immediate closure of the bladder-wound without drainage a dangerous proceeding to adopt, even if we can be positively sure of a clear common duct. Dr. Parkes, in conclusion, advises, from his experience in this case, the general practice of sounding the common duct through the external opening. He is quite sure that such procedure can be safely carried out, and equally certain that its adoption in his case resulted in relief that did not follow the removal of the calculi alone.

The Pneumonia-coccus of Friedlander.—Dr. Sternberg calls attention to the so-called pneumonia-coccus of Friedlander, which he claims is, in fact, identical, specifically, with a micrococcus which he previously described, and which is found in normal human saliva, and with that found by Pasteur in the blood of rabbits which had been injected with the saliva of a child which died of hydrophobia in one of the Paris hospitals. This micrococcus he names *Micrococcus-Pasteuri*. The capsule, or mucous envelope, which sometimes surrounds this micrococcus, described by Friedlander in 1883, and photographed by Sternberg two years previously, cannot be accepted as a distinguishing character of this species, inasmuch as it is not constantly present, and the circumstances upon which its development depends have not been accurately determined. It is established that this is a pathogenic organism, as far as certain lower animals are concerned, and that its pathogenic power varies under different circumstances. It seems extremely probable that this micrococcus is concerned in the etiology of croupous pneumonia, and that the infectious nature of this disease is due to its presence in the fibrinous exudate into the pulmonary alveoli. But this cannot be considered as definitely established by the experiments which have thus far been made upon lower animals. The constant presence of this micrococcus in the buccal secretions of healthy persons indicates that some other factor is required for the development of an attack of pneumonia; and it seems probable that this other factor acts by reducing the vital resisting power of the pulmonary tissues, and thus making them vulnerable to the attacks of the microbe. This supposition enables us to account for the development of the numerous cases of pneumonia which cannot be traced to infection from without. The germ being always present, auto-infection is liable to occur whenever from alcoholism, sewer-gas poisoning, crowd-poisoning, or any other depressing agency, the vitality of the tissues is reduced below the resisting-point. We may suppose also that a reflex vaso-motor paralysis, affecting a single lobe of the lung, for example, and induced by exposure to cold, may so reduce the resisting power of the pulmonary tissue as to permit this micrococcus to produce its characteristic effects. Again, we may suppose that a person whose vital power is reduced by any of the causes mentioned may be attacked by pneumonia from external infection with material containing a pathogenic variety of this micrococcus having a potency, permanent or acquired, greater than that possessed by the same organism in normal buccal secretions.—*The American Journal of the Medical Sciences*, July, 1885.

The Treatment of Hemorrhoids by Injection.—In the July number of *The American Journal of the Medical Sciences*, Dr. Kelsey, of New York, again urges the treatment of hemorrhoids by injection of carbolic acid. After an ample experience this has become his routine practice, and in all his cases he has never known a patient to abandon the treatment after it was begun, and he has never failed to effect a perfectly satisfactory cure by it, and he has never had an accident of serious nature with it. He uses three solutions, one of fifteen per cent., one of thirty-three per cent., one of fifty per cent., and sometimes he uses the pure acid. In a severe case he begins with the stronger ones, in a mild case, with the weaker.

A New Remedy in Gouty Obesity and Dyspepsia.—In the *Lancet*, April, 1885, Dr. Mortimer Granville writes that he has been obtaining good results of late, in cases of gouty obesity and dyspepsia, from the use of the salts extracted from ox-bile. They are given to persons with a predisposition to gout, in whom there is a tendency to the deposition of fat in the omentum and elsewhere, coupled with a deficiency of production and maintenance of heat. The bile-salts are given in the form of a pill, each containing about four grains of the taurocholate and glycocholate of soda, and are to be taken with food at each meal.

Chloral in Large Doses in Traumatic Tetanus.—Professor Verneuil records a case of tetanus which occurred in a youth, who was admitted into hospital, ten days after his finger had been crushed, suffering from a moderate amount of trismus. The patient was of robust frame, and in good condition of health when admitted; and was placed in Bonnet's apparatus in order to secure absolute immobility of his body, which was kept at a constant and elevated temperature by being completely encased in wadding. Good diet was given, and constipation guarded against. Large doses of chloral were administered, in sufficient quantities to plunge the patient into a profound sleep. It is necessary to continue giving chloral in doses which shall keep the patient in a kind of continuous coma for from fifteen to eighteen days. The author states that the great benefit derived from chloral in these cases is to give the drug freely for at least fifteen days, and then to gradually reduce the amount each day. The amount usually necessary is from twelve to fifteen grammes daily. The danger in tetanus is due to the extent that the muscles of the larynx or pharynx, together with those of the heart and lungs, are involved. In cases where suffocation, dysphagia, or spasm of the glottis supervene, two methods of treatment are available: 1, the continuous current; 2, tracheotomy. The author concludes by saying that in the next case which presents itself to him, with symptoms of dysphagia, he intends to practice gastrostomy in order to feed the patient.—*Gazette des Hôpitaux.*

Hard Chancre of the Tongue.—Dr. A. Newskji relates the case of a young woman, a virgo intacta, who had a primary sore on the under surface of the tongue. She was a servant in a cheap Russian hotel where wooden spoons were used, and the author believed the infection was caused through that medium.—*Centralblatt für Chirurgie*, April 25, 1885.

The Success of Hypodermic Injections of Quinine in Malarial Fever.—The high price of quinine induced Dr. A. Smirnoff (*London Medical Record*, June 15, 1885) to give an extensive trial to a long list of various substitutes for the classical antimalarial drug. Carbolic acid, salicylic acid, burnt alum, tincture of iodine, tincture of eucalyptus, oil of eucalyptus, oil of turpentine, lemons, and faradization of the spleen, all were resorted to successively, and all of them gave uniformly negative results. With deep regret in regard to waste of time, the author returned to the exclusive use of quinine, striving at the same time to find out a most economical method of freeing the soldier from severe Bessarabian fever in that way. Dr. Smirnoff thinks that he succeeded in finding something like the desideratum in the shape of hypodermic injection of hydrochlorate of quinine, the method which is at present practised by the author to the exclusion of all other means. He injects six grains of the hydrochlorate (dissolved in half a drachm of distilled water) at a time, by means of Lewin's syringe, into the subcutaneous cellular tissue below the scapular region. In the course of 1884 he successfully treated in that way 470 malarial soldiers, the whole number of injections being 1,179; that is, a case required, in average, 2.5 injections; the greatest number of the latter in an individual case was 9. Relapse after the subcutaneous treatment occurred decidedly more rarely than after the internal administration of quinine. That the hypodermic method is much cheaper than the internal one may be gathered from the following comparison. To cure 178 patients treated by the internal use of the alkaloid, the author has used 7,019 grains of sulphate of quinine, or 39.5 grains per head. To cure 470 patients treated hypodermically, he used 7,074 grains of muriate of quinine Taking an eight-grain dose of the hydrochlorate as equivalent to a ten-grain dose of the sulphate, we have an average dose of nineteen grains of quinine in the case of the hypodermic treatment against that of 39.5 grains in the case of the internal administration. The author never saw the appearance of any unpleasant phenomena at the spot of the injection (such as abscesses, sloughing, intense irritation). Pain was always trifling and of short duration. In some of the patients with very sensitive skin there occurred bright redness, about three or four centimetres in diameter, but it quickly disappeared spontaneously. As to the essential advantages of the hypodermic method (besides cheapness), the author points to its applicability at any stage of the disease, and to the sure and safe assimilation by the patient's system of every particle of the drug used.

Suppurative Hepatitis.—Ughetti gives the history of eight cases of suppurative hepatitis. In three, the hepatic abscess was opened externally by incision through the abdominal wall: these cases recovered. In one, recovery followed repeated aspiration. Two died, notwithstanding aspiration and incision. In two, the abscess opened spontaneously by the bronchi, recovery resulting. Among the causes of suppurative hepatitis, wounds are most rare. Dysentery is a much more frequent cause. The hepatitis may be developed contemporaneously or consecutively, therefore possibly there is a common origin to both. The disease, as is well known, is most common in hot climates. It is said that non-acclimatization is a predisposing cause, but in the cases observed by Ughetti this did not appear. All his cases occurred in men, twenty-six being the age of the youngest, forty-three of the oldest. The fever of suppurative hepatitis is variable in intensity and duration. When present it is generally intermittent; often it only appears when the collection of pus is too great for the cavity containing it. In a case published by Ciaramelli (Naples, 1880), there had never been any fever, yet a vast abscess of the liver was found, encapsuled by a thick layer of connective tissue, which prevented the reabsorption of the pus. Discussing the symptoms, Ughetti remarks on the influence of palpation, hepatic pain, pain in the shoulder, jaundice, deeply pigmented urine, etc. As to the diagnosis, he mentions specially the difficulty in certain cases of distinguishing suppurative hepatitis from Naples fever, in which the course of the fever is very irregular. He advises exploratory punctures for diagnosis and treatment. Entire hepatic cells are not ordinarily found in the pus, but may sometimes be obtained on scraping the bottom of the abscess. The prognosis is not as hopeless as most authors assert. In forty-eight cases not operated on, the mortality was seventy-six per cent. In forty-five cases in which incision was practised, the mortality was only forty-two per cent. In thirty-eight cases opening spontaneously by the bronchi, the mortality was only 14.6 per cent. All cases should be operated on as early as possible; peritoneal adhesions are not indispensable. Aspiration is often sufficient to effect a cure.—*London Medical Record*, June 15, 1885.

Lipomatous Polypus of the Gullet.—Dr. J. J. Minkewicz, of Tiflis, details the case of an Armenian, aged fifty-two, who for two years experienced steadily increasing difficulty in swallowing solid food, and of late could sleep only in the prone position, all other postures causing attacks of suffocation. Examination detected a soft, elastic, pyriform tumor, of the size of a large hen's egg, which was attached, by means of a broad pedicle, to the anterior wall of the gullet at the level of the cricoid cartilage. The tumor became visible in the pharynx (just behind the soft palate and tongue) only when the patient performed several successive eructative movements. The author tightened an elastic loop round the pedicle and put two ligatures higher up. On the next day he divided the pedicle between the ligatures, the removal of the new growth being absolutely bloodless. Four days later the patient was discharged well and comfortable.—*London Medical Record*, June 15, 1885.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, July 25, 1885.

AT LAST.

SINCE our last bulletin was written the final change has come to General Grant. He passed peacefully away at eight o'clock Thursday morning. On the morning of the day previous Dr. Douglass summoned Drs. Sands and Shrady to meet him in consultation at Mount McGregor, as General Grant was sinking and death seemed imminent. On their arrival the patient was found in a very prostrated condition, with feeble and frequent pulse, rapid respiration, and inability to swallow. He was suffering no pain, but by his listless manner was apparently conscious that death was approaching. It was decided to sustain his vital powers to the utmost, and make his approaching end as comfortable as possible. The disposition to cough had ceased, and the respiration, although much accelerated, was not mechanically impeded by accumulated mucous secretions. At the time of the consultation he was in his easy-chair, occupied so constantly by him day and night for the past five months.

Toward evening, by his own request, he was transferred to his bed, where he rested quietly until his death. As was anticipated by the medical gentlemen in attendance, he continued to sink despite the stimulants locally applied and hypodermically administered. His fear of a painful and agonizing death was, happily for him and his family, not realized. He simply passed away by a gradual and easy cessation of the heart's action. Thus he was spared much of the suffering which would have been inevitable had his general strength allowed the throat disease to progress in its usual way. For so much, at least, there is reason for thankfulness. At a future time a scientific review of the case will be presented to our readers, giving such data as may be necessary to explain the diagnosis arrived at, and the method of treatment pursued.

TUBERCLE BACILLI IN THE BLOOD AND SPLENIC JUICE IN ACUTE MILIARY TUBERCULOSIS.

IT is a noteworthy fact that some time before Koch's discovery of the bacillus tuberculosis, Weigert had asserted that acute miliary tuberculosis was due to the breaking through of tubercular material into the general current of the circulation. According to the author named, the blood in this way became infected with the specific virus, and disseminated miliary nodules soon made their appearance.

Weichselbaum (*Wiener Medicinische Wochenschrift*, Nos. 12 and 13, 1884) was the first to detect in the blood of three bodies, dead of acute miliary tuberculosis, the presence of the specific bacilli. Subsequently Meisel recorded similar observations for eight additional cases (*Wiener Medicinische Wochenschrift*, Nos. 39 and 40, 1884). It should be remembered, however, that in no instance were bacilli found in great abundance. Indeed, in some cases many specimens of blood were examined with negative results. Nevertheless, Meisel claimed that the presence of these microbes in the blood must be regarded as a constant and pathognomonic sign of the disease.

Meisel further tried to discover the bacilli *intra vitam* by withdrawing in the usual way a small quantity of blood from the fingers of suspected patients. In the only two cases in which this was done, one gave a positive, the other a negative result.

But the same writer also found that the pulp removed by scraping the cut surface of the spleen was comparatively rich in tubercle bacilli. And he suggested that splenic juice might be readily obtained from the living by means of an ordinary hypodermic syringe.

In this way he believed a positive diagnosis could be easily reached.

Acting upon this rather novel suggestion, Dr. Rütimeyer (*Centralblatt für Klinische Medicin*, May 23, 1885) in two cases obtained a quantity of splenic blood-juice for examination.

In the first case, the spleen having been punctured in four different places and twenty specimens having been prepared, no bacilli were discoverable. The patient died sixteen hours after the above procedure, and an autopsy showed that acute miliary tuberculosis was the cause of death. No tubercle-bacilli had been found in the sputum of this patient. It may be added that the spleen was turgid and large, and showed four small rents in its capsule, that were loosely matted to the abdominal walls by recent blood-colored fibrinous deposits. Splenic hemorrhage had not occurred.

In the second case only two punctures into the spleen were made, the patient being almost moribund at the time, and death happening fifteen minutes later. At the autopsy the clinical diagnosis of acute general miliary tuberculosis was amply verified. From the punctured spleen about one ounce of dark blood had escaped. This organ, in addition to countless miliary nodules, also contained numerous cheesy collections of about the size of a pea. In this case an examination of the splenic juice, removed while the patient was still alive, showed in every specimen examined unmistakable tubercle bacilli. In some specimens they were rather abundant, but in the majority of them they occurred sparingly.

Scrapings from the cut surface of the spleen showed great quantities of bacilli. Singularly enough, blood taken from the heart gave negative results.

In spite of the limited number of these observations, Rütimeyer holds that the method may afford valuable evidence in doubtful cases. It is apparent, however, that the procedure has a scientific rather than practical interest. It would hardly be resorted to at the earliest suspicion of miliary tuberculosis, in spite of its seeming harmlessness. Later on, however, it would appear to be

a superfluous infliction on patients whose doom is sealed, whether we can snatch a few bacilli from their yet living bodies or not. And finally, from the evidence now before us, we have no right to suppose that such a discovery is necessarily pathognomonic of the condition in question. Moreover, the absence of tubercle-bacilli from splenic juice does not apparently negative the existence of acute miliary tuberculosis.

A SURGICAL USE FOR ROASTED COFFEE.

Sugar is known to form a tolerably good wound-dressing. Dr. Oppler, of Strassburg, now comes forward with the statement that pulverized roasted coffee is a superior antiseptic. It, therefore, only remains to show that milk makes a good surgical dressing, and the traumatic process will be supplied with a very neat repast.

Oberstabarzt Oppler, in his preliminary communication (*Deut. Militärärtz. Ztsch.*, Heft 6, 1885), states that the powdered coffee is spread over the wound so as to completely cover it. Soft bandages are then applied, and the wound may be left untouched for three or four days. The wound secretions mingle with the powder, forming a protective cover under which the healing process goes on. The antiseptic properties of burnt coffee depend upon the fact that it is in part a vegetable charcoal, and that it contains an aromatic antiseptic oil.

Dr. Oppler's discovery will not divert coffee from its natural use, but, as he suggests, there may often be occasions in which a surgeon may find it convenient.

CREDÉ'S METHOD OF DELIVERING THE PLACENTA.

It will be conceded by all physicians that the conduct of the third stage of labor is frequently the most important duty of the accoucheur. The great importance of thoroughly emptying the uterus of all the secundines is emphasized by the prevalent ideas of the septicæmic origin of puerperal fever. After the pains and trepidation of the second stage of labor are over, the relief and satisfaction experienced by the patient and friends are frequently in contrast with the annoyance of the physician at the non-appearance of the placenta, coupled with an uncertainty as to the most desirable manipulation to hasten its delivery. That much harm may be done by making excursions into the uterus, particularly with fingers not thoroughly antiseptic and by violent massage of the abdomen, cannot be doubted. The method of expectancy that will patiently wait, perhaps for hours, until unaided nature expels the placenta, finds scant favor in this bustling country. Although certain Germans, having continual fear of puerperal septicæmia, may be willing to wait with folded hands great lengths of time, we fancy the average American physician would find it equally difficult to restrain his own as well as the patient's uneasiness at undue delay. Some means or other being employed to hasten the emptying of the uterus, it may be well to notice particularly what constitutes the method of Credé, as many books and writers are rather obscure upon this familiar subject. Simple kneading of the abdomen and more or less severe pressure over the uterus do not, as supposed by some, constitute Credé's method. The object of Credé being only to assist nature, all violent and unnecessary manipulations are to be discountenanced.

As soon as the second stage of labor has been completed, the accoucheur must aim to effect a loosening of the placenta by encouraging the uterus in tonic contractions, and this is best accomplished by "gentle stroking movements over the largest possible surface of the uterus." When *clonic* contractions begin, by which agency the placenta is to be expelled from the uterus, this organ is to be grasped by the outspread fingers and hand, and pressure be made at a time when each contraction reaches its greatest energy. The pressure upon the uterus is to be made in the direction of the hollow of the sacrum. Sometimes in this manner the placenta will be expelled from the uterus with the first contraction, and nearly always by the sixth or seventh pain.

Credé considers that if the placenta has not been delivered within thirty minutes, the case is no longer physiological, but pathological. It is thus seen that this method aims to imitate and aid nature in getting rid of the afterbirth, by exaggerating the contractions with which this is to be accomplished. Indiscriminate kneading and pressure in the interval of the normal clonic contractions is forbidden as unphysiological and wrong. Credé aims to expel the placenta, having the membranes intact, without manual interference within the genital organs. In an article in the *American Journal of Obstetrics*, Dr. Baruch, after reviewing the different plans of managing the third stage of labor, including a thorough description of Credé's method, concludes that the latter should be better understood and practised by American physicians. He would, however, somewhat modify the last stage of the proceeding, by placing two aseptic fingers within the vulva to impede the too rapid descent of the placenta, which is held within the vulva, or partly within the vagina, until the uterus recedes. The mass is then gently removed until the membranes are put upon the stretch, being held in this position while the index-finger gently presses against the membranes, near their placental attachment, until the uterus relaxes its hold upon them, and the whole mass drops. By this plan it is endeavored to insure a complete removal of the membranes.

THE COLLAPSE OF FERRÁN.

Another delusion is gone, and another hope crushed. There is sufficient evidence now at hand to warrant the positive assertion that Ferrán's preventive inoculations for cholera are erroneous in theory and useless in practice. In fine, Ferrán is a gigantic humbug.

Dr. E. Doyen has carefully gone over Ferrán's methods of cultivating the cholera bacillus, and has made a report of his work to the Société Anatomique of Paris. He shows that Ferrán's methods are faulty, and that the life-history which he gives of the comma-bacillus is not correct. He has repeated the inoculation experiments of Ferrán on guinea-pigs with negative results, and he concludes that the Spanish pseudo-Jenner is inoculating his countrymen with a benign form of septicæmia.

We have learned not to place much faith in French cholera commissions, but the report of the last one, which was sent to Spain under the direction of M. Brou-

ardel is worthy of credence. We learn from *L'Union Médicale* that Brouardel has made an official communication to the Académie de Médecine, in which he announces that the performances of Ferrán are not worthy of scientific investigation.

Last of all comes a report from a physician, Dr. La Granjà, who accompanied the Spanish commission to investigate the condition of the cholera epidemic in Valencia. Dr. La Granjà affirms that Ferrán's statistics prove nothing, and that his inoculations do good only in that they allay fear.

The much-talked-of cholera vaccinations, therefore, according to present evidence, are simply inoculations of septicæmia. The physical results, fortunately, have never been dangerous, while the moral effect, it must be admitted, has been good.

THE EVENING POST AND CIVIL SERVICE REFORM.

The practical working of certain phases of civil service reform has apparently made some journals unduly sensitive to even a friendly criticism of this much-lauded system. The *Evening Post* has been much exercised over a statement made by us, on the authority of the principal officer of the municipal civil service commission, that the appointing power is not obliged to select from the three highest names on the examination list, but can choose men standing lower in the scale for appointment to office. While we are concerned more with the working of the system than with the letter of the law, we did not state what was or was not the law on this subject. Our object was only to criticize the practice, and the *Post* retorts by quibbling over the rules.

We do not deny that there is a Seventh Commandment, but if we should attack adultery, and the *Post* should defend the verbal explicitness of the Moral Law (which we greatly fear it would not), the conditions would be very like those in the present controversy.

We stated what we were distinctly informed would be the practical working of the commission, and characterized it as a weak point in the present system. As a matter of fact, the appointing powers have not been compelled to select from the highest names on the list, no matter what the law may state on the subject. In this way it not only has been possible, but actually has happened, that men standing quite low on the list, but having strong political influence, have obtained office. Why does not the *Evening Post*, that is so exercised over civil service reform, look into and criticise the actual working of the system, instead of quibbling over the letter of a law that is not obeyed?

DIET IN HOT WEATHER.

The debilitating effects of prolonged high temperature are nowhere more markedly exhibited than in the gastro-intestinal tract. In infants and young children the great frequency of diarrhœa in summer, is not only due to fermentative changes wrought in their food, but also to the directly depressing effects of the heat upon their susceptible nervous systems. The two elements of improper food and lowered nervous vitality must be considered by physicians in adults as well as in children, although the former do not suffer so seriously, or fatally, as the latter. What is the best kind of nourishment with which to tax the weakened digestive organs during a heated period? The answer is trite, and can frequently be left to the common-sense of the patient. Unfortunately, however, as every physician knows to his sorrow, the possession of common-sense in regard to eating and drinking is entirely lacking in many individuals. To such persons very explicit directions are necessary as to diet. In reference to environment, the prolonged heat of summer affords much the same conditions as obtain in the tropics, where the inhabitants instinctively subsist largely upon vegetables, consisting in a great degree of proximate principles found in the class of carbo-hydrates. Yet many people living in temperate regions continue materially upon the same diet in summer as in winter, and at a time when the atmospheric conditions not only weaken the nervous mechanism of digestion, but curtail physical activity, use the nitrogenous diet that they craved in cool weather, and when taking abundant exercise.

To force albuminous foods in summer is but to surcharge the system with effete products, and overtax the excretory organs in their elimination. Meats, and particularly fats, may then be allowed to occupy a subsidiary place in the dietary, while a large variety of fresh vegetables will be more grateful to the heated body. Different fruits, especially those more or less acid, will likewise prove agreeable as well as healthful. Fresh fish may be relished when meats fail to tempt. In reference to drinks, buttermilk and kumyss may be noted as both refreshing and nourishing, and will frequently agree with a patient when ordinary cow's milk causes indigestion. The small amount of alcohol and slightly acid taste developed in kumyss will often make it acceptable to a stomach that rejects solid food. Indeed, it would be much better for persons overheated to take such drinks as are here mentioned, than to try from a sense of duty to force solids into a stomach that refuses to digest. While ice-water is refreshing and cooling, the enormous quantities indiscriminately consumed cannot fail to do harm. A mouthful slowly swallowed will be found more satisfactory than a gobletful hastily drained. Alcoholic drinks had better be very sparingly indulged in; if they are taken, the light, dry wines will answer best. Plain advice to a patient about simple matters of diet will be just as satisfactory, and much more beneficial, than the dispensing of drugs at this season.

WHAT THE AMERICAN MEDICAL PROFESSION NEEDS.

The profession of this country needs a national association of physicians which shall devote itself to purely scientific work. Membership should be based upon personal character, scientific attainments, and practical experience. It should be for the whole art of medicine what the special national organizations are to their departments. It should devote itself to promoting the medical art and medical science. Questions of medical politics and technical ethics should be left out entirely, for men who are interested in science are rarely interested in these.

An association of this kind, which will bring together

the best men in the country, and which will be, in truth, a representative meeting, would prove of immense benefit. Our leading men could then meet each other, compare experiences, and be subjected to helpful criticism. Methods of practice would become more uniform; progress in knowledge more quickly and widely diffused.

We do not agree with the opinion just now so freely expressed, that the American Medical Association has quite outlived its usefulness and has shown its incapacity. Let that Association devote itself to the object for which it was originally founded, viz., the reform in, and elevation of, medical education; let it deal with the various interesting issues of medical politics. Here is a field in which it may thrive, as is shown by its past. The French Association of Physicians, which deals with these subjects, has been very successful in its line.

News of the Week.

The International Medical Congress.—"The result of this action of the Association has cast a shame and a blot upon the good name of the entire profession in this country, and it has forfeited all the reputation the Association may have had as a fair, liberal, and high-toned scientific body. Under the leadership of a few malcontents the Association has degenerated to the level of a ridiculous and pharisaical institution, utterly unworthy of confidence and respect. So far as the fortunes of the International Medical Congress are concerned it is now evident that the Association is wholly incapable of conducting the Congress under its anspices. The withdrawal of the leading members of the profession from all connection with the present organization tells its own story, and very plainly says, the Congress must be reorganized on some other basis than the one proposed by the American Medical Association if it is to be a success."—*Maryland Medical Journal.*

"The action of the new committee has, as pointed out by the *Medical News*, made of the coming International Medical Congress a meeting of the American Medical Association, with a rather larger number than usual of invited guests. Had the invitation been from the Association alone, there could have been no objection to this, but when, as expressly stated by Dr. J. S. Billings, U. S. A., a member of the original committee, 'the invitation was purposely worded as coming from the medical profession of the United States, and not from the Association only,' the exclusion by the Association from representation in the Congress, of the great bulk of the profession, including a large number of the brightest lights of American medicine, seems, not to put it too harshly, like a piece of unwarrantable assumption."—*Medical Age.*

"When we ask why they take this serious step, we learn that they have, in the first place, a deep distrust of the American Medical Association as an organization which could satisfactorily carry out such an undertaking, and they have a still deeper distrust of the success of any Congress where the best known scientific medical men of the country have been replaced by nominees such as Drs. Cole, Shoemaker, and others. The exclusion of the new-code men is felt to be a serious mistake, as carrying the quarrel of the American Medical Association into the International Medical Congress, and refusing the fellowship of men with whom old-coders in New York are glad enough to consult. All, too, resent the insult offered to such a veteran as Henry I. Bowditch, of Boston, who has devoted half a century to the advancement of the best interests of the profession in the United States. What the result will be it is difficult to predict, but it is hard to see how a Congress can be held without such men as those who have signified their intention of resigning. It would be like a Congress in London without Paget, Lister, Jenner, Gull, Hutchinson, etc."—*Canada Medical Journal.*

"If these men had first taken pains to learn accurately what the present Committee had done, and then assembled for the purpose of considering the more important items with a view of suggesting improvements, and thereby aiding the Committee in rendering their work more complete and acceptable, they would have given evidence that they had more regard for the honor and interests of the profession than for their own personal prejudices and dislikes; in other words, they would have acted like *men*, and not like half-grown school-boys. Although the assembly of twenty-eight in Philadelphia, the nineteen [twenty-four] in Boston, and the twelve [thirteen] in Baltimore [and thirteen in Washington], [add also St. Louis, Louisville, Lowell, Mass.; Newburyport, Mass.; Portland, Me.; and New York City], each solemnly adopt preambles and resolutions, not one of them specifies any particular provisions or rules that had been adopted by the Committee on Organization, the practical working of which would prove 'detrimental to the profession in America,' or in any other country."—*Journal of the American Medical Association.*

A Political Cure for Medical Pauperism.—In England the law says that a man who seeks medical relief of the parish shall not vote. Taking advantage of this, the friends and promoters of provident dispensaries are urging the claims of their institutions. The Metropolitan Provident Medical Association of London has eleven dispensaries, of which four are self-supporting. In them 25,000 persons are treated annually for about $16,000. This is decidedly cheap, but it is better than the average dispensary of this city, which will treat the same number of cases for about one-third the sum. It is perfectly useless, however, to think of applying the stimulus of disfranchisement to medical paupers in this country. But it would be interesting, if such a proposition were seriously made, to see how effectively the pot-house politician could work up the bird of freedom, the Declaration of Independence, and the sacred rights of the people into a medico-political thesis.

The Kleptomania of Pregnancy.—*The Lancet* makes this sensible annotation upon an interesting subject: "A lady, the wife of a merchant, was lately charged before Mr. D'Eyncourt with shoplifting. Her physician deposed that he should not consider her morally responsible for what she had done, as she was near her confinement, and in a peculiar condition. Her brother-in-law deposed that he had lately noticed a change in her. On these grounds, the prosecutors not pressing, the magistrate allowed the case to be withdrawn, remarking that

had not the accused been so near her confinement he should certainly have sent the case for trial. We are not disposed to quarrel with this decision. Moral obliquity is sometimes certainly associated with pregnancy, and the ordinary motives for unlawful annexation were here undoubtedly absent. Distinguished persons, whose sex debars them from this explanation, have been chronically afflicted with this disease, and yet have never found themselves in the durance to which they have felt it their duty to sentence others who merely took things which they required. The subject is a difficult one, but we should be glad to see reports of kleptomania among the poorer classes, who often inherit a strong tendency to thieving, recognized as such and treated accordingly."

The Danger of being an Anti-vivisectionist.—M. Magnan cites a number of cases of madness among anti-vivisectionists. One woman first renounced animal food, then took in all stray dogs, and finally went round to the butchers, begging them not to slaughter any more cattle. She became finally mad, and was received as a patient at Charenton.

The French Association for the Advancement of Science will meet at Grenoble, August 13, 1885, under the presidency of Professor Verneuil.

A Serious Epidemic of Whooping-cough has run through the islands of the Fiji group. The malady has carried off all the very young native children, and left a decrease in the population of 3,000. A few years ago 30,000 persons in Fiji died from an epidemic of measles.

Cremation in Paris.—Current reports give it that cremation in Paris will soon be available for the general public, at the small cost of $2.50 for each operation. An experimental furnace is being constructed at Pére-la-Chaise on the principle of the crematories at Rome and Milan.

The Museum of the Royal College of Surgeons in London has been enriched by the addition of the skeleton of the large St. Bernard dog "Chang," immortalized in *Punch* by his owner, Mr. George du Maurier, by whom he was presented, on his death, in October, 1883.

Death of Dr. Joseph H. Bill, U.S.A.—Lieutenant-Colonel Joseph H. Bill, Medical Department, United States Army, died on July 21st at Yonkers. He was appointed an assistant surgeon in the army in April, 1860. In March, 1865, he was brevetted Major and Lieutenant-Colonel for faithful and meritorious services during the war, and in the following month was given the full rank of Captain. In July, 1866, he was promoted to be Surgeon, with the rank of Major.

New Buildings for the Medical School in Paris.—The opening of the new buildings called the École Pratique de Médecine, and which form part of the School of Medicine of Paris, occurred on July 14th, the national fête day.

Another Cholera Commission.—Dr. Graham Brown, of Edinburgh, has left for Spain in company with Drs. Roy and Sherrington, with the intention of carrying on further investigations upon the etiology of cholera, and the relation to it of Koch's comma bacillus.

Another Mydriatic, Mandragorine.—M. Crouzel has isolated a body having all the properties of an alkaloid from the mandrake (*Mandragora officinalis*). This body forms a sulphate which is crystalline. A solution of this salt was found to have marked mydriatic effects on the eye of a rabbit.—*L'Union Pharm.*, p. 264.

A Monument to Thuillier, a member of the French Cholera Commission in Egypt, who succumbed to the disease while pursuing researches in that country, was formally unveiled recently at the École Normale in Paris, in the presence of the Minister of Public Instruction. M. Pasteur presented the monument in the name of the subscribers, and paid an eloquent tribute to the memory of his former colleague.

John McCullough's Insanity.—It is as clear as the open day that Mr. McCullough is insane, and he probably has general paresis. There is something very cumbersome and expensive in the legal machinery which requires a commission to sit for a week in order to elicit a plain fact, as has been done in Philadelphia lately.

Limiting the Number of Hours for Shop-assistants and Clerks.—A bill has been presented to the British Parliament to regulate the number of hours of work that may be required of shop-assistants and clerks in that country. In 1870 an act was passed by Parliament called the "Factory and Workshops Act," which regulated the work-hours in factories and workshops in which young people are employed. Taking the ground that young persons employed in shops and stores are as much entitled to protection as those others, Sir John Lubbock has introduced the bill referred to above. It has been estimated that the average working week of shop-assistants is from seventy-five to ninety hours.

Is this True?—The *Journal of Commerce*, in its issue of July 9th, says: "With all its weakness and indecision the International Sanitary Conference at Rome had sound ideas upon some questions referred to it for judgment. Its adjournment to November next has postponed the official publication of any of the conclusions of the Conference. But the correspondents of several English and Continental journals, who took notes of the proceedings, agree in the statement of one important opinion at which the Conference had arrived. It was decided that the 'disinfection of merchandise and mails is superfluous.' No exception of rags was made, and the verdict of the Conference was understood by all present to include rags, which are well known and important articles of traffic between countries." If we are correctly informed, the above is, if not a mistake, an extremely misleading statement. We believe that the Technical Committee, whose opinion alone would have any weight, expressly approved of the disinfection of rags.

The Progress of the Cholera in Spain.—The number of deaths from cholera in Spain was estimated to be over 10,000 up to July 11th, and over 18,000 up to July 19th, while to-day it is probably not far from 25,000. This mortality represents over 50,000 cases of the disease. The daily number of new cases, as reported, averages about 1,700, with between 600 and 700 deaths. New provinces are being constantly invaded.

The Death-rate in this City, so far this summer, has been below the average. This is due in part to the cool weather which we have had up to the present week, but also to the vigorous work in sanitation which the cholera scare brought about.

Autotype Reproduction of Harvey's Manuscript Lectures.—We gladly take the opportunity to call attention to the efforts which Dr. Edward H. Sieveking is making to secure the publication of an autotype reproduction of Harvey's manuscript lectures. Regarding them, Dr. Sieveking communicates the following interesting facts: "The manuscript of the original lectures delivered at the Royal College of Physicians by William Harvey, including his earliest observations on the Heart and Circulation, and pronounced by him in and after 1616, were re-discovered in the British Museum in 1877. I gave a description of the little book, and exhibited an autotype copy of one page, in my Harveian Oration at the College, in 1877. I then suggested that it would redound to the honor of the present generation, and be an advantage to the history of medicine, if the whole of the lectures could be published in autotype, accompanied by an intelligible transcript. The handwriting is so crabbed and there are so many abbreviations, that no one but an expert could succeed in understanding the lectures. Without the valuable aid of Mr. Bond, now the Chief Librarian of the British Museum, I should have failed in my attempts to understand much, if anything, of the lectures. By dint of much labor, Mr. Bond succeeded in interpreting one of them, and has now been good enough to make me acquainted with a gentleman who is able and willing to transcribe the whole of the lectures. My inquiries led me to suppose that no publisher could be found to undertake the risk of publication, in the form proposed, unless guaranteed a certain amount of professional support. On the other hand, I calculated that if from two to three hundred gentlemen would engage to take one copy each, at the price of not more than two guineas, the work might be safely proceeded with." Any gentlemen who are willing to support the project are requested to send their names to Dr. Sieveking, No. 17 Manchester Square, W., London.

Death of Dr. John Staige Davis.—Dr. John Staige Davis, Professor of Anatomy and Materia Medica at the University of Virginia, died, on July 18th, of paralysis, at Charlottesville. He was born October 1, 1824, in Albemarle County, Va., and was educated at the University of Virginia, from which he was graduated and received his diploma of M.D. in 1841.

The San Francisco City and County Hospital.—Some weeks ago this hospital was investigated by the Grand Jury with the result of suggesting: *First*, that the time of the visiting physicians will be more profitably spent "in prescribing for the patients," than in lecturing to the students. *Second*, all physical examinations in the presence of students are objectionable. *Third*, the connection between the hospital and the medical schools should be severed. The *Pacific Medical and Surgical Journal* regards these criticisms as eminently narrow and unjust.

The Death of Professor Paul Vogt, of the University of Greifswalde, is announced.

Professor Bamberger has been appointed Rector Magnificus of the University of Vienna.

Mr. Ernest Hart, editor of the *British Medical Journal*, is to run for Parliament as a Radical. We learn that he has consented to oppose the enactment of the Contagious Diseases Acts, and as this position is not that taken by the *Journal*, it may lead him to resign. We wish our editorial confrère success in his new venture.—Professor John Eric Erichsen will also seek parliamentary honors at the next election.

The French Commission and Ferrán's Inoculations.—The French Commission, under Dr. Brouardel, went to Valencia, but returned very soon. It is reported that they found nothing in Ferrán's methods worthy of scientific research.

The International Medical Congress.—Dr. Oliver Wendell Holmes, Dr. William H. Baker, Dr. Cheever, Dr. James C. White, Dr. William F. Whitney, of Boston; Dr. E. P. Hurd, from Newburyport, and members from Concord, N. H.; Portland, Me.; and Lowell, Mass., have resigned from membership in the Congress. The physicians of this city belonging to the State Association have held a meeting and proffered a plan for a compromise to the Executive Committee. This plan is substantially that of allowing only Old Code physicians to become delegates, with power to vote, while New Code physicians will be permitted to become members with power to contribute papers, but not to vote. This is virtually no compromise, since no self-respecting physician would accept membership or do work under such conditions.

Testimony to the Moral Effect of Cholera Vaccination.—A contribution regarding the cholera in Spain, addressed to the American Minister at Paris by Dr. W. E. Johnson, has been received at the office of the National Board of Health through the Department of State. Under date of June 13th, Dr. Johnson writes: "A circumstance which has up to the present moment given a great feeling of security in regard to the disease is the fact that both in Spain and France the mass of the people, the peasants and all the poorer classes, have adopted with a perfect confidence and with great enthusiasm the theory of inoculation proposed by the Spanish surgeon, Ferrán. The very classes of people, fortunately, who are the most exposed by their habits of life to the ravages of the epidemic are those who have seized upon the new idea with the greatest ardor. . . . The idea that a cure, or, more properly speaking, a prophylactic to the disease has been discovered is contributing largely to its non-extension by the greater feeling of security it gives, by the more elevated moral tone it creates, and by the absence of that general and most fatal demoralization which seizes upon the people of infected or threatened localities, and abstracts from them one-half of their vitality before being struck by the dreaded malady. For these reasons there is a more cheerful, and especially a more healthful, indifference in regard to the epidemic than has ever before been observed. But the municipal authorities, fortunately, are none the less zealous on that account in enforcing the necessary sanitary measures for combating the extension of the disease."

Reports of Societies.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, May 1, 1885.

A. Brayton Ball, M.D., President, in the Chair.

HEARING BETTER IN A NOISE.

Dr. Samuel Sexton related the history of a patient whom he expected to show to the members, but the inclemency of the weather had prevented his presence. The case began as a destructive inflammation of both ears from scarlet fever, while the patient was but seven years of age. In his youth he was quite deaf, but hearing began to return as he grew up to manhood. Finally he went as fireman on a railroad locomotive, and advanced to the position of engineer. For many years he ran an engine without there being any complaints made, and without regarding himself as deaf. But when the custom was introduced of examining railroad employés regarding their ability to hear well, he was dismissed. Being thus thrown out of employment, and having nothing to do, he drifted into the Eye and Ear Infirmary. On examination Dr. Sexton found that he could not hear a loud voice at a distance of only a few feet, and was unable to understand anything which was said to him. But he made the statement that when on an engine in motion he could hear everything; could hear better than the fireman, whose hearing was normal. But the moment he got off the train and went to the company's office, he could hear nothing that was said to him.

The point of particular interest in the case was that which raised the question whether these people could be benefited by artificial drum-heads to such an extent as to enable them to continue their vocation. He introduced an artificial drum-head into one ear of this patient, and much to his surprise the man was immediately able to hear ordinary convervation. The next time he returned to the dispensary, the man had obtained a place as stationary engineer. A drum-head was then placed into the other ear, and he was enabled to hear with that ear also.

Of course it was not in every case of deafness that an artificial drum-head would prove of benefit; indeed, the cases were few in which persons would be enabled by this means to continue their occupation, where it was necessary to hear well. It was only in cases in which the drum-head partially remained that such a device was of service.

Dr. Walker asked whether the drum-head was usually lost in cases where a man was able to hear better in a noise.

Dr. Sexton replied, not at all; in the greater number of cases of chronic catarrhal inflammation the drum-head remained. Where a patient heard better in a noise, the drum-head usually was present, but it was very loose; the equilibrium having been lost, there was consequent defect in the transmitting mechanism. In such cases, low vibrations, such as were experienced in a carriage or railroad train, drove the drum-head in, brought the ossicles close together, other sounds were taken up, and the subject was able to hear very well. In the case related, only the upper segment of the drum-head was present, which failed to drive the ossicles in except during the presence of strong vibrations.

A discussion was then opened on

THE COMPLICATIONS AND SEQUELÆ OF SCARLET FEVER.

Dr. Kinnicutt opened the discussion by referring to a

PERSISTENT ELEVATION OF TEMPERATURE IN SCARLET FEVER.

The speaker had mentioned at a previous meeting of the Society that he had frequently observed, in *apparently* uncomplicated cases of scarlet fever, the persistence of a slight degree of pyrexia into and even to the end of the third week. The pyrexia might amount to no more than a degree or a degree and a half in the afternoon, with a normal morning temperature often. The morbific action of the scarlet fever poison evidently was not exhausted, and it behooved us in such cases to make frequent and thorough examinations of our patients. The serous membranes, in his experience, were structures often involved after the more palpable signs of the disease had disappeared, even during apparent convalescence; and of these, the articular synovial membranes and the endocardium most commonly. It was unnecessary before this Society to insist upon the great frequency with which the former were affected; nevertheless it was a pathological condition not sufficiently well recognized by physicians. The explanation was simple; inflammations of the articular synovial membranes in scarlet fever in children, as a rule, were unattended with swelling, redness, or spontaneous pain; the sole symptom often was pain on movement of the joint.

Dr. Kinnicutt believed that the endocardium was involved more frequently than was commonly supposed. In his daily examinations he had frequently detected an impurity of one or another heart-sound, not infrequently a soft, but distinct murmur. Undoubtedly in many cases the murmur should be regarded as hæmic in origin or due to a temporary dilatation, nevertheless such a sign in the course of scarlet fever always should be received with suspicion. It was probable that such an endocarditis might disappear leaving no traces behind it, yet it was important to bear in mind that it might well lay the foundation for future chronic cardiac disease.

Occasionally he had been able to keep under observation such cases as he had described for a number of years, and had seen valvular disease develop. He believed that many cases of heart-disease in children and adult life might thus be explained. Dr. Kinnicutt was not disposed to regard the joint symptoms as *truly rheumatic* in nature, rather as inflammations of serous membranes dependent upon the action of the specific scarlet fever poison. In conclusion, he stated that, where pleuritis and pericarditis with effusion were developed, there was a marked tendency to rapid purulent change.

The President had been very much interested in what Dr. Kinnicutt had said regarding the cardiac symptoms of scarlet fever, and concurred with him in the belief that they should always excite strong suspicion of their being of rheumatic origin, but he did not think that we should necessarily take an unfavorable view of such cases as we were sometimes tempted to do, and to give a very unfavorable prognosis. In the last case of scarlet fever which he had seen there was well-marked joint rheumatism, accompanied by apparent endocarditis; that is, there was a very well-marked mitral systolic murmur, and the pulsations of the heart were somewhat irregular and rapid, beating from 120 to 130 per minute during ten days or two weeks. There was not much elevation of the temperature. Dr. Ball felt uneasy about the case, but was inclined to take the view that the murmur was anæmic, for the reason that it had come on after the boy had been very ill with scarlet fever for two weeks, and was much prostrated from the disease. Percussion showed the heart to be larger than normal, and he thought there was possible dilatation of the left ventricle, allowing reflux through the mitral valves. In the course of a month after recovery, the cardiac murmur disappeared entirely, and the heart returned to its natural size.

LONG CONTINUED RAPIDITY OF HEART ACTION.

Dr. Simon Baruch, by invitation, related the history of a case of scarlet fever with a complication which, so far as as he was informed, was novel. The patient was a merchant, thirty-five years of age, who had always been in perfect health until two or three days before Dr. Baruch saw him, which was on the 5th of April. At that time the temperature was 103° F.; the pulse, 140. At 9 P.M. the pulse was 150. April 6, 12.30 P.M., temperature, 104.5° F.; pulse, 150. Half a drachm of antipyrin

was administered. At 2.15 P.M., temperature, 101° F.; pulse, 150. At 3.30 P.M., temperature, 101° F.; three drops of fluid extract of digitalis administered. 5.40 P.M., temperature, 102° F.; pulse, 150. At 6 P.M. half a drachm of antipyrin given under misapprehension of instructions. 7 P.M., temperature, 101° F.; pulse, 150. Brandy was given, and more digitalis. April 7th, 4 A.M., pulse, 150. Digitalis, four drops, and brandy administered. At 7 A.M., temperature, 102.5° F.; pulse, 150. Antipyrin, thirty grains; at 7.30 A.M., digitalis, five drops. 11.30 A.M., temperature, 102° F.; pulse, 150. There had been no effect evidently from the antipyrin. At 2 P.M. a consultation was held with Dr. A. Jacobi, and on account of the continued high pulse-rate an unfavorable prognosis was made. In the course of the afternoon several large doses of caffein were given hypodermically and in capsule, and brandy freely administered. At 5.30 P.M., the pulse 150; and at 7.30 P.M. the pulse 140; temperature, 102° F. Infusion of digitalis was admnistered in half a tablespoonful doses, and alternated half hourly with camphor, caffein, and brandy. At 9.30 P.M., temperature, 102° F.; pulse, 130. Pulse-rate increased during the evening, until at midnight Dr. Baruch's assistant, who had remained with the patient, found the pulse 180, barely to be counted, and called Dr. Baruch, who at 12.30 A.M., April 8th, found the pulse 140. Caffein and digitalis were discontinued; half an ounce of brandy with milk was given and later a hypodermic injection of morphine. At 12 M., April 9, temperature, 101° F.; pulse, 130. Half an hour later the pulse was 120. He had taken neither caffein nor digitalis, and only small quantities of brandy and camphor. At 9.30 P.M., temperature, 100.8° F.; pulse, 128. April 10, 7 A.M., temperature, 101° F.; pulse, 114; at 11.30 A.M., temperature 100.5° F.; pulse, 108. April 11, 3 A.M., pulse, 98; temperature, 99° F.

Dr. Baruch regarded the pulse-rate in this case as phenomenal because there were no other symptoms indicating the extreme gravity of the case which would be inferred from the condition of the heart. There was a full and free eruption, but no severe angina. The sensorium was clear throughout. The temperature was not especially high. The patient took from three to six quarts of milk every twenty-four hours, besides his brandy. The rapid pulse was not due to heart-failure, because it occurred at the outset of the disease in a man who was in perfect health on the day immediately preceding the invasion. Moreover, both sounds of the heart were clear and distinct even when the pulse was 160; this in itself is a remarkable phenomenon in my experience. Indeed, recovery of a man after exhibiting repeatedly a pulse-rate of 160 has never occurred to me before. The rapidity of the pulse was independent of the height of pyrexia; it was present with a temperature of 101° F. or 104.5° F., whether the temperature was reduced by antipyrin or fell spontaneously, and it continued until the natural decline of the disease, even during the early days of desquamation.

I regard the phenomenon as an effect of the scarlatinal poison expending its intensity upon the vagus and inhibiting its action. This inhibition continued, being but slightly, if at all, influenced by remedies until the exanthema began to decline, and it continued in operation when the temperature was almost normal. When the patient was quite comfortable, taking six quarts of milk daily and demanding more food, when the temperature was 99° F., just after desquamation had begun, the pulse continued at about 100. Yesterday it was 80, after considerable exercise, the patient having visited my office without permission.

Dr. Sexton inquired as to how much brandy the patient had taken.

Dr. Baruch said a moderate amount of brandy had been given before he saw the patient, and thinking that might have had something to do with causing the rapid pulse-rate, it was stopped for awhile, but no effect was noticed upon the pulse.

Dr. Kinnicutt thought it would have been interesting had the effect of hypodermic injections of convallaria been tried in such a case. He had found that convallaria acted better in such cases than any other form of cardiac stimulant which he had used; certainly better than digitalis, although he did not regard it in general nearly as efficient a heart tonic. It seemed to him that in cases in which there was present an inhibitory action of the vagus, convallaria was the most effective means of controlling it. Cases had been reported at this Society in which hypodermic injections of convallaria had controlled rapidity of heart action, 160 per minute, after digitalis and other purely heart tonics had failed. Drs. Peabody and Polk reported cases illustrating the beneficial action of convallaria in increased rapidity of heart action in other cases than acute disease.

Dr. Dana asked whether the man had ever before had any cardiac affection.

Dr. Baruch replied that he had never before been sick.

DIPHTHERIA COMPLICATING SCARLET FEVER.

Dr. Baruch said that formerly he was inclined to regard diphtheria as rather a common complication of scarlet fever, much more so than it really is. The mistake which he formerly made, and which many probably made, was due to lack of thorough study of supposed cases of diphtheritic complication of scarlet fever. Although he did not doubt the occurrence of diphtheria as a complication, he had not seen a case of post-diphtheritic paralysis. It is important to distinguish true diphtheria from the ordinary angina of scarlet fever. The latter is a necrotic process; the former is not. In cases in which he was unable to find false membrane upon the velum and the pillars of the fauces, or albumen in the urine, he was unwilling to make a diagnosis of diphtheritic complication. The muco-purulent deposits of scarlet fever looked very much like the deposits of diphtheria, and were often mistakenly regarded as such, leading us to make a much more serious prognosis. Only three weeks ago a young man of twenty-one years came to his dispensary class with sore throat, which, on examination, was found to be sore throat of scarlet fever. A child of twelve years was brought on the same day, the trouble being found to be scarlet fever, which had not been suspected.

EAR-COMPLICATIONS OF SCARLET FEVER.

Dr. Baruch had of late years made more or less a special study of throat and ear disease, and had come to the conclusion that the throat affection in scarlet fever, because of its liability to extend into the Eustachian tube, should receive much more energetic treatment than was usually given it. He also thought that a good many cases of naso-pharyngeal catarrh and chronic follicular tonsillitis arose from scarlet fever. Dr. Baruch treated the cases by the free use of antiseptics and cleansing methods, by ice-bags to the throat, and by tinctura ferri internally, thus guarding against future throat trouble. He had been a general practitioner for fifteen years before he had studied the ear and throat specially, and during that time had given, as he believed general practitioners usually gave, too little attention to the recognition of the early stages of inflammation of the middle ear in scarlet fever. Such a complication often escaped the physician's notice, because it was apt to occur during the desquamating period, when the physician had ceased regular attendance. Besides, the general public was apt to regard a discharge from the ear after scarlet fever as a favorable sign, and did not consult a physician for that reason. Finally the patient entered an institution, or consulted a specialist for treatment of the chronic affection. It has been ascertained by statistics, that ten per cent. of the cases of deaf-mutism were traceable to scarlet fever. This fact, combined with the long suffering inflicted by chronic suppuration of the ear, should cause us to be

constantly on the alert for complications in scarlet fever. If during the desquamating process (it occurs usually in the early days of this period of scarlet fever) the child complained a little of earache, or if there was a slight rise of temperature, our attention should be directed to the ear, and if, by touching the mastoid process or the helix, it is ascertained that pain is present, the drum should be examined. If acute catarrh is found to exist, it should be treated energetically. He thought applications of warm water into the ear, not by syringe, but by pouring from the spout of a tea-kettle or low irrigator, very useful. The throat should again be looked after, and thoroughly cleansed by antiseptics. Even the application of leeches becomes necessary, for the slight loss of blood would not endanger the patient's condition, while the integrity of the ear is all-important.

With reference to the sequelæ he had found a form of anasarca, not due to implication of the kidneys, not infrequent. There was no albumen in the urine, nor microscopic elements pointing to renal complication; the dropsy was not accompanied by ascites, the abdominal cavity usually being free. He supposed it to be an œdema due to protracted disease, the heart having been working hard, with perhaps some degree of failure. He had seen this form of anasarca often after long protracted malarial fever, even when there was no infarction of the liver to account for it. The treatment indicated was iron and hygienic tonics. It is important to differentiate this form of dropsy from the ordinary post-scarlatinal, on account of the difference in prognosis.

Dr. Baruch further added, regarding the chronic inflammations of the ear following scarlet fever, that they had always proven very rebellious until he had adopted the dry antiseptic method; the canal was syringed with warm water, dried with cotton, and packed with finely powdered boracic acid. The frequent use of the syringe he regarded as harmful, even in cases of six months' standing, or longer, in which there was no organic disease of the bones of the ear. He has seen the condition disappear rapidly under this form of treatment.

ABSENCE OF NERVOUS COMPLICATIONS OF SCARLET FEVER.

Dr. Dana said that his contribution to the subject under discussion would be rather of a negative character. Scarlet fever, so far as his observation went, was a disease characterized by absence of nervous sequelæ. In looking over the notes of about three hundred and forty cases of nervous disease of all kinds, occurring in children, which had appeared at his clinic during the last three or four years, he could find only one case of nervous trouble which seemed to be a sequela of scarlet fever; it was a case of chorea occurring in a boy of only partial mental development, and there was some doubt whether the attack of scarlet fever had had much to do in causing the nervous affection. Perhaps it precipitated the choreic trouble in a child who had originally of a neuropathic tendency. The experience of other neurologists he believed to be about the same. In looking over cases of infantile spinal paralysis, he found that in seventy-five tabulated cases only two were put down as having had scarlet fever. Most authorities said there was no paralysis after scarlet fever, or at least no good evidence was given of paralysis produced by that disease. His observation was like that of Dr. Baruch, namely, that diphtheritic sore throat was very rarely a complication of scarlet fever, for the diphtheritic paralysis very seldom followed scarlet fever. Bonn says he has seen, as have other observers, paralysis of the throat only very rarely after scarlet fever, and he has never seen any of the other forms of paralysis, such as occur after diphtheria. Dr. Dana was inclined to lay down, as a fundamental rule, that the infectious poison of scarlet fever does not cause the neuritis or myelitis which is observed as an effect of the poison of diphtheria.

Some exception might be taken as regarded epilepsy. Gowers found 19 cases (among 1,450) in which recurring epileptic convulsions occurred after scarlet fever. Of these uræmic poisoning could be excluded in 14 cases. The possibility of meningitis, however, is not alluded to. Dr. H. A. Wildermuth has also very recently in *Der Irrenfreund*, reported cases in point. Among one hundred and eighty-seven epileptics, the exciting cause of the disease in twelve cases was scarlet fever, but of these twelve, in six there were evidences of a leptomeningitis, of the convexity, in five there was albuminuria, and in three of these the convulsions were evidently uræmic, for they did not recur after cure of the renal trouble. Dr. Wildermuth, in opposition to Gowers, comes to the conclusion that the specific poison of scarlatina does not itself directly excite epilepsy. This was Dr. Dana's view also.

Dr. Kinnicutt said his experience had been similar to that of Dr. Dana and Dr. Baruch; he had never seen any nervous symptoms except in cases in which there was undoubted diphtheritic complication.

The President asked Dr. Baruch how he distinguished the membrane of diphtheria from the appearance of the scarlatinal sore throat.

Dr. Baruch said he paid less attention to the appearance of the membrane than to the other symptoms present. He thought the membrane in the two conditions had much the same appearance; but in the sore throat of scarlet fever the soreness was much more marked; there was more difficulty in swallowing, and the local symptoms were more intense, because there was destruction of the epithelium going on. Again, in the diphtheritic complication the membrane was not confined alone to the lateral portion of the pharynx and tonsils; it also existed on the posterior pharynx, velum, and pillars. If it occurred upon the velum he should feel quite sure that it was diphtheritic. In addition he should examine the urine.

The President asked if the diphtheritic membrane was not much more adherent than the pultaceous membrane of scarlet fever. Then again, the false membrane was usually in isolated patches.

Dr. Baruch thought the contrast would hold good between the diphtheritic membrane and the peculiar secretion which oozed out of the follicles in scarlet fever. The latter was much more easily removed. But the mucopurulent discharge which occurred upon the ulcerated surface in scarlet fever is pretty hard to remove—quite as difficult to remove as the diphtheritic membrane. He did not think the difficulty of removal of the membrane would be a diagnostic element of itself.

The President regarded diphtheria as a rare complication of scarlet fever, and agreed with Dr. Baruch in not regarding the false membrane described by Dr. Baruch (as belonging to uncomplicated scarlet fever) as diphtheritic at all.

Dr. Beverley Robinson said that the complication which he had personally observed most frequently in scarlet fever was otitis and perforation of the drum-head. But then he had not seen a very large number of serious cases of scarlet fever. He had not often seen diphtheritic complications, not oftener than once or twice. He had seen three or four cases of perforation of the drum-head, and although he had been fully alive to the possibility of the accident, and its importance, yet there were no symptoms which enabled him to recognize the otitis until perforation had occurred. For his part he believed that perforation of the drum-head could not always be prevented, and this statement was true not only of scarlet fever, but also of diphtheria. The only prevention, if it could be called such, was to perforate the drum-head so that the matter could escape, should it accumulate, without spontaneous rupture.

Dr. Kinnicut asked Dr. Sexton if he would approve of the early performance of paracentesis in such cases.

Dr. Sexton replied that he had not practised it, and should regard it as an uncalled for procedure except under very limited circumstances.

Dr. Kinnicutt said that one of his patients had had scar-

let fever and, on complaining of trouble in the ear, a friend advised paracentesis within two hours after the first symptom. Relief was instantaneous after the operation. This occurred at about the end of the first week of the fever.

Dr. Sexton said he could understand that where the drum-head is thickened, as it may be from previous inflammation, immediate relief may follow perforation, but there are many cases in which the inflammation is not confined to the tympanic cavity proper. The membrana tympani and the membrana flaccidi were two quite different things; where there was much bulging in either perforation was sometimes necessary, and might give prompt relief. But the membrana tympani very seldom called for such a procedure.

Dr. Kinnicutt asked Dr. Sexton whether any particular form of treatment was indicated to prevent the ear complication.

Dr. Sexton thought that in nearly all cases of scarlet fever one would find on examining the ear that there was a catarrhal inflammation of the membrane lining the drum-head during the existence of the throat trouble, but it does not always proceed to suppuration. The mucus, if in excess, may escape through the Eustachian tube, which is of large size in children. Unless there are special symptoms, attention is not directed to the ear, but if there is a suppurating tendency he would not hesitate to give very small doses of calcium sulphide to the child. He never failed to get benefit from that.

Dr. Kinnicutt. With local applications?

Dr. Sexton. Without local applications. I think it quite hazardous to make local applications. One cannot be too careful in syringing the ear. The water is liable to increase the irritation. Where there was a simple, non-irritating discharge, Dr. Sexton found but little trouble in cleansing the ear. If the discharge were purulent and irritating, he used cotton-wool. The treatment would vary with the age of the patient. In very young children, in whom the drum-head is difficult to find, very little can be done in the way of making an examination. After puberty the pneumatic cells take to form in the mastoid, and the complications were likely to be different. Dentition was often going on in scarlet fever, and was liable to predispose to ear-trouble by sympathetic hyperæmia. He would like to hear the experience of the members concerning meningitis as a complication of scarlet fever, which he believed was regarded as an extension of disease from the ear.

Dr. Baruch asked Dr. Sexton whether he would use Politzer's method early in this class of cases.

Dr. Sexton replied that ne never used it in the early stage.

Dr. Baruch asked how soon he would employ it after perforation of the drum-head.

Dr. Sexton said one should be very careful in its use. It should not be employed too freely through fear of interfering with the healing of the drum-head. After the membrane had healed and there was possible danger of its becoming adherent to the walls, it might be used, but very carefully, through fear of again producing rupture.

Dr Baruch asked if it was not important to keep the tube clear.

Dr. Sexton said it was desirable to keep the tube clear, but this was not assured by the use of the air douche, and where there was perforation of the drum-head there was usually free drainage.

Dr. Dana asked Dr. Sexton if careful treatment of the throat difficulty would prevent implication of the ear.

Dr. Sexton replied that the throat and ear trouble almost always occurred simultaneously. Dr. Sexton further stated that in many cases of ear trouble, which the patients attributed to scarlet fever, close questioning brought out the fact that it did not occur at the time of the exanthem at all, but was independent of it. Then there were chronic cases of ear disease following an acute otorrhœa which had not been recognized because of the patient's youth. Such cases were liable to be called cases of congenital deaf-mutism.

Dr. R. F. Weir had several years ago made a special study of ear affections, during which time he saw a good many cases of aural disease following the exanthemata, and he could corroborate the statement of Dr. Robinson, that it was very difficult to recognize the ear trouble in these children before perforation took place. Besides, in a child under five years of age, it was very difficult to make an examination of the ear which would enable one to pronounce a positive diagnosis. Another fact which made the examination difficult was the liability to extension of the inflammation to the external ear. He had therefore been unable to carry out his ideas as to the propriety of paracentesis in these cases, oftener than once or twice, and on those occasions there had been considerable distress present. It was very difficult to perforate the drum-head in these cases. It was a haphazard operation. Suppuration of the middle ear in the young suffering from scarlet fever, if properly treated, resulted in the majority of cases in a satisfactory cure.

Dr. Weir, Dr. Baruch, and Dr. Kinnicutt had relieved pain in the ear by the use of a solution of cocaine. Dr. Kinnicutt spoke of a case in which a drop or two was supposed to have come in contact with the external canal and produced inflammation.

Dr. Robinson asked the experience of the Society with regard to the value of cold affusions as a means of lowering excessive temperature accompanied by nervous excitement in scarlet fever.

Dr. Kinnicutt had used cold affusions and found marked benefit therefrom. Dr. Buck had reported a case in which cold affusions failed to lower the temperature, while hot affusions immediately produced the desired effect and also ameliorated other symptoms. Dr. Kinnicutt would at present prefer to use one of the new antipyretics, especially antipyrin, for they produced all the good effects of cold without any of its unpleasant ones. In one case, in which the temperature rose to 107° F., and there was every indication of approaching death, rectal injections of antipyrin produced most marked beneficial results, and the patient finally recovered.

The Society went into executive session.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting May 27, 1885.

John A. Wyeth, M.D., President, in the Chair.

Dr. R. W. Wilcox presented specimens of

MULTILOCULAR CYSTOMA OF THE RIGHT OVARY WITH HYDROSALPINX, ALSO CYSTIC DEGENERATION OF THE LEFT OVARY WITH SIMPLE SALPINGITIS.

The patient was thirty-seven years old, married, never pregnant. For the last fifteen years she had noticed an enlargement of the abdomen; for the last two years her size made locomotion very difficult. Her physician during all this time had considered it to be a case of abdominal dropsy, and of late had been prescribing diuretics. His attention had been called to the fact that an ovarian tumor was present, but he denied its existence, and stated, even if there were one, his medicines would speedily produce absorption. The patient came under observation in February of this year, suffering from two distinct diseases: a peritonitis extending over the epigastric, right and left hypochondriac and right lumbar region, also an acute nephritis, due to the excessive administration of diuretics. As for the tumor, there was no difficulty whatever in diagnosis; it hardly seemed possible that it could have been overlooked by anyone possessing medical knowledge. The diuretics being withdrawn, the nephritis subsided; the peritonitis resulted in adhesions between the tumor and the abdominal wall.

Dr. T. G. Thomas performed ovariotomy and removed

the specimens shown. The larger one consists of the sac, from which the fluid has been removed. The weight of the tumor was 45¾ lbs.; the sac weighs a little over 3 lbs. The fluid was of the ordinary "flax-seed tea" variety, containing considerable diffused blood and a great number of cholesterine crystals. The secondary cysts are mostly small, and contain clear fluid. Over the anterior surface is seen the roughened area marking the site of the adhesions. The Fallopian tube is elongated and hypertrophied, the distal extremity adherent to the tumor; the lumen at the uterine end is occluded. The tube was distended with a clear yellow fluid.

The smaller specimen is the left ovary and tube. The ovary has undergone cystic degeneration, some of the cysts being deep in the substance of the organ, and there seems to be more than the usual amount of fibrous tissue. There are also seen bands of adhesion between the tube and ovary. In the fresh state it showed most beautifully a *corpus luteum* of menstruation, which occurred about ten days before the operation. The tube was very hyperæmic and slightly distended with a clear fluid.

EPITHELIOMA OF THE TONGUE.

Dr. C. W. Knight presented a specimen which he removed at the Manhattan Eye and Ear Hospital after ligation of the lingual artery. It consisted of a portion of the posterior part of the tongue of a patient sixty years of age, who had had symptoms for more than nine months, but did not suspect the nature of the trouble until about two months later. During the last four months the patient had suffered from severe pain, which extended into the ear, but during the last few weeks he had been made comparatively comfortable by the local use of cocaine. The specimen was referred to the Committee on Microscopy.

LIPOMA OF THE BACK.

Dr. L. Waldstein presented a lipoma which was chiefly interesting from the fact that it was removed from the back of a woman eighty-six years of age, and showed the degenerative process which might or might not be attributed to a general atheromatous condition of the arteries. The operation was performed by Dr. Lange because of an ulcer of the skin which would not heal and gave rise to pain and other disagreeable symptoms. The wound healed by first intention. The patient was extremely emaciated, and in this there was illustrated the fact that those in whom emaciation goes to a high degree lipomas develop and do not appreciably diminish in size.

Dr. Waldstein called attention especially to the peculiar degeneration of a part of the tumor, in which there was evidently a formation of new connective tissue, with which could be seen small foci, larger ones in other places, and in some instances they had assumed the character of cysts containing putty-like material which had been proved to be a peculiar form of fat, the melting-point of which was higher than that of ordinary adipose tissue.

Dr. Waldstein also presented a specimen of

ADENO-CARCINOMA OF THE STOMACH.

It was of the form not found very frequently; of the diffuse variety, where the greater part of the new formation was not found in the pylorus, which was patent, but existed as a fungoid mass in the mucous membrane toward the cardia and fundus. The patient was a man forty-six years of age, who had suffered extremely until within the last three or four months. Previous to that time the symptoms were of an indefinite, obscure nature. The carcinomatous tissue had evidently grown very rapidly, as was demonstrated by the great quantity and also by the karyokinetic cell division. There were also found great quantities of small bodies which might have been mistaken for micro-organisms. Dr. Waldstein directed attention to this point for the reason that this granular detritus from division of the nuclei had in some instances been mistaken for micro-organisms. The case was specially interesting because near the edge of the carcinomatous mass could be seen small foci of the disease just beginning to develop. Microscopically it had the distinctive character of adeno-carcinoma, which is extremely malignant.

There was also extreme jaundice, and at the junction of the lower border of the ribs with the right mammary line was a tumor about the size of a pigeon's egg, which was mistaken for carcinoma of the liver, and which on autopsy proved to be an enlarged bladder caused by metastatic tumors of the lomphatic glands in the porta hepatis pressing against the bile-ducts, but not sufficiently to cause complete obstruction, as there was bile coloring-matter present in the duodenum, and also bile coloring-matter was found in the fecal discharges during life.

DIPHTHERIA—LARYNGEAL STENOSIS—CONGESTION OF THE LUNGS.

Dr. Joseph E. Winters, by invitation, presented a specimen consisting of the lungs removed from a child one year and eight months old, in whom the first symptoms of illness appeared on a Sunday, when it had a convulsion. The patient was not seen by a physician, nor did it have treatment of any kind, until the Friday following, when the child was brought to the Demilt Dispensary, where Dr. Winters made an examination and found that it had extensive diphtheria, involving all the faucial surface pillars of the soft palate, the tonsils, and a considerable portion of the posterior wall of the pharynx. The exudate was very thick and very tough. The child was kept in bed and was put upon the usual treatment, and went along very well until the following Wednesday. On Wednesday night there was a wake in the house, and during that night and the following day the child was very much neglected. On Thursday night the child began to have a little croupy cough, and on Friday for the first time the diagnosis of pseudo-membranous laryngitis was made, and was based entirely upon the character of the cough. There was no interference with respiration, the breathing was quiet, and the child was not apparently very ill. On Saturday and Sunday the child was very comfortable. On Sunday night serious interference with respiration developed, and tracheotomy was thought of, but was not performed because the father of the child objected. On Monday again the child was very comfortable; breathing was easy, and there was no obstruction apparently to respiration. On Monday night symptoms of obstruction to respiration again came on and continued from 10.30 P.M. to 2 A.M. Tuesday morning, when the child died from exhaustion and asphyxia.

The condition of the parts was somewhat influenced by treatment probably, as the child took large quantities of ipecac and tartar emetic, and there was a good deal of vomiting.

At the autopsy the lungs filled the thorax well. There was a little exudation upon the tonsils. The upper portion of the larynx was nearly free from disease, and very little of pseudo-membrane was encountered until they reached below the vocal chords, and from there, for a distance of three-fourths of an inch along the trachea, there was a good deal of exudation, and below that point muco-pus and vascularization were distinct, but no recognizable pseudo-membrane. The anterior surface of the lungs was somewhat more distended than usual, and apparently the air-cells were more distinct than they were usually seen. On the posterior surface the bases and the roots of the lungs were congested. On section muco-pus flowed from all, even the smallest, bronchi. At the bases of the lungs there still existed an unusual vascularity. In the anterior portion there was some anæmia with unusual distention. Sections had been made from the lungs, but there had not yet been time for a microscopic examination.

Dr. C. C. Lee asked Dr. Winters concerning his ex-

perience in the use of Dr. Joseph L. Dwyer's laryngeal tube.

Dr. Winters said that he had had no experience in the use of the tube; since it had been discarded so completely by French surgeons he had not endeavored to employ it.

Dr. Lee remarked that that was just as to the tubes used in Paris, but not quite just to the tubes used in this city, where they had arrested the progress of the spasmodic disease to such an extent, after other measures had failed, that lives had been saved which he thought would have been sacrificed had laryngotomy been performed. He could not say that by treating diphtheritic laryngitis life had been saved, but he thought such tubes were useful, and might with very great propriety be employed in such cases as Dr. Winters had mentioned, where objections, such as could not be overcome, had been raised to the performance of tracheotomy.

Dr. Winters said he was not at all familiar with the treatment adopted by Dr. Dwyer, and had not seen Dr. Dwyer's tube; but he had supposed that its use had been limited to laryngeal complication, occurring in measles, and had not heard of its being used in laryngeal diphtheria.

Dr. Northrup said that, in the New York Foundling Asylum, where urgent laryngeal symptoms had been present the tube had relieved them almost immediately, and that after death membrane was found to extend from the epiglottis to the finest bronchi. Of course, it was hopeless to attempt to cure such cases by relieving laryngeal dyspnœa, but the tube had thus far met the indications promptly and completely.

Dr. Lee said he did not raise the question on the supposition that the use of the tube in diphtheritic laryngitis would be curative, although there had been notice in print of its use in two or three cases, which were believed to be croupous laryngitis.

Dr. Northrup asked Dr. Winters if, in his experience during the past season, the pseudo-membrane had manifested a marked tendency to spread downward into the bronchi.

Dr. Winters said it had not been his experience. The cases of croup which he had seen had been mostly in consultation, and, according to his experience in diphtheritic croup, in the cases which were treated early the membrane did not extend very far below the larynx. He thought that by proper care, instituted very early in practice outside of public institutions, the spread of the exudation and formation of pseudo-membrane to very much distance below the larynx could be, as a rule, prevented. He thought that the character of the exudation itself would be modified, and its tendency to spread would be greater in foundling asylums than it would be in outside practice.

Dr. Boldt said that his experience had been the same in private practice as that which Dr. Northrup had seen in hospital practice—namely, that in the majority of cases diphtheria had, during the past season, manifested a tendency to spread into the bronchial tubes. Furthermore, where tracheotomy had been performed this winter the cases had proved invariably fatal, and in autopsies which he had made, in eight cases after tracheotomy, there was seen in each one membrane extending into the bronchi. He did not believe that the extension of the membrane could be prevented in every case, but probably a good deal could be done to restrain its progress somewhat.

Dr. J. C. Peters had seen false membrane upon the top of the larynx without extension downward, and the patient recovered with frequent irrigation of the throat and the use of bichloride of mercury dry upon the tongue, where it comes in contact with the pharynx and top of the larynx.

(To be continued.)

Compressed Tablets of Vaccini Lymph are manufactured and successfully used in Switzerland.

Correspondence.

AN UNPLEASANT ACCOMPLISHMENT.

To the Editor of The Medical Record.

Sir: I have encountered a phenomenon here which seems worth recording. There resides here a young man twenty-eight years old, who represents a large Eastern clothing house, and who does an extensive business for his firm by taking orders for men's suits, for which he makes the necessary measurements. He possesses the singular power of making many of his customers quite sick during the process of measuring. He proceeds very carefully and deliberately, with a painstaking that insures ultimate satisfaction to his patrons.

Quite early in the process it is not uncommon for the customer to become very sick, so that he has to lie down and then evinces the signs of extreme prostration and faintness.

In perhaps twenty-five per cent. of the cases complete syncope occurs. The young man says that he has probably "floored" fully one hundred persons in the last two or three years, some of them being large and wholly robust. The trouble occurs early in the measurement and generally while he is adjusting rule and tape to neck, shoulders, and arms, especially when one arm is extended horizontally, and one of his hands is at the customer's neck, and the other at the wrist. It has commonly occurred to persons who knew nothing about his rather annoying accomplishment, and hence were not in expectant mood, and always long before the subject could have become fatigued.

He also says that these peculiar events come in waves; he may go a month or more without discommoding a single patron, and then have a series of cases in a few days. Recently he "floored" three men in succession within an hour, without their knowing of each other's condition. He says that he is conscious of some unusual state of his nervous system at such times, and feels a tingling much as if an electric current were passing through his arms.

He attributes this unpleasant influence over his customers to electric action, and it may be remarked here that he can at any time develop electricity in the familiar way—but with uncommon facility—by shuffling over the carpet, and administer brisk shocks to his friends. He is in vigorous health and well nourished, of only moderately nervous temperament, a good singer, and very earnest, zealous, and successful in his business.

I may add that he always seems to be standing behind the customer at the stage of measuring when the depressing influence is exerted.

Yours respectfully,

Francis H. Atkins, S.B., M.D.

Las Vegas, New Mexico,
June 12, 1885.

Transplantation of an Eye.—Homer's ox-eyed goddesses are in danger of becoming very commonplace mortals. Dr. Chilbert was recently called upon to enucleate the eye of a young girl, and, with a due regard to her beauty, secured a rabbit's eye, which he inserted into the empty orbit. He reported the case to the Académie de Médecine with the remark that "at the present writing all goes well." But he omitted to state whether the young lady could see with her rabbit's eye, or whether it was simply an improvement on the vitreous organ.

Honors to an American Physician.—Dr. D. B. McCarte, of this city, who has passed many years in China and Japan, was recently decorated by the Mikado of Japan in recognition of services performed by him in the cause of medical education in Tokio.

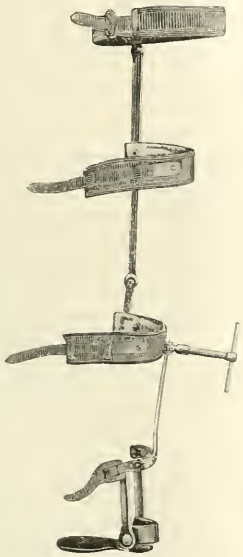
New Instruments.

AN APPLIANCE FOR THE CORRECTION OF INVERSION OF THE FOOT.

By THOMAS L. STEDMAN, M.D.,

ASSISTANT SURGEON TO THE NEW YORK ORTHOPÆDIC DISPENSARY AND HOSPITAL.

In certain cases of club-foot, after the varus deformity has been overcome there remains an inverted position of the member which is often a source of considerable annoyance and perplexity to the surgeon. This deformity is not due to weakness of the rotator muscles of the thigh, for the latter is usually rotated outward beyond the normal, through the patient's efforts to rectify the position of the foot. The inversion is located at the ankle, and the appliances commonly employed are inefficient, since they ignore this fact, and are so constructed as to increase the outward rotation at the hip. By their use the foot may be made to point anteriorly, indeed, but the knee is at the same time turned outward to such an extent that locomotion is rendered awkward, and almost impossible.



In the apparatus here figured I have endeavored to obviate this difficulty by applying the rotatory force so as to act upon the foot alone. The support consists of a simple external upright bar, jointed at the hip and knee, attached to a pelvic band above and provided with other bands encircling the thigh and the leg immediately below the knee. From the posterior portion of the lower band a rod with endless screw attachment passes down to the ankle-band of the scarpa shoe. In applying the brace the foot-plate is to be turned by means of the key until it corresponds exactly with the position of deformity. Then, after the heel is strapped firmly into the cup and a strong, well-fitting shoe applied, the key is turned so as to rotate the foot as far outward as may be desired. The normal position of the knee is not interfered with, although the foot may be slightly everted, and the patients are enabled at once to walk easily and almost gracefully.

107 WEST FIFTY-FOURTH STREET.

THE MICROBE OF ERYSIPELAS.—At a recent meeting of the Académie de Médecine, M. Cornil stated that a microbe is present in all forms of erysipelas. The organisms have been cultivated on gelatine by Fehleisen and Rosenbach. They are round, generally arranged in pairs, or in sinuous bands. The microbe of erysipelas is a streptococcus. Rosenbach asserts that there is a difference between the streptococcus of erysipelas and the pyogenic streptococcus. M. Cornil failed to observe any difference, but believes that, if the identity between the streptococcus of erysipelas and the streptococcus present in phlegmonous inflammation be not fully established, it is nevertheless demonstrated that erysipelas is always provoked by the presence of streptococci in the connective tissue, the plasma of the lymph, and the blood.—*British Medical Journal.*

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 12, 1885, to July 18, 1885.

VOLLUM, E. P., Lieutenant-Colonel and Surgeon. To be relieved from duty in Department of the East on the expiration of his present leave of absence, and to report to Commanding General Department of the Platte for assignment to duty as attending surgeon at the headquarters of that department. S. O. 159, A. G. O., July 14, 1885.

MIDDLETON, J. V. D., Major and Surgeon. Leave of absence extended fifteen days. S. O. 159, A. G. O., July 14, 1885.

BROWN, J. M., Major and Surgeon; EWEN, CLARENCE, Captain and Assistant Surgeon; TAYLOR, A. W., Captain and Assistant Surgeon; and BORDEN, W. C., First Lieutenant and Assistant Surgeon. Ordered to prepare for field service. S. O. 64, Department of the Platte, July 9, 1885.

GRAY, W. W., Captain and Assistant Surgeon. Relieved from duty at Fort Barrancas, Fla., and ordered for duty at Fort Columbus, N. Y. Harbor. S. O. 147, Department of the East, July 13, 1885.

EVERTS, EDWARD, First Lieutenant and Assistant Surgeon. Ordered for duty as Post Surgeon, Fort McDermott, Nev. S. O. 68, Department of California, July 11, 1885.

POLHEMUS, A. S., First Lieutenant and Assistant Surgeon. Ordered for duty as Post Surgeon, Benicia Barracks, California. S. O. 68, Department of California, July 11, 1885.

WINNE, C. K., Captain and Assistant Surgeon. Ordered for duty at Benicia Arsenal, California. S. O. 68, Department of California, July 11, 1885.

EDIE, G. L., First Lieutenant and Assistant Surgeon; BLACK, C. S., First Lieutenant and Assistant Surgeon. Ordered for duty with troops *en route* to Department of the Missouri. S. O. 78, Department of Texas, July 10, 1885.

Official List of Changes in the Medical Corps of the Navy for the week ending July 18, 1885.

OWENS, THOMAS, Assistant Surgeon. Granted sick leave for one month. July 14, 1885.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 18, 1885:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.

DEGENERATION FROM CITY LIFE.—Mr. James Cantlee, F.R.S., in a lecture before the Parkes Museum of Hygiene of London recently, presented a startling picture of the unfavorable influence of life in that great centre of population upon its inhabitants. *The Maryland*

Medical Journal, April 18, 1885, "cannot help thinking that he has very much overdrawn the picture, and that he has taken what is at best only of frequent occurrence among the lowest class of people as the prevalent condition of things. Yet he speaks very absolutely, and, coming from so high an authority, it is startling to reflect upon the wide range of application which his remarks may have, even reaching our American city population. The degenerating influences of city life—with its crowds, its dust, its vitiated atmosphere, its deprivation of sunshine and light, and want of healthful out-door exercise—cannot certainly be exaggerated, and the most intelligent efforts of sanitarians are needed to deal with the problems connected with these sources of physical degeneration. 'It is well-nigh impossible,' said Mr. Cantlee, 'to find a third, and absolutely impossible to find a fourth generation of pure Londoners—the progeny ceases partly from moral and partly from physical decline and inability of continuance.' The pure Londoner of the third generation, which he has been able, after much search and inquiry, to get hold of, is a picture of physical decline, involving shortness of stature, narrow chest, deformity of jaws, miserable appearance (squint prevailing), scrofulous diseases, and small head. Pure Londoners are seldom to be found in work-houses, because they die young. The only notion a Londoner has of relaxation is a run to the country or the seaside on a bank holiday. He foretold evil to the townsfolk of to-day if measures were not taken to provide means of exercise in fresh air. It is a serious question whether the welfare of this country shall in the next generation be left to a race out of whom all enthusiasm and earnestness has passed."

Epilepsy and Motor Functions of the Cortex.—M. Vulpian has recently shown, after having determined what is the minimum electric stimulus necessary to apply to the gray substance of the brain in order to provoke movements, that the same effects are obtained by a weaker current, if isolated electrodes (entirely covered by guttapercha, except at the extremity) be allowed to penetrate the gray substance until they reach the white matter. He also affirms that epileptic attacks are provoked by stimulating the underlying white bundles by weaker currents of less duration than those used for stimulating the surface of the gray substance. Other experiments by M. Vulpian tend to show that the gray cortical substance is of quite secondary importance in the pathogeny of epilepsy. M. Vulpian has arrived at this conclusion from freezing the cerebral surface of a dog by methyl-chloride, and then applying an electrical stimulus. M. Vulpian's views, if corroborated, will cause an important modification in the cortical theory of epilepsy.

Micro-organisms and Heat.—M. Charles Richet, at a recent meeting of the Société de Biologie, stated that heat helps the action of substances that impede or arrest the development of micro-organisms. In two bottles of urine mixed with a few drops of putrid urine, five milligrammes of mercuric chloride were added; one remained in the laboratory, the other was placed in a stove at 40° C. (104° F.). In the former, micro-organisms were developed; the other, which was subjected to heat, remained clear and limpid.—*British Medical Journal.*

The Latest Form of Hospital Construction.—The newest form of hospital design is the circular, which has attracted a good deal of attention of late, and designs of which were shown recently by Mr. Henry S. Burdett. Mr. Burdett states that the first advocate of the circular type of hospital wards appears to have been Dr. McKenna, a physician in Melbourne, in 1854, owing to his experience of the treatment of the wounded in the churches and chapels (which invariably took a circular form) of Spanish America, during the civil wars there. He noticed that the majority of the patients treated in the rectangular convent rooms died, while the large proportion of those placed in the circular churches adjoining survived. The plans of all the public circular hospitals which have been erected, or which are in course of erection, together with the latest example of a military hospital designed on the same principle, are now exhibited together for the first time. The advantages claimed for this type of hospital are: (*a*) its ready adaptability to the most confined site, (*b*) the more perfect aëration of the ward blocks, (*c*) freedom from stagnant corners internally, (*d*) the free admission of sunlight throughout the day, (*e*) increased superficial, floor, wall, and air space, and (*f*) a central system of heating and ventilation, which has an equal effect upon all points of the ward. Properly constructed, the distinctive advantages of the circular over the rectangular form of ward have been aptly shown by Professor John Marshall, F.R.S., the first advocate of this system in England, by comparing the circular ward to a tent. It has been found by experience that this form of construction is not, however, suitable for wards of less than ten beds, or possessing a smaller diameter than thirty-five feet.

Chloroform and Tape-worms.—Dr. N. O. D. Parks, of Ashton, R. I., after unsuccessfully using filix-mas, prescribed the following to a woman with tape-worm: He ordered her to fast for twenty-four hours, at the end of which she was to take one drachm of chloroform in an ounce of syrup in three doses, at intervals of two hours, to be followed in an hour by ol. ricini, two ounces. The prescription was completely successful.

A Compound Western Medical College—We take an opportunity, somewhat tardily, to give our readers the benefit of whatever justification may be found in the following letter from Irving J. Manatt, presumably Chancellor of the University of Nebraska. We would like to be more than just and say a kind word for the medical college herewith described. It appears, however, from evidence in our possession, that, unofficially at least, it has adopted unworthy methods in the solicitation of students. However, we will at least hope that it in time may shun eclecticism, etc., and become a creditable institution. Our correspondent writes: "My attention has been called to an editorial note in your issue of the 11th inst., of which note I enclose a copy herewith. As to matters of fact therein asserted, it is true that the University of Nebraska includes a College of Medicine; it is not true that this college 'has been taken possession of by eclectics.' From catalogues accompanying this you will observe that the medical faculty here consists of nine regular professors and three lecturers, with three special chairs of homœopathic and two of eclectic medicine. The college is not as yet materially supported by the State, having been organized by the Board of Regents in 1883, on an offer of gratuitous service by the faculty for a period of two years. It is believed that the college has justified its being and will be put upon a substantial basis at the coming session of the Legislature. As regards the *Nebraska Medical Journal*, it is in no sense the organ of the college, and is neither authorized nor patronized by the University. It is, so far as I can learn, purely and simply a private enterprise on the part of its editors, two of whom happen to hold the eclectic chairs in the college. As your note was calculated to give an injurious impression of the University, I trust you will do us the justice to make this correction."

Poliambulanza di Milano.—We have received the first annual report of the Milan Policlinic, for the year ending September 30, 1884. The institution was opened with three classes in May, 1882, but its organization was not completed until January, 1884. There are now eleven classes comprising all the recognized specialties, but not including general medicine and surgery. The number of patients received during the year was 12,179, of which 2,794 were in the orthopædic class, 2,380 in the ophthalmological, 1,010 in the otological, and 2,298 in the class of children's diseases. These figures would seem to indicate that the establishment of a dispensary of this sort was not uncalled for.

Original Articles.

INTRODUCTION TO A DISCUSSION ON THE DIAGNOSIS AND TREATMENT OF TUMORS OF THE BLADDER.[1]

BY REGINALD HARRISON, F.R.C.S.,

SURGEON TO THE LIVERPOOL ROYAL INFIRMARY AND LECTURER ON CLINICAL SURGERY IN THE VICTORIA UNIVERSITY.

AT the request of the Secretaries of this Section, I have undertaken the responsibility of opening a discussion on the diagnosis and treatment of tumors of the bladder.

Only a few years ago, anyone occupying this position would probably have felt bound to offer an apology to his audience for the scantiness of the material upon which he had to dilate; such, however, has been the progress of surgery within our recollection, that I feel myself differently circumstanced, and shall ask your indulgence in my attempt to compress the large amount of material which the experience of many has already supplied.

Time is more than precious on occasions such as these, and I must, therefore, avoid all historical references, deeply interesting and instructive as they are, and deal with my subject from a purely clinical point, feeling assured that this is the direction which will best answer our purpose to-day.

Under the guidance of the distinguished surgeon who presides over our Section, and in the presence of many who have made valuable contributions to this subject, I have the satisfaction of anticipating that the speakers who follow me will fill in the numerous gaps I must necessarily leave, and correct defects in my statement of which I am only too conscious.

I shall confine my remarks to tumors of the bladder proper, adopting where requisite the nomenclature set forth in the report of the Committee appointed by this Association, for the drawing up of which we are largely indebted to Mr. Paul.[2]

It is hardly necessary that I should occupy time with any remarks on the diagnosis of these growths other than those which will incidentally occur. Chief reliance will be placed on the circumstances under which blood appears in the urine, the manner in which the mechanism of micturition is interfered with, the presence or absence of evidences of new growth in the excretion, and the direct and indirect indications which may be afforded by the use of the sound or the catheter.

It will be convenient to arrange tumors of the bladder into two classes or stages: 1, Those which, during their entire existence, or for a portion of it, occasion either slight or no distinct indications of their presence; and 2, those which declare themselves by symptoms either seriously disturbing the function of micturition, or which by their constancy or degree threaten the life of the patient.

From the manner in which I have thus attempted in general terms to make use of a classification, it will be at once understood that individually I should be guided as to treatment, not by the fact alone that a patient has a growth in his bladder, but by the symptoms it produces.

The mere subjective evidence that a patient has a tumor of this kind would not, I submit, warrant the adoption of any operative measures to effect its removal, even if in addition it were possible to demonstrate its existence by other means than digital exploration. Some tumors of the bladder which have been found in the post-mortem room appear to have had no history connected with them, and instances are known in patients of the total disappearance, after varying intervals, of symptoms which were unmistakably those of villous growth or papilloma. Of the latter I believe that I am acquainted with more than one case. These are important facts, as they seem to indicate that what nature can accomplish, art may hope to imitate. How these growths thus disappear, whether it is by an accidental self-strangulation, or by an inflammatory act, it is impossible to say; but that they do so occasionally, without recurrence, I have not the least doubt.

Unfortunately, however, by far the larger proportion of them sooner or later pass out of the condition where operative interference is not to be recommended, and enter upon what I have taken as the second stage of their existence. Whether the transition is slow or rapid, gradual or sudden, much depends on their kind; but whether innocent or malignant, primary or secondary, the great majority of them, sooner or later, make it apparent that life will eventually be destroyed, either by persistent hemorrhage, or by the degree micturition is interfered with.

The question of operative interference will now be entertained; but before anything further can be said as to the hope of success which is likely to follow this, it is necessary that a more accurate knowledge of the connections of the growth should be obtained. This brings me to speak of digital exploration of the bladder.

If you will look at the two drawings which I show, you will see examples of two very opposite conditions; one where everything may be hoped for from operation, where complete recovery modern surgery has proved to be possible; and the other where nothing is to be expected except the relief of those symptoms of urgency which have rendered an opening into the bladder necessary. The first drawing represents a villous growth of three and a half years' duration, with a narrow pedicle, and is taken from Quain's "Clinical Lectures" (Plate xxiv.), which have recently been published; the second is an epithelioma extensively connected with the posterior wall of the bladder, from a specimen of my own in the Liverpool Museum.

Illustrations like these tend to show that though the diagnosis may be correct, the prognosis, so far as operative treatment is concerned, may fall very short of our desire, as the propriety of attempting to remove such growths can never be foretold until the finger has been placed in contact with them.

Digital exploration of the bladder relative to the treatment of tumors seems to me to be called for when it can fulfil at least three objects: 1, The relief of symptoms which are otherwise irremediable; 2, for verifying the diagnosis of tumor; 3, for determining whether the removal of the growth can be proceeded with. The circumstances which require a surgeon to open the bladder for the purpose of finding out what is inside it must be very exceptional; but when by this proceeding the three important objects I have mentioned are to be obtained with little risk, then its importance cannot well be overrated. There are recorded cases which seem to suggest that if the exploratory examination had been limited to

[1] Read before the Surgical Section of the British Medical Association at its Annual Meeting, 1885.

[2] British Medical Journal, January 12, 1884.

providing a means for draining the bladder, and for examining the growth, it would have been better.

In the case of an epithelioma of the bladder, such as you see in the illustration, which I have also taken from Quain (Plate xxix.), to attempt its extirpation is obviously out of the question; to explore it with the finger, and to feel so far satisfied, and at the same time to give the patient an opportunity of emptying his bladder completely by means of a short and open road so long as he lives, is legitimate; nay, further, experience has already sufficiently shown that there is no better way of controlling the considerable bleeding which nearly always attends these cases, than by providing the means of permanently maintaining the bladder in a condition of more or less contraction.

And now a few words in reference to the operation for exploring the bladder with the finger. If there are two ways to a place of about the same length but with somewhat different surroundings, you may depend upon it you will have two sets of travellers, with the same aims, but with very opposite notions as to the respective merits of the two routes. So with the bladder; though we are agreed as to the necessity of exploring it, we are not so unanimous about the route. In this country, as well as in America, median perineal urethrotomy seems to be preferred, whilst in France the claims of the suprapubic operation have been forcibly urged by Professor Guyon, Pousson, and others. Sir Henry Thompson has advocated the former method, not only as being the safest and most convenient for exploration, but, as he has shown by examples, for extirpating these growths. It seems to me that this form of procedure is to be preferred on several grounds.

In the first place, it provides a direct access to the more usual position of these growths; by a continuance of the incision forward into the membranous urethra and backward to the extreme limit of the prostate, it affords more room for manipulation than at first sight appears; but what is of more importance, it is, I believe, the best position for the drainage to follow, and which is a most important item in the management of these cases. If a perineal exploration shows the position or character of the tumor to be such as would be benefited by an access from the front, should it be determined to remove it, there is nothing to prevent the addition of the suprapubic incision, as Billroth demonstrated. A suprapubic incision is none the worse for having a more dependent opening, as Frère Côme practised a hundred years ago in connection with his success as an operator for stone. But, as I have already intimated, the great importance of the after-treatment, in relation to thorough drainage, renders, to my mind, the perineal procedure almost a necessity.

In connection with this point, it must not be forgotten what are the conditions under which these operations are often undertaken. In addition to the tumor which it is purposed to remove, there are usually present, either in the bladder itself, or in the organs associated with it, pathological changes which add considerably to the danger arising from the retention of anything which ought to escape. The viscus is occasionally sacculated, the ureters are patent and frequently largely distended, whilst the kidneys are rarely sound where the obstruction caused by the growths has been of long continuance. Hence we have much to fear from any extension of a suppurative process after the operation, as I have seen in two instances which have recently come under notice. One of the best safeguards against a contingency such as this, is thorough drainage, and this I think can best be secured through an opening in the perineum.

The feasibility of attempting to remove the tumor having been determined by digital exploration, the precise means of doing so has now to be considered.

It will not be necessary for me to describe at length how this has been effected after an opening has first been made into the bladder; in some instances the finger-nail has sufficed; in others, various kinds of forceps; quite recently, Mr. Pitts has recorded[1] a case where a growth was successfully removed by the *écraseur*. In examining two cases which terminated fatally, it appeared that if it had been possible to have applied a ligature round the pedicles, and then to have removed the growths cleanly, either with forceps or scissors, a different result might have followed. The nearest approach to such a proceeding seems to be one recorded by Mr. Henry Morris,[2] who, failing on the first attempt to remove a growth, in consequence of the want of the most appropriate means for extraction, the patient was left for two days, when the tumor was found prolapsed into the wound. Having stretched the edges of the wound apart by retractors, he succeeded in placing a ligature of catgut over the base of the growth and removing it with scissors. The patient made a good recovery.

When, after the bladder has been opened and explored, it seems practicable to remove the tumor, this should be effected as completely as possible; to take away a portion of it is to leave the remainder to inflame, suppurate, and possibly to become gangrenous, thus providing a fruitful cause for pyelitis, through the largely dilated ureters. Not being entirely satisfied with the forceps that hitherto have been used for the purpose of seizing and extracting these growths, I have had some others made for me by Messrs. Krohne & Sesemann, which, so far as I have been able to judge of them in practice, are well adapted for this object. It will be seen that they consist of an ordinary pair of bladder-forceps, with a free margin; by this contrivance it is almost impossible to do any damage to the wall of the bladder itself. The removal of the growth is effected partly by twisting slowly with the hand, and partly by the crushing action of the jaws of the instrument. In the exploration of the pedicle, both before and after removal of the growth, I have found one of Marion Sims' enucleator hooks exceedingly useful. If, however, the connections of the tumor are extensive, and there is a doubt as to whether all can be got away without doing serious damage to the bladder itself, I feel sure that we had better content ourselves with the opening, which may under all circumstances be safely made, and the drainage that this opening with a suitable apparatus will provide. The lesser proceeding has in many instances proved the means of arresting hemorrhage, and of adding materially to the comfort, as well as to the life of the patient, even where it has been found impossible either to remove the tumor, or with safety to reduce its size.

Time will not permit me to illustrate these remarks with cases from my own practice, where I have operated in accordance with the views expressed in this paper; these have already been noticed in a previous communication.[3]

I hope that Dr. Stein of New York, who has contributed importantly to the literature of this subject,[4] can tell us something to-day as to the general results following operative treatment, drawn from his most recent investigations upon this point.[5]

And what applies to the male is equally applicable to the female, though with the latter, by reason of the anatomical differences in the parts, both exploration and removal can be more readily effected. My friend, Dr. Alexander, of Liverpool, was, I believe, one of the first in this country to demonstrate the successful removal of growths from the bladder under these circumstances.

Of excision of portions of the bladder I have had no experience; so far as I am aware, it has been limited to some experiments on the lower animals, in furtherance of the subject which we have now under discussion.

In conclusion, it cannot be denied that operative surgery has already proved itself to be of considerable service

in the treatment of a very distressing class of disorders, and for which little is to be hoped for from medicinal agencies.

If I may be thought to have been too general in some of my remarks, permit me to say that this has been my intention; my object has been to open a discussion, and not to narrow it unnecessarily. The time has not arrived when it would be possible to lay down hard and fast lines of demarcation; much must be left to individual judgment. Where therapeutics are to end and surgery is to commence, experience and the application of those principles which are of general utility, and are not the exclusive property of any one set of organs, will enable us to determine what is best for each case as it presents itself to our notice.

ON FEEDING THE SICK.[1]

By WILLIAM ROBERTS, M.D., F.R.S.,

CONSULTING PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY.

My first duty is to express my acknowledgments to the Council of the Association, and to the South Wales and Monmouthshire Branch, for the honor they have done me in inviting me to deliver the address in therapeutics. This is, I believe, the first occasion in the history of the Association on which, from the wide domain of medicine, that portion which deals with the treatment of the sick has been specially selected as the theme of an address at the Annual Meeting. The subject of therapeutics is so large and complex that to deal with it comprehensively within the compass of an hour's address would be beyond my powers. Such an attempt, even in much abler hands than mine, could scarcely issue otherwise than in the enunciation of a series of barren generalities which would edify no one. I therefore felt, as soon as I came to consider the matter, that the most prudent course for me, and the one most likely to prove interesting to you, was to confine myself to a very limited area in the field of therapeutics, and to endeavor within that area to say something which might prove of use in the daily practice of your profession.

Perhaps of all the many duties which fall to the province of the medical practitioner, there is none so common as the duty of regulating the diet of his patients. Whatever the disease may be from which the patient is suffering, and whatever special means may be indicated for his relief, the regulation of the diet is sure, sooner or later, to crop up as an integral part of the management of the case. Dietetics, therefore, cover more ground than any other branch of the healing art—they are also, perhaps, the most ancient branch. Hippocrates traces back the very origin of medicine to dietetics. "For," he says, "the art of medicine would not have been invented at first, nor would it have been made a subject of investigation, if, when men are indisposed, the same food and other articles of regimen which they eat and drink when in good health were proper for them, and if no others were preferable to these." Notwithstanding this universal applicability, and this high antiquity, it must, I think, be allowed that dietetics, except in a few special cases, are somewhat neglected in these days. The often contradictory advice which is tendered to invalids in regard to their diet by the several medical men whom they may consult, betrays the want of a guiding principle and of a general consensus of opinion in the medical profession on the subject of feeding the sick. This is, perhaps, not to be wondered at when it is considered how little systematic study is devoted to dietetics, and how fragmentary is the instruction on this subject which is given to the student of medicine. So far as I know, there is no systematic teaching of dietetics, even on the most limited scale, afforded to the student at any of our medical schools. He is left to pick up his knowledge of this subject, as best he may, during the earlier years of his practice—and he often ends by taking his own digestive organs as his type, and prescribes for his patients according to the likings and dislikings of his own stomach. This is, I need hardly say, a very unsatisfactory proceeding; for there is, perhaps, no subject in which individual experience is so fallacious a guide as dietetics, and none in regard to which it is more important to draw our inductions from a wide basis of facts.

The first prerequisite for the acquisition of a sound knowledge of the dietetics of the sick is to have clear ideas on the origin and meaning of the dietetic customs of the healthy; for it is obvious that the proper diet for the sick must be some purposive modification of the diet of the healthy. We have, perhaps, been too much inclined to seek, or to seek too exclusively, in the physiology of digestion and nutrition, for our guiding principles and our point of departure in the study of dietetics. I doubt whether this is always, or even generally, the best starting-point. There are problems in human dietetics which appear to be beyond the reach of physiological research. What conceivable physiological inquiry, for example, could throw light on such problems as the following: What are the remote effects of the use or disuse of meat, or of alcoholic beverages, or of tea and coffee, on the bodily health and mental attributes of the individual and on those of his descendants in succeeding generations? And such questions are certainly, as I believe, involved in a comprehensive study of dietetics. On the side of natural history, it seems possible to approach such questions with some hope of success. For if we had the information, and could compare the mental and physical condition of the classes and nations which use these articles systematically, with that of the classes and nations which abstain from them, the elements of a solution would seem to offer themselves.

I venture, therefore, to say that the science of dietetics must be mainly based and built up on an observation and a study of the practices and customs of mankind in regard to their eating and drinking, rather than on any *à priori* data supplied by physiology. In the case of the lower animals, we assume that each creature selects, from the nutrient materials within its reach, those articles which are most suited to its well-being, and are best fitted to promote its success in the struggle for existence, and that it is guided in this selection by an almost unerring instinct. This, like other instincts, is now explained by biologists as consisting essentially in an inherited experience, which has been gradually accumulated through a long line of ancestors, and is transmitted by heredity to the descendants. Accordingly, when we see an animal feeding on a particular kind of food, we conclude without hesitation that that food is, of all the nutrient materials accessible to it, the best adapted for the special wants of its economy. But we know that man, in regard to his bodily functions, is subject to the same laws as govern the life of the lower animals; and we cannot doubt that in the formation of his dietetic habits man is guided by the same kind of instincts as those which guide the rest of the animal creation in the choice of their food.

The generalized food-customs of mankind are, therefore, not to be viewed as random practices adopted to please the palate, or to gratify an idle or vicious appetite. These customs must be regarded as the outcome of profound instincts, which correspond to important wants of the human economy. They are the fruit of a colossal experience accumulated by countless millions of men in successive generations. They have the same weight and significance as other kindred facts of natural history, and fitted to yield to observation and study lessons of the highest scientific and practical value.

In taking dietetic customs as objects of study it is obvious that widely disseminated customs, followed by many races and by vast masses of population, have a deeper

[1] Address in Therapeutics, read at the Annual Meeting of the British Medical Association, July 29th.

and broader significance than customs limited to a few races or to small communities. It is also obvious that the practices of the more successful races, and of the easier classes of a nation, are more likely to yield good dietetic models than the practices of backward races or of the poorer classes, because the former, owing to their ample means, have greater freedom of choice, and because also their greater success in the struggle for predominance is *primâ facie* evidence of the beneficial tendency of their food-habits. I need hardly say that dietetic customs which are not the outcome of the free choice of the population, but are the consequence of legislative enactments or of religious injunctions, are of no utility as guides in the study of dietetics—except, indeed, as warnings of the mischief that may accrue from ignorant meddling.

The British races and the other races of Western Europe, together with their kindred and descendants in different parts of the globe, are, on the grounds just stated, fitted to supply us with a body of dietetic customs which may be regarded as a beneficial model. These races and nations are every way, but especially in intellectual power, and in their productiveness of men of originality and eminence, far in advance of all others. Their food customs have grown up spontaneously, without material interference from legislator or religious reformer. Their world-wide commerce has brought cheaply to their doors the products of every land and every clime, and has enabled them to exercise a greater freedom of selection that has been possible to any other races.

The salient characteristics of the diet of the Western nations may be expressed in a few words. It consists partly of cereal and leguminous and other farinaceous articles, and of green vegetables and fruit, and partly of the various forms of animal flesh. The systematic use of alcoholic beverages is universal among them; and they consume, in large quantities, tea, coffee, or cocoa, or all three.

It is important to remark that the main dietetic customs of a country grow up and are established for the benefit of the robust and healthy, of the sober and temperate, and those of mean or average constitution—in other words, for those who are bearing the burden of the day, and fighting the battle of life. These form the great mass and bulk of the adult population, upon whose bodily and mental efficiency national progress and ascendancy depend. A good many individuals, and even entire families, may not find these customs, in certain particulars, beneficial to their exceptional tendencies or weaknesses; they may even find in them a source of destruction to their health and life; but here, as elsewhere, and indeed universally in Nature's operations, the individual is sacrificed to the welfare of the community.

> So careful of the type she seems,
> So careless of the single life.

Alongside the main dietetic habits formed for the operative mass of the community, there are secondary habits formed for the use of infants and children, and for persons advanced in years.

With regard to infants and children we observe that they are not allowed to partake of the accessory articles of food which form so conspicuous a part of the dietary of their elders. They are allowed neither the use of alcoholic beverages, nor of tea and coffee—except gradually as they draw toward adult age—but are fed on simple nutrients, milk, cooked cereals, and more or less meat.

With advancing years the diet undergoes a certain modification; the consumption of meat is, I think, somewhat lessened, and the consumption of soups, milk, and cooked cereals proportionally increased. With regard to alcohol, this modification of diet seems to vary with the preceding practice of the individual. Persons who have been in the habit during their prime of taking a full allowance of stimulants gradually diminish the proportion as age creeps on and their nutritive processes decline in elasticity and power. Sometimes the indications of this natural tendency are neglected or resisted by the unwary; they imagine that the quantity of stimulants they tolerated with impunity during the vigor of manhood cannot hurt them in later life. This is a serious mistake, the commission of which tends to accelerate senile decay, and to provoke fatally tending organic changes in the large organs of the body and in the arterial system. On the other hand, persons who during their youth and prime have only used alcohol occasionally, or have abstained entirely from it, find advantage in their declining years in a more systematic use of alcoholic beverages.

There is a clear difference also to be discerned in the dietetic habits of the two sexes. There are no available statistical data to go upon, but, from common observation, we cannot fail to note that men eat much more meat than women. Probably we should not err in estimating that two-thirds of the meat brought to market is eaten by men and only one-third by women. In regard to alcohol the contrast is still more marked. My impression is that, in this country, three-fourths, if not four-fifths, of the alcohol consumed is consumed by men, and only one-fourth or one-fifth by women. This difference is consonant with our experience as medical men that women are more sensitive to the effects of alcohol than men, and are more easily injured by the excessive use of it. On the other hand, the consumption of tea and coffee, but especially of tea, is markedly more abundant among women than men. The comparison is completed when we add that women consume, in proportion to the totality of their food, more milk and more bread than men do.

It would not appear to be a wise proceeding to depart capriciously and without clear reason from the general dietetic customs of the country. We may be quite sure that the use of meat, and of alcoholic beverages, and of tea and coffee, subserves some useful purposes to the human economy, though we, in our ignorance, may not be able to specify them with precision. These customs are the spontaneous outcrop of natural instincts and the fruit of an immense experience, and the sanction they derive therefrom constitutes an incomparably higher authority than the opinion of the wisest among us.

Nevertheless, differences of constitution and personal idiosyncrasies have to be reckoned with; and there are frequently solid, indeed paramount, reasons why individuals should, in some particular or other, depart from the general dietetic plan. I have known a few natural-born vegetarians who have had a life-long distaste for meat. Some persons are intolerant of tea, others are intolerant of coffee. It is, however, with respect to alcohol that the most important deviations from the mean type of constitution occur. Some persons are made uncomfortable by the most sparing use of alcoholic beverages, either through their life or at some epoch of it. A good many also are wanting in that self control which is necessary to the salutary use of this stimulant. These peculiarities or idiosyncracies must be attended to. It may be regarded as certain, as a very general rule at least, that any food or food-accessory the use of which is followed by a sense of discomfort is not beneficial to that individual. Persons who are unable to take alcohol in moderation should, on pain of loss of health and life, refrain from its use—for to them it is easier to abstain than to be abstemious.

These general considerations, as furnishing the natural groundwork of dietetics, should be kept steadily in mind in dealing with the practical questions which arise in feeding the sick. We may distinguish in a rough sort of way the patients who seek our aid in the matter of diet into two classes—namely, first, those who are able to take and to digest solid food and to conform in the main with the general dietetic habits of healthy people; and, secondly, those more seriously sick, who can take little or

no solid food, and must be fed on a plan deviating widely from the common custom.

The great majority of our patients belong to the former class, and are able to use the ordinary diet. They consist of invalids who are suffering from various ailments of the slighter sort, or from some more serious disease which does not interfere radically with the digestive functions. In regard to all these, I take it that (except in special cases, which I do not purpose to consider) it is a sound canon of practice to adhere to the main features of the current dietetic habits, and to avoid teasing our patients with irksome and needless restrictions for which we cannot give a clear reason. Diversity and variableness are marked characteristics of the dietary of the leading races of mankind—especially among the easier and more successful classes. The multifariousness of our eating and drinking is something very remarkable, and contrasts strongly with the monotonous fare of the less advanced races, and of the lower animals. Scarcely any two of our meals are exactly alike. Not only do the several daily meals—breakfast, dinner, etc., differ from each other, but the breakfast or dinner of one day usually differs more or less from the corresponding meal of another day. This variableness or diversity, we cannot doubt, fulfils some useful purpose beyond the mere gratification of the palate. It may, therefore, be inferred that to prescribe a monotonous regimen is to contravene a beneficial rule, and to depart from a salutary principle in human dietetics. We know that a healthy man soon rebels against a daily repetition of the same dishes, however wholesome and savoury; much more an invalid, with weak appetite and feeble enjoyment of his meals, who craves for more change and variety than the robust.

Another part of our duty is to study the peculiarities and idiosyncrasies of the invalid's stomach. Our stomachs are nearly as individual as our faces, and are very peremptory in regard to their likings and dislikings. In adapting diet to these idiosyncrasies it is, however, a good rule, as far as practicable, to lessen the quantity of the offending articles rather than to forbid them altogether; or, if they must be forbidden, to provide in their place substitutes of kindred nature. The practice of forbidding fresh vegetables and fruit is especially open to objection. These articles, in addition to their use in promoting the peristaltic action of the intestine, have important anti-scorbutic virtues; and although in these days, and among our own people, we almost never meet with fully developed scurvy, we are probably, without knowing it, often in the presence of incipient or larval scurvy. As there is a prearthritic stage of gout—a dietetic disease at the opposite pole of the feeding scale—so likewise, we may presume, there is a prehemorrhagic stage of scurvy. I have sometimes observed the existence of a low standard of health, without any very definite symptoms, which I could only attribute to a too protracted abstinence from fresh vegetables and fruit. I think it is possible to go too far in humoring a capricious stomach; and that, in persons of a hysterical or neurotic constitution, a too indulgent consideration for the ease of this organ may entail disadvantages in regard to the general nutrition of the body, and produce effects which in the long run tend to lower the level of health, and even to aggravate that gastric sensitiveness which we are seeking to abate.

I need hardly say that due mastication and cooking of the food are essential to easy digestion. Perfect cooking is especially important in regard to farinaceous articles and fresh vegetables. These are often imperfectly cooked and thereby rendered difficult of digestion by invalids. The bad reputation of potatoes and pastry in regard to digestibility is chiefly due to the fact that they are often imperfectly cooked.

A matter of considerable interest and importance is the regulation of the accessories which we use with our food. The chief of these are the various kinds of alcoholic beverages, and tea, coffee, and cocoa. These articles are usually taken with meals, and they mingle in the mouth and stomach with the food, and thereby directly complicate the task of the digestive organs. In the course of last year I subjected the effects of these accessories on salivary and peptic digestion to a somewhat extended experimental inquiry. The time at my disposal will not permit me to lay before you the details of these experiments; but as they will be shortly published I may ask you to take them for the present on trust, and to allow me to indicate some of the conclusions and practical lessons which appear to be derivable from the inquiry.

In studying the influence of our food-accessories on digestion, it is necessary to distinguish sharply between their action on the chemical processes, and their action on glandular and muscular activity. These two actions are quite distinct and generally opposed to each other; for, while all the food-accessories were found to exercise a more or less retarding influence on the speed of the chemical process, some, if not all of them, exercise a stimulating influence on the glands which secrete the digestive juices, and on the muscular contractions of the stomach. It is, also, necessary to distinguish between the effects of the food-accessories on salivary digestion and their effects on peptic digestion, inasmuch as wide divergencies were found to exist in this respect.

The distilled spirits—brandy, whiskey, and gin—were found to have but a trifling retarding effect on the digestive processes, whether salivary or peptic, in the proportions in which they are commonly used dietetically. Their obstructive effects only became apparent when used in quantities which approached intemperance. Taking this in conjunction with the stimulating action which they exercise on the glands which secrete the digestive juices, and on the muscular activity of the stomach, their effect in these moderate dietetic proportions must be regarded as distinctly promotive of digestion.

Wines and malt liquors exhibited an action differing considerably from that of ardent spirits. Wines were found to be highly inimical to *salivary* digestion. Even very small quantities of sherry, claret, hock, or champagne inhibited the action of saliva on starch to a very high degree. This is due to the considerable acidity which all wines possess. When this acidity was neutralized by the addition of an alkali, the inhibitory effect of wines on starch digestion was entirely removed. It is a common practice, as you know, to mix wines, especially sherry, claret, and hock, with soda, seltzer, or some other effervescent table-water. These waters all contain a charge of alkaline carbonate, and it was found that when wines were thus mixed they ceased to embarrass salivary action. This practice may, therefore, be looked on as highly commendable in the case of persons of weak digestion.

On *peptic* digestion wines exhibited a retarding effect altogether out of proportion to the alcohol contained in them. Both the stronger and the lighter wines, except in very moderate proportions, checked the speed of peptic digestion. In the customary dietetic use of wines with meals there is, probably, a double action—on the one hand, a stimulating action on the secretion of gastric juice and on the muscular contractions of the stomach, and, on the other hand, a retarding effect on the speed of the chemical process. In the case of persons of weak digestion, wines should be taken sparingly, and the quantity so adjusted as to bring out their stimulating action without provoking the retarding effects which follow their more liberal use. Champagne was found to have a distinctly less retarding power than an equal volume of claret or hock. This I judged to be solely due to the mechanical effects of the effervescence and liberation of gas, whereby a more efficient stirring up of the digesting mass would be effectuated. Effervescent wines therefore, other things being equal, favor the speed of peptic digestion more than still wines.

The effects of tea, coffee, and cocoa exhibited some interesting diversity. It was found that tea had an intense inhibitory effect on *salivary* digestion; even in very

minute proportion it completely paralyzed the action of saliva. On the other hand, coffee and cocoa had only a slight effect on salivary digestion. The inhibitory action of tea on saliva was found to be due to the large quantity of tannin contained in the tea-leaf. Some persons have supposed that by infusing tea for a very brief period—two or three minutes—the passage of tannin into the beverage could be avoided. This, however, is a delusion. Tannin is one of the most soluble substances known—it melts like sugar in hot water. One gentleman of my acquaintance, in his horror of tannin, was in the habit of preparing his tea by placing the dry leaves on a paper filter, and simply pouring on the boiling water. In this way he thought to evade the presence of tannin in his tea. But if you try the experiment, and allow the product, as it runs through the filter, to fall into a solution of perchloride of iron, you will find that an intense inky-black coloration is produced, showing that tannin has come through in abundance. You can no more have tea without tannin than you can have wine without alcohol; and I found, experimentally, that tea infused for two minutes had almost exactly the same inhibitory effect on digestion as tea infused for twenty or thirty minutes. If you wish to mitigate the effects of tea on salivary digestion, you should direct the patient not to sip the beverage with the meal, but to eat first and drink afterward. In this way time is given for the saliva to perform its functions unhindered. Another device is to introduce a pinch of carbonate of soda into the tea-pot: this removes the deterrent effect of tea on salivary digestion; it is a practice occasionally followed in some households under the idea that soda helps to extract the virtues of the tea-leaves. It was found that the addition of so small a proportion as one per cent. of the weight of the dry tea greatly mitigated its injurious effect on starch digestion, and that twice this quantity (two per cent.) almost entirely removed it. This latter proportion corresponds roughly to ten grains of bicarbonate of soda to an ounce of tea-leaf.

The effects of tea, coffee, and cocoa on *peptic* digestion were found to be as nearly as possible alike for infusions of equal strength. All three exercised a retarding effect when their proportion in the digesting mixture rose above twenty per cent. These beverages should therefore be taken very moderately by persons of weak digestion. The good reputation of cocoa in regard to digestion seems to be wholly due to the fact that it is used in weaker infusions than tea and coffee. The directions for the preparation of this beverage, printed on the packets of cocoa sold in the shops, indicate a strength of about two per cent.—whereas a medium tea is usually made of a strength of four to five per cent., and a medium coffee of a strength of five to seven per cent. The strong coffee which it is customary to hand round after dinner must have a powerful retarding effect on gastric digestion, and although this practice may be salutary to robust eaters, it is not to be recommended to those of feeble peptic power.

FEEDING THE SICK WITH LIQUID FOOD.

In a considerable number of conditions our patients are unable to take solid food, and are reduced to the necessity of using food which can be administered in the liquid form. This is usually the case in the febrile state and in serious organic disease, especially of the abdominal organs, and in the terminal stages of almost all diseases. There are other conditions in which, although the patient may have the ability to take solid food, it is not desirable that such food should be administered to him. In narrowing of the pylorus or other part of the digestive tract, in ulceration of the intestinal mucous membrane, it is obviously undesirable to administer articles of food which are capable of forming lumps or masses which may block up the narrowed parts of the intestinal tube or irritate the ulcerated surfaces. There is thus a large field for the employment of liquid food, and one of the most embarrassing tasks in clinical dietetics is to devise food in this form in sufficient change and variety, and having at the same time an adequate nutritive value. Our resources in this state of things consist of milk, beef-tea and other meat decoctions, cold-made meat infusions, raw eggs, and the various gruels. I propose to make some remarks on each of these articles.

Milk.—By far the most serviceable liquid food we possess is milk. Milk contains, in almost equal proportions, proteid, saccharine, and fatty matter, and is capable alone, as we know, of sustaining life. All plans of feeding the sick on liquid food centre round milk. It can be given alone, or mixed with tea, coffee, or cocoa, or with lime-water, soda-water, ardent spirits, or with farinaceous gruels of various sorts, or as buttermilk, koumiss, or whey. Were it not for the necessity of change and variety, we should, in a large number of cases, want nothing but milk. It should, however, be remembered, that milk is by no means a perfect kind of liquid food. In the course of its digestion, both in the stomach and in the intestine, milk, or rather the casein contained in it, is coagulated into solid masses, and these masses have to be redissolved before they can be absorbed. Not infrequently, if milk be given too freely, these curdy masses fail of being dissolved; and they pass down the intestine more or less unchanged, and are ultimately discharged with the stools. In this way milk may become an objectionable form of liquid food; these curds may block up a narrowed part of the intestine, or they may undergo putrefactive changes, and thereby irritate the tender or ulcerated mucous membrane. This drawback to the use of milk may be obviated by predigesting or peptonizing it, which is easily accomplished at a warm temperature by means of pancreatic extracts. The bitter flavor of peptonized milk is, however, nauseous to many invalids, and you cannot fully peptonize milk without developing this unpleasant flavor. One of the best means of covering the taste of peptonized milk is to add coffee to it. Another device, which may sometimes be adopted with advantage, is to add the pancreatic extract to cold or iced milk. In the cold the action of the ferment is comparatively slow, and it takes some hours to produce an appreciable change of flavor. But as soon as milk, thus charged with the ferment, is swallowed and passes into the warm atmosphere of the stomach, it is rapidly digested. I have seen, in cases of typhoid fever, when undigested curds of milk were observed to be coming away with the stools, this plan followed by the immediate disappearance of these masses from the motions. But the palates of invalids are sometimes abnormally sensitive, and they detect, and resent, the mere presence of the ordinary pancreatic preparations in articles of food, quite apart from the digestive changes produced by them. Recently Mr. Benger has placed at my disposal a pancreatic preparation which is absolutely free from taste and smell. This preparation, of which I have here a specimen, consists of the pancreatic enzymes in a highly-purified state, under the form of a light, nearly white, powder. It is not hygroscopic, and may be kept unchanged for an indefinite period fully exposed to the air.[1] This beautiful preparation is excessively active, and no palate can detect its presence in milk or other article of food until its effects are revealed in the process of digestion. I am inclined to think that it will prove a valuable addition to our resources when it is considered desirable to subject food to a process of predigestion, and still more when it is desired to add the ferment to the food in the cold state, with a view to promoting its rapid digestion after being swallowed.

Beef-tea and Other Meat Decoctions.—Next to milk in frequency of use and in high esteem come beef-tea and other meat decoctions. Long experience has satisfied us in this country of the usefulness of these preparations in feeding the sick. Beef-tea and its con-

[1] It slowly acquires a slight peculiar odor when kept in a tightly-corked bottle, but this passes off when it is exposed to the air.

geners, however, take rank as restoratives and stimulants rather than as nutrients. They contain no albuminous matter in solution, and the small quantity of gelatin contained in them cannot be of much account. There is a widespread misapprehension among the public in regard to the nutritive value of beef-tea. The notion prevails that the nourishing qualities of the meat pass into the decoction, and that the dry, hard remnant of meat-fibre which remains undissolved is exhausted of its nutritive properties, and this latter is often given to the cat or dog, or even, as I have known, thrown away as useless rubbish into the midden. A deplorable amount of waste arises from the prevalence of this erroneous notion in the households of many who can ill afford it. The proteid matter of meat is, as you know, quite insoluble in boiling water, or in water heated above 160° F. The ingredients that pass into solution are the sapid extractives and salines of the meat, and nothing more except some trifling amount of gelatin. The meat remnant, on the other hand, contains the real nutriment of the meat —and if this be beaten to a paste with a spoon, or pounded in a mortar, and duly flavored with salt and other condiments, it constitutes not only a highly nourishing and agreeable, but also an exceedingly digestible form of food.[1]

Cold-made Meat Infusions.—The defect in nutritious value of beef-tea led Liebig to suggest the use of cold-made meat infusions. He recommended that minced beef should be infused in cold water acidulated with a few drops of hydrochloric acid. An infusion so prepared differs essentially from beef-tea in the fact that it contains in solution a large amount of albuminoid matter. The addition of the acid is, according to my observations, a needless complication of the process. Infusions quite as rich in albumen were obtained when simple water was used as when the water was acidulated with hydrochloric acid. Infusions made from minced meat with half its weight of water, and allowed to stand for two hours, and then pressed through cloth, were found on analysis to contain over four per cent. of dry albumen. This amount of proteid is equivalent to that contained in cow's milk. The nutritive value of such infusions is, therefore, very high. When heated to the boiling-point they coagulate into a solid jelly. Made from beef or mutton, the product has an unpleasant bloody appearance; but when made from veal, the coloration is much paler. The best preparation, however, is made from the meat off the breast of a chicken. This meat is nearly white, and it yields an infusion which is almost colorless, and which sets, on heating, into a solid white jelly of very agreeable appearance. Cold-made meat infusions cannot be heated above 114° F. without becoming turbid from commencing coagulation of albumen. It is, therefore, impossible to cook them without destroying their liquid character. The objection to these infusions is their raw flavor, which to many is highly disagreeable—though some invalids take them without the slightest objection. The best way of covering the raw taste is to add some ordinary beef-tea or a little of Liebig's extract of meat. Some prefer a flavor communicated by a slice of lemon, or by the addition of a little claret.[2]

Beaten-up Eggs.—Another highly nutritive form of liquid food is supplied by raw eggs. The yolk, or white, or both together, are beaten up in various ways and combinations which are well known. Eggs are more easily digested by the stomach in the cooked than in the uncooked state; but when the stomach is weak and unable to digest solid food, beaten-up eggs pass through it into the duodenum without being meddled with, and are slowly digested in their passage down the intestine. They are incapable of forming lumps or masses, and are, therefore, well adapted for cases of narrowing or ulceration of any part of the digestive tract.

Fortified Gruels.—A very important kind of liquid food is furnished by gruels made with the several kinds of cereals or leguminous seeds. Gruels are not by themselves an agreeable kind of food; they lack flavor. But mixed with milk or beef-tea they constitute a valuable addition to our resources in feeding the seriously sick. When prepared from the cereal flours in the usual way they can only be made of feeble nutritive power—if their liquid character is to be preserved. These flours are very rich in starch, and gruels made from them become thick and pasty if the proportion of flour used in their preparation rise to four or five per cent., and a gruel of this strength does not contain more than one-half per cent. of proteid matter. But if the meal be mixed beforehand with one-eighth of its weight of ground malt you can prepare from these flours gruels of much higher nutritive value and still preserve their liquid character. The diastase of the malt acts upon the thickening starch as the heat rises and converts it into soluble starch and dextrine. These fortified gruels can be made with as much as twenty per cent. of meal and still maintain the fluid state. Such gruels contain about two per cent. of proteid matter, and about fourteen per cent. of carbo-hydrates, and are admirably adapted, combined with milk or beef-tea, to supply a varied kind of liquid food of highly nutritious character. Mixtures of this class seem especially suited for nourishment of cases of typhoid fever.

A matter of interest in designing food for the sick-room and nursery is the consideration of the special properties of the several kinds of cereal and leguminous substances used as food. In point of chemical composition the several kinds of cereal grains are closely allied. Still there are differences between them; and these differences may be of importance. The proteid of wheat is not quite identical with that of oats or barley. On the other hand, leguminous seeds differ importantly in composition from the cereal grains. Taking the lentil as a type of the leguminous group, it is to be observed that lentil flour contains twice as much proteid matter as wheat or oat flour, and almost twice as much lime. Moreover, the proteid of the leguminous seeds differs materially from that of wheat or oats. These differences are probably of not a little importance in feeding the sick and the young; and if we had more knowledge and experience in their use, we could perhaps utilize with advantage these several cereal and leguminous products, and combine them in varied ways to meet the indications and necessities of different cases.

You must all have observed how there has grown up in these latter years an enormous trade in prepared "foods" for infants and invalids. The very success of this trade is some evidence of the usefulness of these articles. Their composition is generally made more or less of a secret, but whatever secret there be must be hidden within a very narrow compass. The several possible flours out of which these "foods" are mingled can be easily counted —wheat, barley, oat, maize, pea, lentil, and one or two others. These are the ingredients—with malt flour in some cases—out of which they are all compounded. Now, I cannot help thinking that it would be an advantage both to ourselves and to our patients if we knew more precisely what we were about in this matter; and if we were in a position to prescribe for infants and invalids the several kinds of farinaceous aliments in proportions known to us, instead of blindly using some mixture of which we know not the exact composition. It is impossible for us to make progress in dietetics on such a path. I can quite believe that these flours have their special excellences, and that they are severally adapted for different cases and conditions. In the first place, they have distinctive flavors, and thereby may be made to contribute to the important end of providing change and variety for the invalid. Moreover, the faculty of "agreeing" of the

[1] These remarks on beef-tea apply equally to Liebig's Extract of Meat, Brand's Essence of Beef, and Valentine's Meat Juice—all of which are devoid of albuminous constituents.

[2] Cold-made meat infusions keep badly. They should be preserved in a cold cellar—or, still better, on ice.

different flours in reference to the individual idiosyncrasy is a point of not a little significance. Lastly, the difference of chemical composition between the cereal and leguminous flours must have an important bearing on the dietetic uses of these two groups of aliments. It is, I repeat, a serious disadvantage that the control of the preparation of food for the sick-room and nursery should pass from the hands of the medical attendant to those of the purveyor. In the matter of drug-giving, all enlightened practitioners are chary of prescribing secret remedies. Such a practice, it is felt, must be fatal to the intelligent use of drugs. So it is with providing food for the sick. What we want is to have at our disposal a supply of the several articles of food in their simple state, and suitable appliances in connection with the sick-room or nursery for cooking and combining them in various ways according to the exigences of our patients.

If I were asked to enumerate the ingredients and apparatus which are necessary for the cuisine of the sick-room and nursery, I think I could do so very briefly. In addition to the resources of the domestic kitchen and larder, the sick-room kitchen should contain a supply of the following flours: oat, maize, malt, and lentil flours in a finely pulverized condition and freed from bran. It should be provided with a solution of soda bicarbonate of known strength. This would be of use to add to milk when necessary, and to assist in the preparation of peptonized articles of food. Next to these would come a reliable pancreatic extract, and a preparation of pepsin or rennet for the production of whey. The associated apparatus should include a thermometer wherewith the nurse could, when desirable, heat up cold-made meat infusions to a proper temperature, and regulate the warmth required in the predigestion of food. A double-cased saucepan would form an indispensable item; this makes an admirable hot-water bath for the preparation of beef-tea and fortified gruels. A pair of scales, glass measures, and a mincing machine would complete the list. Finally, there should be, for the service of the nurse, a card or sheet containing plain directions for the preparation of the various kinds of liquid food.[1]

Given these simple appliances, I see no difficulty, in these days of skilled nursing, in the medical attendant being able to prescribe almost any kind of liquid food for his patients in any combination, and having it served up for the invalid in the most suitable possible manner. I have ascertained that there is no difficulty on the part of the miller in producing meals from malt, oats, or lentils, reed from bran and coarser particles, and in nearly as fine a state of preparation as wheaten flour. In this state these meals are susceptible of much more rapid and perfect cooking than when roughly ground. I have little sympathy with much that has been said of the advantages of whole meal and decorticated flour. It has been alleged that the too complete separation of the outer parts of the grain deprives the flour of its mineral matter. If we lived on bread alone there would be some force in this objection, but as that is not so, and as we find in milk, meat, fish, eggs, soups, and fresh vegetables a superabundant provision of mineral matter, and have, moreover, always at our elbows a supply of salt, there can never be any lack of saline materials in our food. The branny matter of the flour is both indigestible and irritating to the primæ viæ; and although it may not injure, or may even be useful, to the strong and healthy, it is quite an unfit element in food designed for the weak and tender membranes of the invalid and infant.

In bringing my remarks to a close I should like again to press for a more systematic and a more comprehensive study of dietetics. The effects of diet are profound and far-reaching, and exceedingly subtle. Some inkling of this is got from the history of gout. You all know how slowly and how insidiously the gout diathesis is developed under the influence of diet, and how it may affect the descendants into the third and fourth generations. The immediate effects of diet are often not the most important. Behind these are remote sequences of vital concern to the family and the nation. And it is not solely in regard to feeding the sick that a scientific knowledge of dietetics is useful. There are public questions of great moment, affecting the food-habits of the people, the consideration of which ought not to be dominated exclusively by popular opinion. In legislating on such questions it is of the last importance to proceed on correct lines; for it is certain that any policy which ignores the instincts of mankind and the laws of nature is foredoomed to failure. I believe that a comprehensive study of these questions from the side of history and of natural history would throw unexpected light on the issues involved, and furnish data of great value for the guidance of the legislator and social reformer.

[1] Messrs. Payne & Benger (Mottershead & Co., chemists, Manchester) have put together the ingredients and apparatus above enumerated in a portable box, of which a sample was exhibited at the Annual Museum.

ABSCESS OF BOTH FRONTAL SINUSES—OPERATION AND COMPLETE RECOVERY.[1]

By CHARLES STEDMAN BULL, M.D.,
LECTURER ON OPHTHALMOLOGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY.

The following case of abscess of both frontal sinuses and of the ethmoid bone is presented, not only on account of its comparative rarity and the extensive absorption of bone-tissue, but also on account of the long time which elapsed between the occurrence of the injury and the appearance of the permanent distention of the sinus, as well as the very rapid recovery.

Jane L——, aged fifty-three, widow, presented herself for treatment on October 27, 1884. Fourteen years before, while engaged in chopping wood, a piece of large size struck her on the bridge of the nose and median line of the forehead with such force as to knock her down. It made an ugly lacerated wound about three inches long, running from a point a little to the right of the median line of the forehead, and midway between the superior orbital margin and the hairy scalp, downward to the left, across the bridge of the nose, and ending just at the end of the left nasal bone, on the side of the nose. There was a fracture of both nasal bones, and a slight deviation of the septum to the right side. There was considerable swelling produced in the soft parts, the right eye was entirely closed by infiltration into the eyelids, and a rather profuse purulent discharge from the wound for several weeks. The wound itself did not close for about seven weeks. Since then the patient has at times suffered from a sense of distention or pressure over the eyes, which after lasting a few days would subside. Nothing unusual occurred until about four years ago, when the patient first noticed a somewhat hard, elastic swelling at the upper and inner angle of the right orbit, which at first could by pressure be caused to disappear, but which gradually increased in size, extended downward and along the superior orbital margin outward toward the temple, until the eye was entirely closed by the swelling and the complete ptosis. At somewhat long intervals there would be all the signs of an acute inflammation in the lid and neighboring tissues, accompanied by great pain, but these symptoms always subsided under the application of continuous heat. When I first saw the patient there was complete ptosis of the right upper lid, but without any infiltration. In the upper and inner angle of the orbit was an elastic, firm, resisting tumor, which could be traced some distance backward beneath the superior orbital margin into the orbit. The tissues along the orbital margin and over the glabella and bridge of the nose were very markedly thickened. The scar of the old injury was plainly visible. On lifting up the lid the eye was found to be pushed downward, outward, and forward, and to be almost completely immovable. Vision was reduced to $\frac{20}{70}$ in this eye, and was normal in the other eye.

[1] Read before the American Ophthalmological Society, New London, July 15, 1885.

A diagnosis was made of distention of the frontal sinus, and the patient was told that an operation must be performed in order to relieve her, to which she at once consented. On October 31, 1884, the patient was etherized, and a free incision, nearly two inches long, was made through the upper lid, just beneath the orbital arch, and parallel with it. As soon as the knife had cut through the skin and fascia, it entered a deep cavity and sunk out of sight up to the haft. A very large quantity of fetid pus at once poured out and covered everything in the vicinity, and as the wound was enlarged it continued to well up from the deeper parts, assisted by pressure with the finger in the orbit, and by turning the head of the patient upon the right side, until between two and three ounces of pus had been evacuated, as nearly as could be estimated. After all the pus had been removed the cavity was washed out with a five per cent. solution of carbolic acid, all of which came out again through the wound, none passing down into the nose. A careful examination was then made with the probe and finger, and it was found that the right frontal sinus was enormously distended; its floor had been corroded and worn away by pressure at the superior orbital arch, nothing remaining but a very much thinned periosteum. The bony partition between the two frontal sinuses had disappeared in part, so that the probe and the finger could be carried into the sinus of the opposite side. The carious and purulent degeneration had extended into the ethmoid bone, which in the course of years had become an immense abscess, and the plate forming the inner wall of the orbit had been in part worn away, so that nothing separated the pus-cavity in the ethmoid bone from the orbit except the periosteum. All attempts to discover the existence of any connection with the superior nasal meatus, by means of the probe and syringing, failed, but this examination revealed the presence of numerous osteophytes, mainly situated in the cavity of the ethmoid and left frontal sinus. As many of these as could be reached with the finger or forceps were broken off, and then the entire cavity was again carefully washed out with a solution of mercuric bichloride, one to two thousand. A small rubber drainage-tube, properly fenestrated, was then introduced, the external wound and neighboring parts carefully sponged with the above solution, and covered with several layers of iodoform gauze, and the patient placed on the right side. For the first week the cavity was washed out every three hours, but afterward this was done only twice a day, and subsequently only once a day. After a few days the drainage-tube was found not to act well, as it became clogged; it was therefore removed, and drainage was carried on by a few strands of long-fibred lint ravellings. There was a slight rise of temperature on the day after the operation, and considerable swelling of the lids and region of the eyebrow, but hot applications and frequent syringing of the cavity soon removed the symptoms, and from this time the filling of the cavity and the recovery of the patient was uninterrupted.

The patient was discharged on December 16, 1884, a little more than six weeks after the operation, with the wound entirely healed. The cavity had apparently filled from the bottom, and as it filled the infiltration in the soft parts gradually disappeared, so that when the edges of the wound healed the resulting cicatrix had already retreated somewhat beneath the orbital arch, and the patient began to regain some power over the levator palpebræ muscle. The patient was not seen again until February 2, 1885. At this date there was complete restoration of the position and action of the upper lid, and an entire disappearance of the scar beneath the superior orbital margin. All protrusion of the eye had subsided, and the motility was completely restored, but the eyeball was still on a plane somewhat lower than that of the opposite side. Vision had improved to $\frac{20}{40}$, and she had binocular single vision. The fundus of the eye showed nothing abnormal, except a slight discoloration of the temporal half of the right optic disc. The patient complained of a loss of sensation in the course of the supra-orbital nerve, but as this anæsthesia was limited in extent, and not very annoying, it was deemed unwise to attempt any operative interference for its improvement.

The pathogenesis of the case is somewhat obscure. The force of the blow was in the direction from below upward, and the first effect was probably a fracture or dislocation of the nasal bones at their line of union with the frontal bone, or possibly both. The violence of the injury to the bones, complicated by the extensive laceration of the soft parts, probably induced a periostitis, followed by a degenerative osteitis and caries of the nasal process of the frontal bone, which in time opened into the right frontal sinus and also extended through the thick bony septum in the median line into the frontal sinus of the opposite side. It is possible, also, that the caries extended along the floor of the right frontal sinus, in a line with the superior orbital margin, and in the course of years ended in complete degeneration and absorption of the bony partition between frontal sinus and edge of the orbit. All this time the process was extending backward, as well as laterally, into the cellular spaces and body of the ethmoid bone, and eventually the orbital plate of the ethmoid was perforated and in great part absorbed.

The patient was again seen on June 17th, and the recovery was found complete, with perfect restoration of motility of lid and eyeball, and a return of the eye to the normal plane.

THE SURGICAL AND PATHOLOGICAL ASPECTS OF GENERAL GRANT'S CASE.

By GEORGE F. SHRADY, A.M., M.D.,
NEW YORK.

No case has excited a greater interest from a medical point of vew than that of General Grant. Aside from the disease attacking a patient so widely known and so universally beloved, it has shown some features which are of surgical as well as of pathological significance. It is not the purpose of this article to treat of details of description or of treatment, as such will properly be left for elaboration by Dr. J. H. Douglas, whose constant attendance upon the patient best qualifies him for the performance of such a duty.

It is not definitely known when the throat trouble commenced, but probably it was early in June 1884, as at that time General Grant first complained of soreness in the right tonsillar region.

In October, after his return to New York from Long Branch, one of the lymphatic glands under the right angle of the lower jaw became enlarged, and he consulted his family physician, Dr. Fordyce Barker, who after satisfying himself as to the nature of the trouble referred him to Dr. J. H. Douglas for special treatment. The latter gentleman, also recognizing the serious nature of the malady, made the diagnosis of epithelial cancer, and commenced the use of palliative applications with the view of preventing the spread of the ulcerative process, then just commencing in the right posterior faucial pillar. For a time his endeavors were crowned with some success. Coincidently, however, with severe mental strain, occasioned by pecuniary embarrassment and attended with great physical prostration, it was noticed that early in December the disease took a fresh start and spread in upward and downward directions, so that in the course of the two months following, the posterior pillar of the fauces was almost entirely destroyed, the tonsillar space infiltrated, the base of the anterior pillar perforated, and the right side of the base of the tongue indurated and superficially ulcerated. This was the condition of affairs when, on February 19th, Drs. Barker and Douglas held a consultation with Drs. T. M. Markoe and H. B. Sands. The diagnosis of epithelioma was then unanimously confirmed and the judiciously conservative treatment of Drs. Barker and Douglas was fully endorsed.

On March 7th, when I first saw the patient, in consultation with Drs. Barker, Douglas, and Sands, it was found that the perforation at the base of the anterior pillar had extended so that its internal edge was converted into a mere bridle of tissue. The entire soft palate was uniformly reddened and swollen from inflammatory infiltration, and the surfaces of the right tonsillar region and adjoining portion of the vault of the pharynx were covered with a thick, consistent, yellowish exudation resembling sloughing tissue. This deposit was evidently the result of an acute process, engrafted upon the original disease, and partook in its clinical as well as physical features of many of the characters of a diphtheritic membrane. The enlarged and hardened gland under the angle of the jaw was then freely movable.

This view of the complication explains many of the grave symptoms which were subsequently associated with great prostration, but which were not directly traceable to the progress of the epitheliomatous degeneration.

Subsequent to this consultation visit an opportunity was offered the staff for examination of the microscopic specimens previously removed from the ulcerated edge of the posterior pillar of the fauces of the patient and prepared by Dr. George R. Elliott. I inspected the specimens in common with Drs. Barker, Douglas, and Sands, and agreed with them in expressing a due appreciation of the significance of the appearances presented. In other words, the microscopic examination showed the disease to be epithelioma. The appearances are correctly summarized by Dr. Elliott in his recent paper, and are properly judged by Dr. T. E. Satterthwaite. There was, in brief, a more or less lobulated appearance of the epithelial mass, with great diversity in the shape of cell elements—and marked evidences of epithelial proliferation; but, above all, there were present distinct cell-nests, and a tendency of the new cell-formation to burrow into the deeper parts of the underlying tissue. Extravasations of blood were also found in the diseased specimens.

The expediency of a radical surgical operation for the removal of the growth was discussed early in the case. It was considered that such a measure would have involved the division of the lower jaw in front of the ramus, the extirpation of the entire tongue and the greater part of the soft palate, together with the removal of the ulcerated and infiltrated fauces and the indurated glandular structures under the right angle of the lower jaw. This was considered mechanically possible, despite the close proximity and probable involvement of the tissues adjoining the large arteries and veins in the neighborhood of the ulcerations; but in the best interests of the distinguished patient the surgeons did not feel inclined to recommend the procedure. Even by such means there could be no guarantee, in view of extensive surrounding infiltration, that the limits of the disease could be reached without immediate risk to life by the severe shock to a constitution already much enfeebled.

From the time that the exudation appeared in the throat there was noticed for several days a marked depression of the vital power of the patient. Owing partly to the progress of the cancer and partly to the extra-inflammatory condition of the throat there was an increased accumulation of mucous secretion, the expectoration of which was attended with occasional attacks of choking. The latter of themselves had a tendency to exhaust the patient, and on more than one occasion alarmed his family and the public. The most serious attack of the kind occurred about 2 A.M. of March 30th. The General for a time lost his composure, and believed that he was about to suffocate. His distress was extreme. Dr. Douglas, who was summoned, called for me on his way to the patient. By the prompt syringing of the throat by Dr. Douglas the accumulated mucus was dislodged, when, as usual, immediate relief was obtained. The apprehension of a recurrence of the difficulty was so great on the part of the family, that we remained with the General until the afternoon, when another general consultation was held, attended by Drs. Barker, Douglas, Sands, and myself. The patient was found somewhat weaker, but was not considered in a dangerous condition. The area of exudation was increased, as well as the swelling of the palatal curtain, accounting for the extra difficulty of swallowing and a thickness of speech which were painfully perceptible. The pulse was inclined to be intermittent, and was decreased in volume, but there was no elevation of temperature. This weakened condition continued, despite the administration of heart-stimulants (digitalis and coca) and the careful regulation of liquid diet, until the early morning of April 1, when the patient was rather suddenly seized with an attack of fainting, and death from heart-failure seemed imminent. Dr. Douglas and myself were with him at the time. The members of the family were around the patient expecting that every moment would be his last. It was feared that he could not rally, and the farewells were said. Finally, hypodermic injections of brandy were administered, with the gratifying effect of tiding the patient over a threatened collapse. In the course of the next four hours he was considered out of immediate danger, and was able to take his liquid food.

The patient did comparatively well for the next few days, the swelling in the throat gradually diminishing, and the exudation showing a tendency to become separated. On April 7th, however, a hemorrhage from the throat occurred about midnight, which ceased spontaneously, after about four ounces of blood had been lost. The occasion for the bleeding was the detachment of a portion of the slough from the right side of the pharynx. No large vessel was implicated.

During the twenty-four hours succeeding the hemorrhage the pulse became more feeble, frequent, and intermittent, and the temperature at one time rose to 102° F. In order to relieve pain and procure sleep the patient was kept mildly under the influence of morphine, the latter being injected hypodermatically to the amount of six minims every six hours. The morphine was afterward decreased to six minims in the twenty-four hours, and but slightly exceeded that, save on one or two occasions, up to the day of his death.

The separation of the slough was anxiously awaited, and when it occurred the patient, as was expected, became much relieved of many of his more distressing local symptoms and of his depressed bodily condition. Then it was announced by the press that because the General had rallied, the physicians had erred in diagnosing the case, and consequently the patient's chances of recovery were good. Much as this happy result was to be hoped for, the stubborn fact of the existence of the original disease, and of its steady progress toward an inevitably fatal issue was painfully apparent to the gentlemen watching the case. The return of the patient's strength was not a surprise to his physicians. It was what they aimed to bring about by the treatment employed. The general exhaustion, which was in a great measure independent of the cancer, was at this time most feared, and the treatment of that condition was naturally of the first importance. But the gratifying change for the better was believed to be simply of a temporary character. Death, directly or indirectly due to the extension of the throat disease, was a question of a few months at most. The surfaces of the throat covered by the inflammatory deposit presented a clean appearance after the deposit was separated, but the primary cancerous ulcerations of the palate and tongue never changed for the better. The original disease was always there, slowly but surely progressing, resisting every treatment, defying every hope for cure, and grimly inviting the inevitable issue.

The temporary rally of the patient's strength was taken advantage of in every possible way to conserve his vital forces and make his last days as comfortable as possible. The success attending these efforts was manifested in many ways. He, however, possessed, in a remarkable degree, the faculty of repressing his feelings, bearing his

pain, and maintaining his mental composure, all of which was calculated to deceive a casual observer as to the real extent of his suffering. In the midst of this, and with a constant reminder of approaching death, he stoically gave himself up to the composition of his life-story, anxious only that he should live long enough to finish it.

The progress of the local disease was a steady one from the beginning. The ulcerations of the pillars of the fauces extended to the right side of the palatal curtain, almost destroying the latter and eating away the adjoining side of the uvula. The same process spreading to the region at the right side of the base of the tongue enlarged and deepened the ulcer there, destroyed the soft parts in the neighborhood, and burrowed its way downward beyond the reach of inspection or palpation. Toward the last the extent of the disease could only be estimated by examination with the finger in the throat, and even by that means its limit downward and backward could not be reached. The cavity at that point was irregular and deep, and was surrounded by a hard and ragged margin fading into surrounding indurated infiltration. The enlargement and hardening of the glands under and around the angle of the lower jaw continued to the last, when the superficial and deep structures of that side of the neck and face constituted a mass of cancerous disease solidly connected with the ulcers of the inside of the throat. At no time did the swelling outside threaten to break down into ulceration, but its size varied from time to time as the result of accidental inflammatory deposits. These increases in size were treated by warm applications, which quickly reduced the tumor to its original and fixed dimensions.

The loss of the palate and adjacent soft parts, with the consequent lack of perfect control of the tongue, occasioned great difficulty in swallowing. This was most painfully marked toward the end. His nourishment, which for six months was always in liquid form, was seldom taken without some choking. These paroxysms, however, became quite severe. It was only by his supreme self-control and calm determination to sustain his powers to the end that he was enabled to take his allotted quantity of food. He was compelled toward the last to hurriedly drink the entire contents of the tumbler without taking a breath. At the completion of the swallowing a choking fit would occur, which would result in a regurgitation of the last portion of the food through the mouth and nostrils. The latter difficulty was in a great measure overcome by following the suggestion of Dr. Douglas, not to attempt to swallow the last mouthful, and consequently at no time was strangulation threatened. During all his illness the breathing was not mechanically impeded by the extension of the disease into the larynx.

Just before he was transferred to Mount McGregor he rather suddenly lost his voice, never to regain it. This was due partly to thickening of the vocal cords by the inflammatory infiltration, and partly to a relaxation of the parts from general weakness.

A brief summary of the treatment is all that will be necessary to give now. Early in the disease, in order to eliminate every possible chance of error in diagnosis, the patient was placed under specific treatment, although the clinical history of the case gave only negative indications for its necessity. This treatment, although continued for a sufficient period, produced no effect in healing the ulcerations or in arresting the progress of the disease. Iodoform was used as a local application to the ulcers, as well as gargles composed of salt and water, diluted carbolic acid, solutions of permanganate of potash and yeast. A four per cent. solution of cocaine was occasionally applied to the painful parts with happy results, but it was never employed to any such excess as is generally believed by the public, nor were there any bad effects manifested from its administration at any time. The latter were carefully guarded against with the full knowledge that the drug was a new one, and that only its cautious use was admissible. Red-clover was given quite constantly, but produced no effect whatsoever upon the local disease. It only proved itself useful as a laxative and was so employed as being the least harmful of medicines of its sort for continuous administration.

His food consisted of beef-extracts, milk, eggs, and farinaceous materials, always in liquid form. In all detail matters bearing upon his food such appetite as he would occasionally manifest was the guide for any change. The rule was to deny him nothing he might crave.

During the last two days of his life he began to fail very perceptibly. On the evening of July 22d he signified his wish to be transferred to a bed. This was the first time he had left his easy-chair for purposes of rest or sleep since early in March. Dr. Sands and myself, who had been previously summoned at the final consultation, agreed with Dr. Douglas that the end was near, and that nothing more was to be done than to make the patient as comfortable as possible. The General had then lost his ability to swallow, his pulse was 120 per minute and feeble, and his respirations 25 per minute and shallow. His consciousness gradually left him at midnight. Continuing to sink, he died without a struggle at 8.08 A.M., Thursday, July 23, 1885.

Much to the regret of the entire staff, no autopsy was permitted. The family, gave as a reason for the refusal that each member was entirely satisfied with the diagnosis and treatment of the disease.

Thus ended a remarkable case. In commenting upon its features it must be conceded on behalf of scientific medicine, that everything possible in the present state of our knowledge was done to prolong life and make it as tolerable as the circumstances of the disease would admit. The diagnosis given early in the case was proved to be correct by the microscope, by the clinical history of the patient, and by the fatal issue. Appreciating the usual course of the disease, the staff at no time set any period for death until within the last twenty-four hours; nor did any member of it at any time during the patient's illness give the slightest reason for alarming the public by sensational rumors. As it is, the disease had a much shorter course than usual, owing to the prostration of the patient's system, dependent in a great measure upon other causes.

The cause of the disease in this case is largely conjectural. Epithelioma, as a rule, starts from local irritation, and, unlike other forms of cancer, is not dependent upon hereditary predisposition to the disease. There must, however, aside from this, be a latent tendency toward cancerous troubles which is more pronounced in some individuals than in others, otherwise we should be unable to explain why simple and continued irritation would induce the disease in one case and not in another. It is, however, quite probable that the irritation of smoking was the active cause of the cancer in General Grant's case, or, at least, it is fair to presume that he would not have had the disease if his habit had not been carried to excess. This assumption is made in the face of the fact that, of the thousands who smoke, but a very small proportion suffer from the disease.

As far as can be estimated, the cancer commenced only nine months before death. Fortunately the breathing was never affected by the involvement of the parts around the windpipe, nor was there any impediment to swallowing by the extension of the growth to the œsophagus. Both of these conditions might have obtained had the patient lived long enough to give an opportunity for the local disease to gain sufficient headway. The cancer presented an unusual feature in first invading the side of the throat rather than that of the tongue, as the latter is most frequently the original seat of this disease. The appearance in the throat of a sloughing process during the regular progress of the cancer was a circumstance worthy of note, and explained much of the exhaustion of the patient during one of his critical periods. If it had not been for this accidental complication the

epithelioma would have taken its usual course, and the public would not have mistaken the extension of the inflammatory process for that of the cancer, and would not have been ready to believe that the original disease was disappearing when the sloughy deposit was discharged. The patient at the time was better of the complication, but not of the cancer. The latter never changed but for the worse.

The occurrence of hemorrhage from the erosion of the walls of the larger vessels in the neighborhood was believed to be eventually possible, but was at no time seriously feared, as nature had thrown out her safeguards in the shape of dense deposits around the branches of the carotid artery and jugular veins.

Although there was more or less constant pain of a gnawing character, the patient was happily spared that agony of suffering which is often associated with the invasion of the deeper parts of the tongue by cancerous disease. Had the latter occurred, it was proposed to divide the sensitive nerve of the tongue (gustatory) through the mouth, which operation oftentimes gives absolute relief. Such pain as existed, however, was kept under control by cocaine and morphine, so that the last wish of the patient that his death should be a peaceful one was fully realized.

Clinical Department

ENORMOUS DOSES OF OPIUM IN PERITONITIS.

Dr. A. L. Haines sends the following interesting notes: May 4th I was called to see Norman W——, aged fourteen, who two days before had been subjected to severe atmospheric conditions.

Early history.—Four years before suffered with severe attack of acute articular rheumatism. Since, had no severe sickness; but unable to bear muscular exercise like most boys of same age.

Symptoms.—Complained of wandering pains in chest, arms, and limbs, especially in knee- and wrist-joints; also some in lower part of abdomen. Considerable nausea existed, and he had vomited several times. On examination, wrist- and knee-joints were found to be slightly swollen, and skin over them was red and glairy. Respirations were short and catching in character. Tongue was covered with a white coating. Temp., 100°. Pulse, 80—small, slightly hard, and irregular. A distinct purring thrill, with the other evidences of a mitral disease of the heart, was found on examination. There were considerable distention and tympanites over the hypogastric and right inguinal regions. This latter condition had escaped the attention of the attendants in the presence of the more active rheumatic symptoms.

The diagnosis of commencing peritonitis was made. The patient had been given a cathartic the day before, with the result of obtaining a few hard masses from the bowel. A hot flaxseed poultice was ordered over the bowels, and opii, gr. j., was given every three hours, and quinia sulph., gr. j., the same, except at 8 P.M. and 8 A.M., when he was given gr. v. of the same drug. In twenty-four hours I saw patient again. The tympanites and swelling over bowel had markedly increased. Pulse, 100, and temp., 101°. Vomiting had taken place several times. Patient had now assumed the characteristic position—on back with limbs flexed. These symptoms continued to increase in severity; and on the third day I saw him a very marked case of general peritonitis was to be seen. Poultices were now changed to Indian meal and hops, moistened in an alkaline solution of lye. These were made of generous size, and were covered with oiled silk and flannel. The doses of opium had been steadily increased, in order to keep patient narcotized, until they had grown unwieldy. Morphia sulph. was now substituted; gr. ss. of this drug was given, to commence with, every hour. As this was found insufficient, the dose was increased from time to time in order to keep patient completely under its influence. At the end of sixth day the patient was receiving gr. ij. to v. every half hour. This amount was scarcely sufficient to control patient. Having the case under immediate observation, I gave at one dose gr. v. of morphia and then repeated this dose in half an hour. The respirations came down to twelve per minute, and I was unable to arouse patient for two hours. Temperature at this time 103°, and pulse 110. When turning patient over to care of nurse, gr. ij. to v. was given every half hour, according as the respirations began to increase or decrease in frequency. From sixth to ninth day patient was in a critical condition; temp., 103°; pulse, 120, small and irregular. Tongue dry and brown; sordes on teeth; abdomen distended to the utmost. Patient continually sliding down in bed. Turpentine stupes were now employed along with poultice. Judicious stimulation with brandy was commenced from the very first sign of heart-failure. At the end of eighth day a slight softening was detected along direction of transverse colon, and from this time the tympanitic condition gradually subsided, and on the fourteenth day patient was convalescent. On ninth day there was a slight movement of bowels from natural causes.

The above case was interesting to the writer in many respects. But the most noticeable point was the toleration on part of patient of such large doses of morphia and so much of it. During the activity of the disease (first ten days) the patient received six one-eighth ounce bottles of morphia, and during the period of greatest activity (sixth and seventh day) he received one bottle of morphia, same size, in twelve hours. This large quantity of morphia could not have been needed to relieve the pain, nor could its object have been to produce a paralysis of the muscular coat of the bowels, as once taught, as that condition already existed. That this drug acted medicinally we have proof in its being so well tolerated.

The chief danger of this disease, and in fact of all serious inflammations, is the shock to the nerve-centres, and the consequent depression to the vital organs, especially the heart. Most cases of serious inflammations that result fatally do so because of this depression. These cases are of too rapid development to cause death from exhaustion. If death results it is generally before the tenth day. Almost every system, unless seriously undermined previously by disease, has vitality in reserve sufficient to carry them far beyond the period. Neither do these patients die from high temperature, as generally the temperature is not above 103°, and in the majority of cases it is below that degree. Death in most cases would seem to result from shock rather than from other causes. In counteracting this shock to the nerve-centres is to be seen the chief use of opium in this and allied affections. The danger of surgical operations from shock is greater, perhaps, than from any other cause. Take, for example, such operations as lithotrity, where death often results from this cause. In amputations death often results when there is scarcely any hemorrhage at all. It is a well-demonstrated fact that nearly all surgical operations are better borne when a full dose of opium is given.

The Cholera in Italy in 1884.—The Italian Government has just published an official report of the cholera epidemic of last year. Eight hundred and sixty-three communes, with a population of 5,771,000, or about one-fifth of the kingdom, were visited by the scourge; 25,587 cases were reported, 14,198 of which terminated fatally, a mortality of about sixty per cent. In Naples, with a population of 945,000, there were 15,927 cases and 7,968 deaths.

Progress of Medical Science.

Treatment of Neuralgia by Osmic Acid.—This subject was recently discussed at the meeting of the American Neurological Association. *The Lancet* of June 13, 1885, gives the following account of Dr. Schapiro's observations concerning the utility of osmic acid in inveterate neuralgia. The author's paper was read before the Medical Society of St. Petersburg. His observations include eight cases of trigeminal neuralgia (three males and five females). The age of the patients varied from thirty-eight to sixty. In every case the disease was of a very severe type and of long standing. The result of the treatment was complete cure in five cases (three females and two males), great alleviation of the pain in two cases, and no success at all in one case (female). The number of injections made in each was from one to twelve (twenty in one case), five to ten drops being injected every time. The duration of the treatment was from one to sixty days. Dr. Schapiro adopts a modification of Neuber's 1 per cent. aqueous osmic solution on account of the osmic acid soon undergoing decomposition in a watery solution. After a whole series of combinations, he concluded that an addition of glycerine to the watery solution prevents for a long time osmic acid from undergoing any change. In not one of the cases treated by him was an injection followed by any ill effect. The patients are now under the author's observation (two to six months after the commencement of the treatment).

Nephrectomy; its Indications and Contraindications.—Dr. S. W. Gross, in a paper in the July number of *The American Journal of the Medical Sciences*, based upon a study of nearly four hundred and fifty cases of different operations on the kidney, presents a careful analysis of all the facts pertaining to the surgery of this organ, and arrives at the following conclusions: 1. That lumbar nephrectomy is a safer operation than abdominal nephrectomy. 2. That primary extirpation of the kidney is indicated, first, in sarcoma of adult subjects; secondly, in benign neoplasms at any age; thirdly, in the early stage of tubercular disease; fourthly, in rupture of the ureter; and, lastly, in urethral fistula. 3. That nephrectomy should not be resorted to until after the failure of other measures, first, in subcutaneous laceration of the kidney; secondly, in protrusion of the kidney through a wound in the loin; thirdly, in recent wounds of the kidney or of the ureter, inflicted in the performance of ovariotomy, hysterectomy, or other operations; fourthly, in suppurative lesions; fifthly, in hydronephrosis and cysts; sixthly, in calculus of an otherwise healthy kidney; and, finally, in painful floating kidney. 4. That nephrectomy is absolutely contraindicated, first, in sarcoma of children; secondly, in carcinoma at any age, unless, perhaps, the disease can be diagnosticated and removed at an early stage; and, thirdly, in the advanced period of tubercular disease.

The Surgical Treatment of Cysts of the Pancreas.—In an article on the surgical treatment of cysts of the pancreas, Dr. N. Senn, of Milwaukee, in the July number of *The American Journal of the Medical Sciences*, presents a full report of a case of retention-cyst of that organ which has recently come under his observation, and, at the same time, summarizes, in a compact form, the clinical history of similar recorded cases, which serve as a basis for some general remarks. Of all abdominal organs the pancreas has been least frequently subjected to surgical treatment, for which its anatomical location, as well as the obscurity of its affections, furnish a sufficient satisfactory explanation. Situated high up in the abdominal cavity, and hidden behind such important organs as the stomach, omentum, and transverse colon, it is the least accessible of all abdominal organs, and on this account its affections, wrapped in obscurity, have for the most part constituted objects for empirical medication. The relation of this gland to the surrounding organs, and its great distance from the anterior wall of the abdomen, the only point of approach, necessarily offer serious obstacles to diagnosis and direct treatment. From a diagnostic point of view, another great difficulty is our want of positive knowledge concerning the physiological functions performed by this gland in the process of digestion. As the symptomatology of all affections of the pancreas is always obscure, and a probable diagnosis can only be made in cases where the gland has become considerably enlarged by disease, it is apparent that our present clinical knowledge is limited to diseases which increase the size of the organ to a sufficient extent to permit its detection by palpation. Primary malignant disease of the pancreas, when it has advanced to such an extent that its presence can be diagnosticated with certainty by physical signs, will have invaded the adjacent tissues to such a degree as to preclude the advisability of an operation; consequently the efforts by the surgeon, for the present at least, must be directed exclusively toward the recognition and treatment of benign affections of this gland. Clinical experience does not extend beyond an imperfect knowledge of cysts of the pancreas. The pancreas, like other secretory organs, is prone to become the seat of cystic tumors, the result of obliteration or obstruction of the common duct, or one or more of its branches. Cysts originating in this manner are true retention-cysts, containing the physiological secretion from the distal portion of the gland tissue, with perhaps accidental products, such as altered secretions, blood, and the products of inflammation. The author concludes his study of the subject by submitting the following propositions: 1. Cysts of the pancreas are true retention-cysts. 2. Cicatricial contraction or obliteration of the common duct or its branches and impacted calculi are the most frequent causes of cysts of the pancreas. 3. A positive diagnosis of a cyst of the pancreas is impossible; a probable diagnosis between it and some other kind of cysts amenable to the same surgical treatment is adequate for all practical purposes. 4. The formation of a pancreatic fistula under antiseptic precautions recommends itself as the safest and most expedient operation in the treatment of cysts of the pancreas.

Blisters in Head-Symptoms Produced by Cranial Lesions.—Dr. Handfield Jones records two instances of cerebral symptoms from long previous injury to the head. The first case was that of a man aged thirty-four, who received a cut on the right forehead sixteen years ago, and for the last two and a half years suffered from pain round the right eye and headache all over the head, which was generally brought on by exertion. He had frequent attacks of giddiness, and occasional fits of unconsciousness. The patient was under Dr. Jones' care for about two months, during which time ten blisters, at various intervals, were applied to the forehead, producing each time almost instant relief from pain for many hours, and sometimes days. The second case was that of a navvy, who received several wounds on the scalp through some bricks falling upon him. About two years after the accident he became subject to attacks of giddiness. In this case eighteen blisters (in all) were applied to the head, the result being a complete recovery from all his bad symptoms; and when he was seen by the author, fourteen years afterward, there had been no return of the attacks. —*London Medical Record*, June 15, 1885.

The Doctors of New York, says a second-hand Sixth Avenue book-dealer, are the only men who have the money, the taste, and the inclination to buy books. If there is anything good in the way of a book or a print they are sure to find it. The doctors are my best customers.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, August 1, 1885.

THE RELATION OF THE TARIFF TO MEDICAL WORK.

THE matter of the tariff and the relation it bears to his work seldom enters the mind of a physician.

It would seem that the first duty of a government would be to protect the health of every individual under its care. One would naturally suppose that one of the methods of attaining this method would be to educate the physicians of the nation to the uttermost. This apparently is the last thing the Government thinks of. Instead of encouraging such education by patronage and increasing the facilities, as is the case with some European governments, it throws obstacles in the way. The doctor must pay twenty-five per cent. duty on every foreign book that he purchases.

It is possible that if this tax were removed, that our American books would be less read; but it is hardly probable that the dust would accumulate more thickly upon them than it does now as they lie on publishers' tables and on library shelves. If the medical man gets broader ideas and wider views, as might happen, what would be the result? A better knowledge of how to treat his cases, how to restore his patient to a condition of health.

If a physician wishes European instruments, either because they are not made in this country, or if made, not of so good or useful material or form, he must pay, if metal or glass enters into their composition, forty-five per cent. duty; if soft rubber, twenty-five per cent.; if gum, thirty-five per cent.; if silk, fifty per cent., making the price from one-fourth to one-half as much again as they could be purchased for in the country in which they were made. Are these articles of luxury, without which one could easily accomplish the purpose? No, they are often instruments familiarity with which either improves the possessor's knowledge, or will increase his power of performing difficult operations successfully. It has been said so many times that it has become trite, but is nevertheless truthful, that the physician holds life and death in his hands. Should not, therefore, the Government, instead of demanding tribute and withholding thereby from those whose incomes are not abundant the means of perfecting themselves in their exacting calling, rather facilitate the procuration of books and instruments which, in reality, or according to individual opinion, will tend to this end.

The makers of medical and scientific instruments used in medical education are a small class in this country, and if their industry should suffer on account of the withdrawal of the protection which they now enjoy, their loss would be small in comparison to the great gain which might result to individual health and well-being because of doctors who, through imported ideas and instruments, have learned facts potent for good to their patients.

This is not a plea for foreign ideas rather than American, but for freedom for the physician to receive both on as nearly the same terms as possible, so that if there be anything in this country or out of it which will help suffering humanity, he may learn of it as speedily as possible, and at as little cost as possible.

It is ill becoming a Government which is supposed to have all the interests of its subjects at heart—and what interest is there greater than health?—for the sake of the small advancement to be obtained in commercial prosperity to cripple even in the smallest way the efforts of those which are exerted in this direction. We cannot but think that, coming in equal competition, instrument-makers would strive more than they do now to perfect their work, and the removal of the tariff for these things would be thus beneficial to the productions of the country.

It may be stated that colleges and hospitals can obtain instruments free of duty. It is so, but often with so much red tape and waste of time that the importers would prefer to pay the duty, as, indeed, an instrument-maker told us, they often did, than to endure the delay and vexation incidental to obtaining a permit. The law expressly states that no such instruments should be for the individual use of the physicians connected with the institutions. It is blindness which does not see that the advancement of the individual is the advancement of the whole, and that the need of Government patronage is as great for him as for the institution whose aim it is to educate these individuals.

In the matter of duty on drugs, on which there is an ever-varying tariff, possibly it is not such an injustice, if it forces the raising and preparing of them in this country in as good if not in a superior manner; but whatever interferes with the instruction of the physician in how to use these drugs to obtain the best possible results for his patient is to be greatly deplored, and will in the end prove a most short-sighted policy.

THE MEDICAL PROFESSION AND THE PALL MALL GAZETTE EXPOSURES.

THERE is one point in the recent exposures of London vice which seems to have attracted but little attention, and which we think ought not to be allowed to pass without a word of special condemnation. We refer to the part taken by certain medical men in granting the certificates of virginity, supposing, as one can hardly doubt, that these were genuine and not forged by the procuresses. There are, of course, rogues in every walk of life, but that men of a noble profession, whose aim is, or should be, to relieve misery and to advance the cause of humanity, should lend their names and thus give their sanction to such a horrible crime is almost incredible. One can hardly say which was the greatest villain, the retired physician who sacrificed annually between seventy and eighty virgins upon the altar of his lust, the procuress

who furnished the material for sacrifice, or the, presumably, impecunious practitioner who was willing, for a consideration, to certify to the fitness of the victims for the sacrifice. It is almost a pity that the matter was not taken into the courts so that the names of these brutes might be made known, and their bearers branded as unfit for association with decent men.

THE OLEOMARGARINE DECISION.

The reversal of the decision of the lower courts by the Court of Appeals in the recent oleomargarine suit, was not entirely unexpected, unless in the case of the officials of the Dairy Commissioner's office, but the decision seems to have put a temporary stop to efforts to destroy the traffic, and future efforts will have to be directed rather to discovering fraudulent sales of oleomargarine for real butter rather than to preventing all sales of the imitation.

The principle involved in the decision is one of great importance, and will have a far-reaching effect. It has been the theory on which many laws have been enacted in recent years to label a measure a health one, and that would enable the law to run the gauntlet of all the courts. The Tenement-house Cigar-law decision and now the oleomargarine decision show that a law must in reality be proven to be positively necessary for the prevention of health, or else individual rights cannot be overridden. In the case of the oleomargarine law it is very difficult to prove that pure oleomargarine is unhealthful, and the court held that to manufacture or sell such an article was not improper.

THE POVERTY OF DR. WARBURG.

Shall a physician keep secret his formulæ?

The answer to this question can be made promptly and emphatically in the negative. Whatever injustice may fall upon the individual, it would be demoralizing to the profession and injurious to the public if physicians attempted to make secrets of their favorite and most helpful formulæ.

We make this criticism as introductory to the case of Dr. Warburg which has just been brought up in the London medical papers. Dr. Warburg, who compounded Warburg's Tincture, is now a poverty-stricken old man. Professor W. C. Maclean, formerly of the Netley Army Medical School writes:

"Some years ago I appealed through the press on behalf of Dr. Warburg, to whom the people who serve in malarious climates are indebted for the most powerful febrifuge known to the medical profession, and which has saved many valuable lives. I have before me a letter from the lamented General Gordon, dated Khartoum, October 25, 1876, when Governor of the Soudan, addressed to Dr. Warburg, in which he says: 'I am (D. V.) coming home on leave (it would be for good were it not for your medicine, but I have such confidence in it that I look on returning with no dread), and will give you an order for £20 worth.' I urged Dr. Warburg to make its composition known. In compliance with this advice, Dr. Warburg came to Netley, and in the laboratory there made up a large quantity of his tincture, giving me at the same time his formula for publication, which I made known to the profession in the pages of *The Lancet* and *Medical Times*. I regret to say that this well-intended act of mine was followed by disastrous results to the inventor. It is now made and sold by druggists without any profit to Dr. Warburg, and I invite such of your readers who have derived benefit—perhaps had their lives saved—by this remedy to assist the man who has given to tropical medicine a powerful weapon to contend with a disease that kills twice as many victims as cholera and small-pox put together. The Government of India some time ago took the very unusual step of marking their sense of the value of Warburg's tincture by a grant of £200 to the discoverer. Dr. Warburg is now upward of eighty-one, and is in embarrassed circumstances."

The medical profession demanded of Dr. Warburg his secret; he gave it, and now the druggists make the money, and Dr. Warburg is left a poor man. It belongs to the medical profession to relieve the poverty which it has brought about.

SUPPLY AND DEMAND.

The demand for the degree of M.D. on the part of dentists has been met by the College of Physicians and Surgeons of Baltimore. This institution announces that graduates of the Baltimore College of Dental Surgery, who have also attended lectures on materia medica, anatomy, and oral surgery, will be entitled to graduate in medicine after attending one additional course of lectures on passing a successful examination.

This amalgamation of schools has another advantage—it swells the graduating list of the Baltimore College of Physicians and Surgeons.

We have heard that a dental school nearer home than Baltimore, or Hoboken even, gets the degree of M.D. in this way whenever any of its students feel the need of it.

THE BRITISH MEDICAL ASSOCIATION.

The meeting of the British Medical Association, which occurred this week and of which we present a cabled report, was a well-attended and interesting meeting. The character of the papers seems to have been so far largely clinical.

The most important event was, doubtless, the decision of the Association to erect a building for itself, at a total cost, probably, of over $150,000. Such a procedure will doubtless in the end prove economical, and will certainly add to the stability and power of the organization.

THE INTERNATIONAL MEDICAL CONGRESS.

The fact is unmistakable that the present organization of the International Congress seems gradually falling to pieces. Its best and most representative men have withdrawn. Opinions from the other side show that no confidence or sympathy will be felt in the position taken by the American Medical Association. It is useless to deny that unless something radical is done the Washington Congress will be simply a humiliation of American medicine before the world.

Is the Association willing to take the responsibility of bringing this about? We trust not, when, by a manly

and sensible acknowledgment of a mistake, the whole matter can be adjusted.

There is no quarrel between the East and West, nor do any but a few care for changes in the *personnel* of the present Executive Committee. We see no reason why, as has been urged, they should resign. Let them remove the medico-political issue and we can assure them that the whole profession will manfully stand by them in all other points.

News of the Week.

The International Medical Congress.—Perhaps, with the exception of one or two journals, the medical press, both in the United States and in England, has disapproved of the action of the American Medical Association in overthrowing the work of the original Committee on the Organization of the Congress. In fact, we are able to mention at this time but one prominent journal which has sustained the Association in its course, and this is the journal owned by the Association and conducted solely in its interest. The present outlook for the Congress admits of but one opinion, which is this, that the Association has committed a serious blunder and has shown itself incapable of reorganizing or conducting the Congress under its auspices. It seems clearly the duty of the Association to resign this matter into the hands of the general profession. The Association has so completely forfeited the confidence of the best minds in the profession, and has so antagonized the medical press of the country, that it seems a mistaken policy for it to attempt to proceed with the work of reorganization.—*Maryland Medical Journal.*

"The Washington Congress in Danger."—Under this title we copy the following from a leading editorial in the *Medical Times and Gazette* of London: "Those who have looked forward to taking part in the next International Medical Congress, and have counted perhaps on making personal experience of that friendliness and hospitality of which every English doctor who has yet crossed the Atlantic has brought back such golden report—yes, and not only those, but every practitioner to whom the reputation of his profession is dear, will have read with intense surprise, if not distress, the intelligence we published last week, that the Washington Congress is in imminent danger of falling through. We are sorry to announce that our worst anticipations are in process of realization. . . . We can only hope that the sound sense for which our American cousins are so distinguished will prevail, and that the decisive action of the Philadelphia practitioners will rouse the mass of the profession in America to step in, and to decide by overwhelming numbers before it is too late, that old controversies shall be sunk, that old ill-feeling shall be buried, and that no one shall be allowed to turn partisan spirit into a ladder for his own elevation at the expense of the reputation and good-fellowship of the profession to which he belongs. We do not wish, and we hope no one on this side the Atlantic will attempt, to revive the memories of the celebrated dispute on the Codes. We believe that the late Dr. Panum, the lamented President of the Copenhagen Congress, distinctly insisted, when the invitation to America was accepted, that the Code question should not be raised; and we feel sure that a very large majority of English and Continental practitioners will refuse to cross the water if this understanding is not rigidly kept to. They will feel, too, that if they go to Washington they can only go as the guests of an undivided profession. A Congress from which the most distinguished representatives of American medicine were excluded or had withdrawn, would not be worth going to as a scientific meeting, while the remembrance of the bitterness and heart-burnings which had attended its organization would rob its social distractions of all their charm. It would be like feasting with a man, while his wife, unjustly divorced, stood in the street watching. We can assure our American readers that in the present case the best English sympathies will be with the wife. The men whom English visitors, if they go, will go to see and hear, are the very men who have been elbowed out of the Congress. The scientific success of a Congress does not depend on numbers, but on quality. The profession in America is no doubt rich in numbers, as well as in scientific activity, but it is not so rich that it can afford to play all Europe with only pawns on its side of the board."

Navy News.—Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service for the two weeks ended July 25, 1885. Surgeon C. S. D. Fessenden, leave of absence extended eight days on account of sickness, July 20, 1885. Passed Assistant Surgeon Fairfax Irwin, granted leave of absence for ten days, July 14, 1885; to inspect unserviceable property at St. Louis, Mo., July 15, 1885.

Chloroform Poisoning.—Dr. Llewellyn Eliot, of Washington, D. C., writes concerning his paper on "Chloroform Poisoning": "In table, Case 2, 30 grs. should be 30 gms.; in table, Case 5, ℥ ivss. should be ℥ v. In abstracts, Case 49, one gramme should be gr. ij."

Professor J. W. Wright, M.D., of New York, has resigned as Professor of Clinical Surgery, University of Vermont.

Medical Education.—In a learned address, delivered at Albany before the University Convocation, July 9th, on Medical Education, Dr. William H. Watson asks: "What, then, should constitute the proper conditions of medical licensure in the State of New York? and answers: 1. A fairly liberal preliminary education. 2. Four years of professional study. 3. Examinations and license by an impartial court appointed by the State." In regard to the last point, Dr. Watson says: "A single paragraph of law would, by making the law of 1872 compulsory, convert it into a system as effective as the German Staats Examen, which, in the judgment of the speaker, is by far the most efficient system in the world. We firmly believe, therefore, that some modification of this law, made compulsory, will at no distant date revolutionize the system of medical education in the State, for the following reasons: First, it cannot, if made compulsory, fail to accomplish the object which all educated men so much desire—the elevation of the standard of medical education in this State. Second, while it confers no special or peculiar privileges upon a class, yet the degree will be an assurance to the public of the qual-

ifications of all who shall attain it, and will, therefore, be a legitimate passport to professional success. Third, the provisions of such a law will not in any way conflict with the vested rights and privileges of the medical colleges. It will, however, furnish an inducement to them to increase the thoroughness of their instruction, and to advance their standards of graduation, since in course of time that institution would attain the highest reputation from which the largest number of graduates should have obtained this degree. Finally, we believe that no other measure can be devised which would so powerfully tend to the advancement of sound practical knowledge among the future members of the medical profession, while its liberal, impartial, and entirely catholic provisions would leave no reasonable room for objection, and would eventually commend it to the good sense of the people of the State."

The Faith-cure for Cholera.—The correspondent of the *British Medical Journal* at Valencia, Spain, writes: "There have suddenly come into our city four 'apostles' of 'faith-healing,' who have gathered crowds around them. It is said that numbers have been healed of cholera. They are all poor men, receive neither money or gifts for their reward, only they accept a little food wherever they are at meal-time. They sleep in the fields at night, and beg to be allowed two hours out of the twenty-four for sleep and prayer. They belong to Andalusia and Jaen. They gently rub the abdomen, then place a jar of cold water on the mouth of the sick, exhorting them earnestly to put faith in God with all their mental or soul power, at the same time reading out from Scripture several passages; then they pray and breathe over them. It seems there are several of them scattered about. They never interfere with the medical man's duties."

Dr. Fehling, of Stuttgart, well-known for his invention of "Fehling's Solution" for testing for sugar, died on July 1st, in his seventy-third year.

Ferrán's Defence of Himself.—The *Progrès Medical* contains a full account of M. Brouardel's experiences in Spain with Ferrán, but adds nothing new to what we have published. The Paris correspondent of the *Philadelphia Medical Times* writes that Dr. Ferrán gave the following answer to the Commission: 1. That he refused to make known to them his process of attenuation of the virus of the cholera. 2. That he would allow them to examine his liquid in his *own* laboratory, but that he would not allow a drop of it to be taken away. 3. He proposed to the Commission that they would make a culture of the bacilli from the cholera-dejections and hand it to him, when he would attenuate it and return it to them. The Commission refused, and returned to France. It is only fair to give Dr. Ferrán's reasons. He writes a long letter to justify his views. He says: "I commence by declaring that in regard to the prophylaxis of cholera there are two points of view that are quite different. The first one is the effects produced by the vaccination. This is the one that really interests humanity; and the second one is the manner in which I make the attenuated liquid. This last is quite apart from the first. What interests all the world is, Do the inoculations practised with my method really prevent cholera? and I claim that they do. That the second part interests all the world I do not believe, and I have particular reasons for not giving up, at present, my secret. After having worked a long time at these studies I submitted my results to my Government, but I was received with a silence and an opposition that was trying. I received no help except from a few friends. I sacrificed all I had—my health, my practice, and what little resources I had—to find not the slightest assistance, even after I had proved the great importance of my discovery. I do not refuse to show my process to all the world if the Government will recompense me in some slight way for all my trouble, as the German Government did Dr. Koch. All the glory in the world cannot recompense me for the pain I should feel if I should leave my children in poverty."

Medical Women in India.—The association established at Bombay, about two years ago, for bringing out medical women from England, for the treatment of zenana females, have published their first annual report. It appears that over two hundred thousand rupees have been subscribed, a dispensary started, a hospital put under way, and that two medical women have already been at work, treating one hundred to three hundred patients daily.

The International Medical Congress.—The Cincinnati members of the organization, embracing leading members of the profession in that city, have formally withdrawn, as have also Professor E. S. Dunster and Dr. Henry Sewall, of Ann Arbor, Mich. In so doing they say: "In taking this step we do not intend to criticize the Committee for their action. On the contrary, we think that, handicapped as they were, they did their work remarkably well. But we do object to the action of the American Medical Association, at its New Orleans meeting, in introducing into the question of the organization of a congress for scientific work an element that has no more pertinency to such a purpose than the matter of a man's religion or his political views."

Intemperate Illinois Physicians.—We can hardly believe that the following item, vouched for by the *Journal of Inebriety*, is true. If it is, we must recommend St. John or the Salvation Army to our Illinois brethren. Says the *Journal* in question: "A Chicago physician sends us the following: The State Board of Health of Illinois reports the death of two hundred and two physicians. Six are attributed to suicide, five are recorded as coming from the accidental overdose of morphia, and two from an overdose of chloral. Over thirty of this number were known to use spirits to excess. He thinks that twenty-five per cent. of all physicians who die under forty may be classed as victims of alcohol or other narcotics."

A Medical Curiosity — Balfour's Disease, or Chloroma.—A disease of which only eleven cases have ever been observed must have interest purely as a curiosity. Chloroma was first described by Balfour in 1834. Since that time ten cases have been reported, and now an eleventh case has been observed by Gade in Christiania. The subject was, as is invariably the case, a child, a little girl of five years of age. The first symptoms

were deficiency of blood, a tumor of the left cheek, toothache, otorrhœa, singing in the ear, deafness, and exophthalmos, which gradually increased. Afterward fever and extreme prostration supervened, and she died in about two months. At the autopsy, numerous yellowish-green tumors of fibro-sarcomatous structure were found in many different parts of the body, more particularly on the periosteum. They were found also on the dura mater, in the liver, colon, lateral ligaments, and kidney, and even in the marrow of the long bones. On the legs a number of dark spots were seen, some of which contained a soft greasy substance. The origin of the greenish coloring-matter was thought by Otto, and Gade agrees with him, to be in the fat-granules, numbers of these being found in the cells, and so to be independent of both bile coloring-matter and hæmatin.

The General Verdict.—The International Medical Congress is becoming moribund.

Another Honor for Pasteur.—The Barotte prize of 3,400 francs, awarded to the inventor of the most important and useful invention for agriculture, has been awarded to M. Pasteur.

The Institute of Heredity and Hygiene of the Woman's Christian Temperance Union is the modest and unassuming title of a new society recently organized in the solid little State of Vermont. We are glad to see "Institutes" and other evidences of scientific progress, but we must give a caution to a society that starts off with such an intemperate length of name as the above. One must not think that because he read papers at an "institute" that he is therefore wise and scientific. The fact is such a name as the above suggests greatly a party of pseudo-scientific sentimentalists. Get rid of it, therefore, and prosper.

Not the Consultant.—Dr. A. Y. P. Garnett, of Washington, D. C., has taken the trouble to send us a discourteous note denying our conjectural statement that he was called in consultation with the homœopathic physician attending Mrs. Bayard. Having heard a rumor to the contrary, we take the opportunity now of begging Dr. Garnett's pardon for supposing that he would be called in consultation in this case.

Professor Van Ermengen, of Brussels, who went to Spain to study Ferrán's methods, makes a similar report to that of the French Commission.

The Difficulties of Becoming a Successful Physician.—The press of competition is so fierce in the present over-crowded state of the medical profession, that unless a man has some peculiar and decided advantage over the general run of his fellows, he stands no chance of coming to the front. Something more is necessary nowadays for success in the higher walks of medicine than mere general ability. Supreme talent will, of course, ultimately find its level, unless kept down by accident or misfortune; but for the average clever man there is little prospect of brilliant success unless he has (or can persuade the world he has) the power of doing some particular thing better than any one else, or at any rate pre-eminently well.—*Dr. Morell Mackenzie, in the Fortnightly Review.*

Reports of Societies.

British Medical Association.

FIFTY-THIRD ANNUAL MEETING.

Held at Cardiff, on Tuesday, Wednesday, Thursday, and Friday, July 28, 29, 30, and 31, 1885.

(DIRECT CABLE TO THE MEDICAL RECORD.)

Tuesday, July 28th—First Day.

President: James Cuming, M.D., F.K.Q.C.P., Professor of Medicine in Queen's College, and Physician to the Royal Hospital, Belfast.

President-elect: W. T. Edwards, M.D., F.R.C.S., Physician to the Glamorgan and Monmouth Infirmary, Cardiff.

The fifty-third annual meeting of the British Medical Association was held at Cardiff, the chief city of Wales. The general session was opened Tuesday morning by the retiring President, Dr. James Cuming, who made a brief address thanking the Society for the honor it had conferred upon him, and expressing gratification at the progress and prosperity of the Association, especially in the amount of scientific work done.

Upon concluding his address, a vote of thanks was moved by Mr. McNamara, seconded by Mr. Husband, and carried.

Dr. Balthazar Foster, President of the Council, then moved that the report of the Council (published in the *British Medical Journal*) be adopted. This motion was seconded by Mr. Power.

A long discussion then followed with regard to the project of

BUYING A SITE AND ERECTING A BUILDING

for the use of the Association. Those opposing the project said that the estimated cost of the site was $75,000, that of the building $50,000, making a total of $125,000. In reply to this charge of great expense, it was said that the Association absolutely needed larger premises; that it would be cheaper in the end for it to do its own printing; and, besides, it could probably get a building at a less cost than that estimated. Finally it was voted to adopt the Council's report and authorize it to buy or lease a site and erect a building thereon for printing and publishing the *Journal*, with offices, council-chamber, reading-rooms, etc.

The President-elect, Dr. W. T. Edwards, then delivered the

ANNUAL ADDRESS.

After having expressed his thanks for the honor conferred upon him, the speaker, in behalf of the profession of Cardiff, gave a cordial welcome to the visitors. He then gave some description of Cardiff. It was, he said, the age of great towns, and Cardiff had, owing to its mineral resources and other natural advantages, become one of the greatest of them. If, however, the estimates

were correct, and all the coal of that region were consumed in the next hundred years, Cardiff would soon collapse. Some account was given of the Cardiff schools, hospitals, and of Cardiff sanitary work. Prevention, he said, was not only better but cheaper than cure. The health officer of to-day stands, as did the Hebrew priest of old, between the living and the dead. Cardiff had many historic memories connected with it. King Arthur was said to have been born within its walls.

The rapid growth of the British Medical Association was eloquently described. It had now, he said, become a power in the country, socially, politically, and morally.

Dr. Edwards enumerated some of the additions to medical science and art that had been made during the period of the society's prosperity. Such were chloroform, ether, iodoform, the bromides, the immense advance in our knowledge of disease-germs, the introduction of antisepsis, etc.

The speaker, in conclusion, gave some statements showing the economy of preventive medicine. The cost of a single ironclad would, he said, save many lives.

At the conclusion of the address, a vote of thanks was moved by Dr. Strange, seconded by Dr. William Roberts, and unanimously carried.

Wednesday, July 29th—Second Day.

Dr. William Roberts delivered the

ADDRESS IN THERAPEUTICS.

(See page 115.) The address was received with marked attention; at its conclusion Dr. Chadwick moved and Mr. McNamara seconded a vote of thanks.

The Association then passed to a discussion as to the

PLACE OF THE NEXT ANNUAL MEETING.

Brighton was finally selected.

The work in the sections was then begun. In the Section on Medicine, the President, Dr. Samuel Wilks, of London, delivered an address. Diseases, he said, arose originally from peculiarities of climate, race, food, and the surroundings. Later the influence of heredity entered and is now potent. He had long taught that in all diseases of slow origin and progress the predisposing and exciting causes were identical. Dr. Wilks referred to the present ascendency of bacteria and bacilli in pathology, and believed that the fashion would in a measure pass away. Therapeutics, he said, was not really before pathology; the latter really leads. The nature of a disease must be known before therapeutics can achieve its greatest results.

Dr. Wilks called attention to the views about zymotic ferments as set forth by Liebig, and showed how these views had fallen through. Thus, on the so-called zymotic diseases, where ferments were to be expected, they had not been found, while microbes were found in phthisis, cholera, etc., where there is no analogy between the symptoms and those of specific diseases. The notion that each microbe has its specific pabulum he thought absurd, and the search for specific causes of disease by pathologists he thought very difficult, if not impracticable. Disease was often the result of irregularities in development of organs and lack of harmony in functions of kidneys, spleen, lungs, heart, etc. The best physicians survey the whole system and attempt to regulate properly these organs. As illustrating

IRREGULARITY OF FUNCTIONAL ACTIVITY,

the speaker described the curious intermittent or remittent action of many organs, occurring daily, or rhythmically night and day. No organ acted steadily and constantly.

He called attention, in conclusion, to the fact that pathological changes were of two kinds, reparative and destructive, and this fact should be borne in mind by the therapeutist.

At the conclusion, a vote of thanks was moved by Dr. Canning, and seconded by Dr. Roberts.

A discussion then followed on the

TREATMENT OF ACUTE RHEUMATISM.

It was opened by Dr. J. S. Bristowe, and participated in by Drs. Latham, Coupland, Prosser James, W. K. Thomas, Skerritt, Pavy, Harkin, and Wilks. The general tenor was in favor of the use of the salicylates. The blister treatment did not receive endorsement.

Papers were then read by Dr. L. Duncan Bulkley on "Asthma as Related to Skin Diseases," and by Mr. C. R. Straton on "Chorea, its Pre-ataxic Stage."

In the Section on Surgery an address was delivered by its President, Dr. E. H. Bennett, of Dublin.

The speaker took up the subject of the

BEST METHOD OF STUDYING FRACTURES

and injuries of the skeleton. The best method, he thought, was not by dissecting cadavers or experimenting on animals, but by collecting together many examples of the same kind in ordinary surgery. He had, in illustration, collected for study fifty-one cases of Pott's fracture. He had found that there were two forms of this injury, and that impaction was common. He had seen twenty-five cases of fracture of the costal cartilages, concerning which there were some peculiarities that needed further elucidation. A form of fracture of the upper part of the fibula oblique, without much displacement, was caused by a sudden jar, the foot being extended. Of fractures of the metacarpal bones, that of the thumb was most commonly affected. The fracture usually occurs close to the proximal end of the joint, and the whole bone slips back. The hand remains disabled for a long time.

A recent dissection and various specimens were shown.

A discussion upon Dr. Bennett's address followed, after which

Mr. Reginald Harrison opened a

DISCUSSION UPON TUMORS OF THE BLADDER.

(See p. 113.) To the discussion that followed Mr. Humphreys added letters received from Mr. Cadge and Mr. Annandale.

Papers followed by Mr. W. Adams, on the

SO-CALLED CONGENITAL DISLOCATION OF THE HIP-JOINT;

by Dr. J. Ward Cousins on "The Treatment of Infantile Hernia and a new Washable Splint," by J. Davies Thomas on the "Treatment of Pulmonary Hydatid Cysts by the Establishment of Large Openings into the Sac and Subsequent Free Drainage, based upon Thirty-two Cases."

IN THE SECTION ON OBSTETRIC MEDICINE

an address was delivered by the President, Dr. Henry Gervis. He referred to the decline in the general death-rate of late years, and then to the decline in the deaths from childbirth. He expected that this decline would continue. He recommended the more frequent early and judicious use of the forceps, the more careful study of contracted pelves, great precautions for the prevention of hemorrhage, and the use of antiseptics. These latter were equally important before and during labor. The more healthy the surroundings and the more vigorous the patient the fewer the germs and the less the danger from them. The use of the antiseptic spray was seriously suggested, but its practical difficulties admitted. He advised regular antiseptic bathing and syringing after labor, a careful examination of the parts, and stitching up of lacerations. Advised sublimate solutions or boric acid. He referred to the results of the collective investigation in support of the use of vigorous antiseptic measures in childbirth.

He discussed the subject of Puerperal Fever, and said that morbid anatomy must still further correct clinical study.

In the Section on Public Health the discussions were chiefly devoted to cholera.

Dr. R. Pringle read an article on "Cholera."

Dr. H. J. Paine read a paper on "Cholera and other Zymotic Diseases in their Relation to Sanitation, Practically Illustrated."

Dr. J. Maunsell read a paper on "The Various Schemes for Medical Aid with a View to their Adaptations to the Requirements of the Present Day."

In the Section on Therapeutics a discussion on the "Duration of the Action of Medicines" was started by Professor Leech, and a discussion on "Hypodermatic Medication" by Dr. Talfourd Jones.

(To be continued.)

THE VIENNA SOCIETY OF PHYSICIANS.

Stated Meeting, June 19, 1885.

Professor Leidesdorf in the Chair.

(Special Report for The Medical Record.)

This, the last meeting before the summer vacation, was called to order by the President, who regretted that the attendance was not larger, but hoped that, after the long rest, the members would be present in large number at their next meeting in the fall.

Professor M. Rosenthal presented a patient suffering from

LEAD PARALYSIS.

The patient was an actor who had been in the habit of employing lead paints upon his face. The paralysis affected the extensor muscles of the right hand.

He also showed a case of

HEMIANÆSTHESIA

following diphtheria. The patient, a young girl, had complete loss of sensation of the skin covering the entire right side of the body, together with paresis of the muscles of the palate and of the vocal cord on the same side. There was, however, hyperæsthesia of the right brachial plexus. The muscular sense was unimpaired.

Dr. Guido Schwab reported a case of

TRAUMATIC ANEURISM OF THE COMMON CAROTID ARTERY.

The patient was a woman, forty-one years of age, who had inflicted upon herself, with suicidal intent, a number of wounds in the neck with a pocket-knife. When seen two hours after the injury was inflicted she was found to have several wounds in the left side of the neck, from which a few drops of venous blood were exuding. The tissues in the neighborhood of the wounds were very greatly swollen. An iodoform dressing was applied and maintained in position for five days. Upon its removal at this time a distinct bruit was perceptible in the space between the heads of the sterno-cleido-mastoid muscle. Two months later a tumor, the size of a hazel-nut, easily compressible, was found in the left side of the neck along the course of the common carotid artery, at about the level of the conoid ligament. The swelling presented an expansive pulsation and a strong fremitus was perceptible. On auscultation of the tumor, as well as of the ascending and descending aorta, a loud murmur, synchronous with the cardiac systole, could be heard. This murmur as well as the pulsation ceased upon compression of the carotid below the seat of the aneurism.

Dr. Riehl then read a paper embodying the results of his investigations upon the

PIGMENTATION OF THE SKIN IN ADDISON'S DISEASE.

These confirmed the assertion of Nothnagel that the pigment in this disease is not elaborated in the epidermis, but is found in the deeper layers of the skin, sometimes massed around the vessels, and is deposited there by the blood. The writer had made microscopical examination of the vessels of the skin, and had found the adventitia in all cases remarkably nucleated. The cell-infiltration was found not only in the pigmented, but also in the colorless portions of the integument. In the arterial twigs of the cutis the media was also swollen and indistinctly pigmented. In some cases he found thrombi of the small arterioles. Since these arterial lesions were found in the entire integument, even in the non-pigmented portions, and also in some of the subcutaneous tissues and some of the internal organs (liver, peritoneum, and pleura), but thrombi only in the skin and suprarenal capsules, the author concluded that the arterial disease was primary and the cause of the deposit of pigment from the blood.

Professor Meynert read the last paper, entitled

THE RADIATION FIBRES OF THE ANTERIOR LOBES.

The author stated that choreic movements might proceed from the anterior cerebral ganglion, from the pons, or from that portion of the gray matter of the cord where the pyramidal tract ends, though in most cases they originated in the first-named portion of the central organ. He opposed Unvericht's theory that epilepsy depends upon an arterial neurosis and originates not in the cortical substance but in the subcortical motor centres.

The Society then adjourned.

Substitute for Morphine.—A correspondent from Milton, Wisconsin, writes: "When morphine or opium makes a patient wakeful or crazy instead of quieting them, what substitutes or combinations of opium will agree with them? You will confer a favor on me by publishing an answer to this."

AMERICAN OTOLOGICAL SOCIETY.

Eighteenth Annual Session, held at the Pequot House, New London, Conn., July 14, 1885.

C. H. Burnett, M.D., President, in the Chair.

Dr. Chas. J. Kipp, of Newark, N. J., exhibited the work of Gustav Retzius on the anatomy of the organ of hearing of vertebrate animals.

Dr. Samuel Sexton, of New York, read a paper on

INFLAMMATION OF THE ATTIC OF THE TYMPANUM.

The greater importance of inflammation arising in the attic as compared with that arising in the atrium was first referred to. Two forms of the affection were considered, acute and chronic inflammation of the attic, the latter presenting itself in the form of deep sinuses extending from the inner end of the canal up into the attic, into the antrum, and sometimes through the membrana flaccida.

The atticus tympanicus is that portion of the tympanum lying above a plane extending transversely from the prominence on the inner wall, formed by the external semicircular and facial canals, to the auditory plate on the outside. Beneath this plane lies the atrium tympanicum. The attic is divided below into two compartments, the inner being the larger, by the incus and malleus, the cord, ligaments, etc. These compartments communicate freely with each other, with the atrium, with the Eustachian tube, and with the antrum. These cavities are lined throughout with mucous membrane.

Acute inflammation of the attic may follow catarrh of the head, the exanthemata, and the entrance of fluids propelled along the Eustachian tube. The very frequent occurrence of inflammation of the attic from these causes is readily accounted for when we remember the Eustachian tube at its tympanic orifice opens by a free sweep into the attic as well as into the atrium. Irritating fluids seem always to be better borne in the lower than in the upper part of the tympanum. Inflammation of the attic may be simultaneous with, or independent of, inflammatiion of the atrium. It is the more serious from the fact that swelling of the mucous membrane prevents drainage. In such cases the membrana flaccida is red, the vascular turgescence extending above into the external auditory canal and sometimes downward about the short process of the malleus. Should the disease progress further, the inflammation may extend beneath the margo tympanicus of the auditory plate and be followed by effusion of serum and blood, which presses away the membrana flaccida and integument of the canal, producing a bulging sac so great sometimes as to entirely conceal from view the membrana tympani, and may entirely fill the canal and present at the lumen as a purplish tumor.

Periostitis of surrounding parts may occur and the inflammation may extend downward to the atrium, but as long as this does not happen and the membrana tympani is unaffected there may be little deafness. As a rule, inflammation in some degree extends into the antrum and mastoid cellules or those overlying the external auditory canal or in the tegmen. If the escape of secretions into the atrium or Eustachian tube is prevented, the case is more severe and extension to the cranial cavity more to be dreaded.

The subject of treatment resolves itself into a question of drainage and the employment of such constitutional remedies as tend to check the inflammation and prevent the formation of pus. Aconite and calx sulphurata were particularly referred to. Owing to the impossibility of making an accurate differential diagnosis between the pains of pachymeningitis and the neuralgic pains of otitis media, we should be very cautious about trephining the mastoid where pain is our only indication. It is manifestly useless to perform this operation after pachymeningitis has set in.

Dr. D. B. St. John Roosa, of New York, had nothing to venture in regard to the anatomy, but the remedies mentioned, mercury and calcium sulphide, are not in common use in the way recommended by the speaker. He had used mercury in doses of one-tenth to one-fifth grain and also sulphide calcium without any favorable effect. He asked Dr. Sexton to describe a case, indicating the manner in which he would use these remedies.

Dr. Sexton gives the remedies in small doses, frequently repeated. The moment there are symptoms of purulency calcium sulphide is given. He had seen congestion and swelling over the mastoid disappear under the use of the calcium.

Dr. J. A. Andrews, of New York, referred to a case in which the inflammation was most intense in the upper part of the tympanic cavity. A perforation was established between the mastoid, antrum, and external auditory canal. There was a fluctuating point in the superior posterior part of the canal, which was opened. The patient made a good recovery.

Dr. Sexton recommended for the relief of pain the use of aconite or pulsatilla, the latter especially.

Dr. C. R. Agnew said that with children there is always a certain amount of indefiniteness in the symptoms, and he asked Dr. Sexton what he would do in a case of acute otitis media catarrhalis in an infant six months old.

Dr. Sexton replied that he would examine the history, ascertain the general condition, whether it was subject to catarrhal trouble, the condition of dentition, and whether there had been a previous attack of inflammation of the middle ear. If there were accumulation, he would not hesitate to let it out. If there were suppuration he would give calcium sulphide, but if there was only catarrh, give mercury.

Dr. Charles J. Kipp, of Newark, N. J., was surprised to hear nothing said of inflation of the middle ear. This relieves the pain. Where there is protrusion in front of the membrane, incision gives relief to the suffering.

Dr. Theobald, of Baltimore, had found the instillation of a warm solution of atropia of great service (four grains to the ounce), with this cathartics may be combined with great benefit. After perforation of the drum membrane he would recommend the use of boracic acid.

Dr. C. J. Blake, of Boston, spoke of the reduplication of the mucous membrane in the upper portion of the tympanic cavity. This he had found in fifteen or twenty per cent. of two hundred specimens examined. They serve to separate the upper portion of the tympanic cavity from the lower, and are an important element in inflammation of this part, and may tend to retain secretions.

Dr. Sexton said, in conclusion, that he had used mercury and the sulphide of calcium for the last ten years in a large number of cases and was convinced that they are beneficial in a certain number of cases. If he was to give up anything, he would rather give up the local applications than give up these internal remedies.

A paper entitled

THE TREATMENT OF CHRONIC OTITIS MEDIA

was read by Dr. W. W. Seely, of Cincinnati, in which the speaker alluded to the abandonment of the nasal douche and the posterior nares syringe, and held that all applications to the naso-pharynx should be made with care, as all were liable to do harm. All of the points thus far were to justify the author's condemnation of the slurring of these cases by specialists in various ways, such as putting the catheter or balloon into the hands of the patient or parents, throwing over the treatment of the throat also to the patient. He claimed that this class of cases were almost all amenable to treatment, and only time and patience were necessary to manage them.

The speaker thought that the attention of the general profession was becoming too much centred on the Eustachian catheter as the only means of treatment, and especially as the only means of opening the tubes. Often

catheterization does harm rather than good, and some application of boric acid and vaseline, or, what is still better, of the yellow oxide of mercury and vaseline through the nostrils, will open the tubes, while the catheter has little or no effect. He said that salves had almost if not quite supplanted all other applications for nasal and naso-pharyngeal troubles.

The speaker concluded his remarks with the following propositions:

1. That only experience of sufficient length of time (often lasting over months) in each case can determine whether treatment shall be continued (daily), or interrupted, *i.e.*, perhaps daily for a week, followed by an interruption of some weeks or months.

2. Only experience in each case can inform us whether treatment is to be entirely directed to the middle ear, or entirely to the naso-pharynx or combined against both.

3. Only experience in each case can inform us whether injections into the cavitas tympani are called for. Under this head it was stated that direct medication, either of the middle ear or naso-pharynx as routine treatment was unwise, till simple inflation had failed.

4. Mechanical dilatation of the tubes is rarely necessary or advisable. Only in extremely dry states of the tube is dilatation followed by much success.

5. Hearing-tests are not reliable, and hence patients with great deafness, great loss of bone conduction, etc., should not be sent away till the test by trial has been gone through with.

6. Simple inflation failing, the greatest attention should be given to the naso-pharynx, even though it is in an apparently fair condition.

7. Syringing, douching, and swabbing the naso-pharynx should be abandoned.

Dr. Charles H. Burnett, of Philadelphia, read a paper on

THE RELATIONS BETWEEN CHRONIC CATARRHAL OTITIS MEDIA AND CHRONIC RHINITIS.

The author finds: 1. A constant causal relation between chronic catarrh of the middle ear and chronic rhinitis and rhino-pharyngitis. The latter is chiefly of the hypertrophic form. The atrophic form, which is made to include the fibrous degenerations and the sclerotic forms, as well as the truly atrophic, with shedding of epithelium and exposure of basement membrane, constitutes about fourteen and one-half per cent.

2. The appearances of the membrana tympani in the first or numerous class are very diversified, so much so as to preclude a predication of the state of the middle ear and hearing from them alone. In the second class, however, the atrophic, the symptoms presented by the membrana tympani are more uniform and consistent, and the surgeon is able to predicate from them more precisely concerning the aural disease. Yet, on the whole, the appearances of the drum, taken by themselves, cannot aid greatly in the diagnosis of chronic aural catarrh. The faucial symptoms play a very subordinate part in diagnosis in chronic catarrh of the middle ear, because faucial and throat disease have little or no causal relationship to aural disease.

3. Tinnitus aurium is more marked in the atrophic class than in the hypertrophic, as a rule. There is also a greater patency of the Eustachian tube in the atrophic forms of aural disease than in the hypertrophic, though it is found in both forms of naso-aural disease. It is most relieved by treatment of the nares and naso-pharynx.

4. The treatment in the first class should be by cleansing and astringent sprays, with applications of preparations of iodine never stronger than half-and-half. Nitrate of silver is not to be used at all in hypertrophic rhinitis. In the atrophic form, the treatment must be cleansing, the removal of inspissations, if they occur, and then the application of stimulant sprays, preferably nitrate of silver, not stronger than four grains to the ounce of water.

Where the hypertrophies have become dense and large, requiring surgical removal, Dr. Burnett thinks the case should pass into the hands of the rhinologist.

A word of caution is given in regard to the use of the galvano-cautery in the nares, since it, like the nasal douche, may lead to inflammation in the naso-pharynx and middle ear. The aural surgeon should always examine the nares, being prepared to treat the non-surgical forms of chronic rhinitis in order to properly cope with chronic aural catarrh.

Dr. Agnew, of New York, thought it was impossible to apply salves to the whole of the diseased surface by means of Bowman's probe. He was not prepared to abandon the nasal syringe. He thought more stress should have been laid on the importance of hygiene, which is the most important element in the treatment.

Dr. Roosa agreed with the last speaker that the principal and only benefit to be obtained in the majority of these cases is from proper hygiene. He thought that we need not continue our examinations very long or repeat them very often to determine whether or not we may expect to give the patient any relief. If he finds diminished bone conduction he considers it unnecessary to go on and treat that patient.

Dr. E. Williams, of Cincinnati, had been in the habit of using the Eustachian catheter in every instance where he thought it indicated. Not only so but he often introduced a flexible bougie through the catheter sometimes into the middle ear. In some cases of stricture of the tube this is quite useful.

Dr. Seely said that since he had adopted the use of salves as a routine treatment he had had more satisfaction than by any other treatment. They remain longer in contact with the affected part than do solutions, thus giving a more decided effect.

Afternoon Session.

Dr. Sexton presented a conversation-tube for the aural instruction of deaf-mutes. By means of this tube the patient was able to hear his own voice and compare it with the voice of his teacher.

Dr. Graham Bell was then introduced and called the attention of the Society to the greater number of children who were classed in institutions as deaf-mutes, but who, under proper treatment and education, could be made simply hard-hearing members of society. He also referred to the importance of otologists formulating a list of causes of deafness to facilitate the proper registration in institutions for this class of individuals.

Dr. Charles J. Kipp, of Newark, N. J., presented the history of

A CASE OF FATAL EAR DISEASE, BEGINNING AS A CIRCUMSCRIBED INFLAMMATION OF THE EXTERNAL AUDITORY CANAL.

The patient, a married woman, aged twenty-eight, was first seen nine months before her death. Since the previous confinement, which occurred four months before coming under observation, she had suffered occasionally with severe pain in and about the left ear. There was swelling and redness of the posterior upper wall of the external canal. There was no perforation and no otorrhœa. Under the use of leeches, instillations of morphia, and inflation of the middle ear, there was decided improvement in the course of a month, when she passed from under observation.

Eight or nine months later the pain again appeared, shortly after a confinement. Examination showed furuncles in the ear. There was no involvement of the middle ear. The patient soon recovered from this, but was subsequently attacked with severe pain in the head. There was no evidence of mastoid disease. The patient shortly afterward died.

At the autopsy there was found evidence of intense inflammation over the entire extent of the arachnoid and pia mater. There was a collection of pus immediately over

the posterior surface of the petrous portion of the temporal bone. Pus was also found on the pons varolii. A small abscess was found in the anterior part of the left lobe of the cerebellum near its junction with the pons. The mastoid cells were filled with pus. There was only a thin exudation in the middle ear.

Dr. Burnett reported a similar case in which the patient died from what was diagnosed as cerebral abscess, but no autopsy could be obtained.

Dr. E. E. Holt, of Portland, Me., reported

THE PRESENT CONDITION OF A PATIENT FROM WHOM TERATOID TUMORS WERE REMOVED TWO YEARS AGO.

The patient had remained free of the disease for one year, when they again appeared and have since progressed quite rapidly.

THE LOCAL USE OF COCAINE AND BRUCINE IN DISEASES OF THE EAR

was the title of a paper read by Dr. C. H. Burnett, of Philadelphia. The speaker had employed both the sulphate and hydrochlorate of cocaine in painful affections of the ear to produce anæsthesia. He found neither efficient when the pain was due to inflammation in dense tissues of the external auditory canal, as in furuncle of this part, nor when acute inflammation occurs in chronically thickened periosteal and mucous tissues in the tympanic cavity. The hydrochlorate of cocaine, however, is efficient to induce local anæsthesia in four per cent. solution, in cases of not excessive congestion of the skin of the fundus of the auditory canal and in the membrana flaccida of the drum membrane, as is observed in acute coryza attended with pain of a not continuous or intense variety. The solution may be applied to the inflamed tissues either by mopping it gently upon the affected portion, or by soaking a small dossil of lint and laying it upon the seat of inflammation, both procedures being done under perfect illumination of the fundus of the auditory canal by means of the forehead-mirror. But solutions of cocaine are not competent to produce local anæsthesia in the external auditory canal profound enough to permit painless incision into it. Local anæsthesia in the membrana tympani, prefatory to paracentesis, is not required, as the operation is not painful enough to demand local anæsthesia.

The Doctor had also used brucine in five per cent. solution with decided success in several cases of ear trouble, and had produced decided anæsthesia with it.

Dr. E. E. Holt, of Portland, Me., read a paper entitled

DOES COCAINE HYDROCHLORATE, WHILE RELIEVING THE PAIN IN ACUTE OTITIS MEDIA, PROLONG THE CONGESTION?

The Doctor concluded that while cocaine relieved the pain and for the time holds the inflammation in check, yet after the effect of the remedy passes off, the inflammation goes on unaffected.

Dr. H. Knapp, of New York, read a paper

ON THE DESIRABILITY OF ADOPTING A UNIFORM METHOD OF EXPRESSING THE RESULTS OF TESTING THE ACUTENESS OF HEARING.

The following nomenclature was suggested in which the plan pursued in recording the condition of vision is applied to the hearing:

$H=\frac{4}{4}{}''$, normal audition for watch.

$V=\frac{20}{20}$, normal hearing for whispered voice.

$V=\frac{20}{20}$, normal for conversational speech.

$V=\frac{20'}{8}$, whisper or speech heard, but not understood, *i.e.*, qualitative perception of sound.

$V=60'=O$, voice not heard at all; $H=O$, complete deafness for all sounds.

$H=\frac{c}{24}{}''$, watch of 24″ hearing distance is heard in contact.

$H=\frac{Tr}{24}{}''$, watch of 24″ hearing distance is heard when pressed on ear.

$H=\frac{M}{24}{}''$, watch of 24″ hearing distance is heard when applied to mastoid.

$H=\frac{T}{24}{}''$, watch of 24″ hearing distance is heard when applied to temple.

$H=\frac{O}{24}{}''$, watch of 24″ hearing distance is heard when applied to teeth.

$H=\frac{Gl}{24}{}''$, watch of 24″ hearing distance is heard when applied to forehead (glabella).

$H=\frac{V}{24}{}''$, watch of 24″ hearing distance is heard when applied to vertex.

$H=\frac{Ub}{24}{}''$, watch of 24″ hearing distance is heard when applied everywhere (ubique).

To indicate that the watch is not heard at the places indicated, the following are used: $H=\frac{c}{24}{}''=O$, $H=\frac{M}{24}{}''=O$, etc., means that the watch is not heard in contact over mastoid, etc.; $H=\frac{Ub}{24}{}''=O$, means that bone conduction for the watch is lost.

Dr. Knapp was appointed a committee of one to present the matter at the coming meeting of the German Naturalists and Physicians.

PRESBYKOUSIS.

Dr. D. B. St. John Roosa, of New York, applied this term to the failure of hearing which is incident to old age and which is not dependent upon inflammatory affections. It comes on after the age of forty or fifty years. Such persons hear badly in a noisy room. They hear the watch badly, but in a quiet room they can hear quite well. This is characteristic of this affection. In inflammatory troubles with the ear, the person often can hear pretty well in a noise, while in a quiet room he hears badly. These three symptoms go together: diminished bone-conduction, hearing worse in a noise, and the disproportion between the ability to hear the voice and the watch. The conditions on which this presbykousis is dependent has not been determined, for as yet there have been no opportunities for post-mortem examinations.

Dr. H. Knapp thought the term presbykousis was not a good one, because if used in analogy with presbyopia it would indicate a diminished range of accommodation of hearing, which would refer more to pitch than anything else. What is meant is senile involution, which occurs in every organ.

Dr. Roosa, in conclusion, said that he thought the term presbykousis applicable, as its meaning was simply the hearing of old age. In regard to the hearing better in a noise, he was convinced that patients with tympanic disease could hear better under such circumstances. He cited the example of a lady who heard with difficulty under ordinary circumstances, but who in a boiler-shop heard the ordinary voice distinctly while her husband with normal hearing, heard only when words were shouted.

Dr. Sexton exhibited a glass ear-syringe and an ear-forceps with several attachments.

Dr. E. Dyer, of Newport, R. I., reported a case of fistula of the helix in a girl of fourteen.

The following papers were read by title: "A Case of Chronic Otitis Media Suppurativa, resulting in Cerebellar Abscess, with the Autopsy," by Dr. O. D. Pomeroy, of New York; "Otitis Media Suppurativa, Mastoid Disease, Pyæmia, Mastoid Operation, Recovery," by Dr. G. Bacon, of New York.

The meeting then went into executive session.

The following officers were elected:

President—Dr. J. S. Prout.

Vice-President—Dr. S. S. Sexton.

Secretary and Treasurer—Dr. J. J. B. Vermyne, New Bedford, Mass.

Publication Committee—Drs. Vermyne, Blake, and J. O. Green.

Committee on Membership—Drs. Carmalt, Kipp, and Theobald.

Dr. F. L. Capron, of Providence, R. I., was elected to membership.

The meeting then adjourned.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

MR. WOOD'S LECTURES ON THE RADICAL CURE OF HERNIA —MR. LUND ON RECTAL AFFECTIONS—THE ELECTION AT THE COLLEGE OF SURGEONS—DISFRANCHISEMENT FOR MEDICAL RELIEF.

London, July 4, 1885.

An interesting historical *résumé* of the subject was given by Mr. Wood in the concluding lecture of his course at the College of Surgeons on "Hernia and its Radical Cure." It was, I am sure, news to many of his hearers that Celsus practised excision of the sac and its covering; and that Galen and Paulus Ægineta ligatured the sac at the superficial ring, and tied up also the cord and skin. These and many other interesting historical particulars were recounted by the lecturer. Coming to more modern times, Mr. Wood made the just protest that his name had been applied to operations in which all his precautions were neglected, and also to the employment of a part of his operation only as the basis for a new method. The result, in many cases, he said, had been a want of success, for which, not the operation, but the operator, was really responsible.

Mr. Wood maintained that the position of those who maintained that the radical cure should not be attempted except in the severest cases was untenable. In conclusion, he enumerated the rules he had adopted in his own cases. He said he had adopted the subcutaneous plan:

1. In cases of children above five years of age in whom trusses were useless or unavailable.

2. In cases of young adults, or boys under fourteen, whose prospects in life were seriously impaired by the hernial condition.

3. In reducible cases, where the sac was thick and indurated from truss-pressure, or where the omentum continually slipped down under the truss, thus showing that it was abnormally elongated. He opened the sac, tied the vessels of the omentum separately, and removed it below the ligatures. The neck of the sac was tied up flush with the peritoneum at the deep hernial opening, and wire or tendon-ligatures applied to the canal and rings.

4. In all favorable cases of strangulated hernia (both inguinal and crural), the coverings and front wall of the canal being necessarily divided to search for the constricting tissues, he opened the sac, examined the contents, removed adhesions and doubtful portions of omentum, then tied up the neck of the sac, cut it off short, and removed it altogether (except in congenital hernia), and secured the walls of the canal and rings, as in the subcutaneous method.

5. Cases of irreducible hernia, and of large and unmanageable cases of reducible hernia, in patients otherwise in good health and not above sixty, and in which truss-pressure entirely failed to render the patient comfortable and free from danger, seemed (said the lecturer) to justify and require operation (under strict antiseptic methods). In these cases, as in the last class, the operation assumed more or less of the character of an open operation under spray. The sac was freely opened, tied and removed, but the suturing of the canal and rings was effected as in the subcutaneous method.

In Mr. Lund's third lecture he spoke of the value, in cases of proneness to diarrhœa and irritability of the lower bowel, of making a careful digital rectal examination. He referred to a case of this kind in a lady which was by this means shown to be due to the irritation of a fibroid tumor in the pelvis. In another case, a surgeon about to operate on a fistula discovered an epitheliomatous deposit, with contraction of the bowel and a corresponding dilatation above, with rupture and abscess as a starting-point for the fistula. The operation was thus rendered useless. In discussing the operative treatment of fistula, Mr. Lund indorsed Mr. Curling's axiom, that the surgeon who operates for fistula should be his own dresser. While the incisions are being made, he avoids the use of water or wet applications to the part. Any blood or pus is removed by pieces of dry lint or linen cloth. After the operation, Mr. Lund said he used carbolated castor-oil to protect the freshly-cut surfaces from the irritation of fæces, mucus, or flatus. The oil should be so prepared as to be clear and bright, and, if applied freely, no washing of the part is necessary.

The annual election of members of Council at the College of Surgeons was held on Thursday. In spite of his known opposition to reform, Mr. Savory was returned at the head of the poll. The other successful candidates were Mr. Pemberton, of Birmingham, and Mr. Macnamara, of the Westminster Hospital. Both these latter gentlemen have declared themselves in favor of reform, and both have been strongly supported in their candidature by the Council of the Association of Fellows of the College of Surgeons.

The question of disfranchisement for medical relief, though not exactly a medical question, or at any rate only partially so, is exciting a good deal of interest just now. As originally drafted, the recent Franchise Bill did not disfranchise persons who received medical relief. By an amendment inserted in the House of Lords, however, such persons *resident in England* were disfranchised, though the amendment was not made to apply to Ireland. A good deal of agitation is now going on against this clause in England. Some people appear to think that being attended by the parish doctor does not make a man a pauper, though the acceptance of food or lodging from the parish does. Medical men who have large opportunities of judging of the character of the proposed new voters seem to regard them with but little confidence, and are inclined to argue that these people will never be provident so long as they are encouraged to look to the State to provide them with medical attendance.

OUR PARIS LETTER.

(From our Special Correspondent.)

DISCUSSION ON ERYSIPELAS — TEST FOR DIGITALINE — ASEPTOL.—NEW HOSPITAL AT HAVRE.

Paris, July 3, 1885.

In expressing his opinion on the debate that has occupied so many meetings of the Academy of Medicine, Dr. Dujardin-Beaumetz stated that he could not understand why so much time and controversy were devoted to the subjects of erysipelas, particularly as nothing new has been added to our knowledge of the pathology, etiology, and the treatment of this affection. Erysipelas, he added, was a very common affection in the medical wards, and is in general rather benign; death from it was altogether the exception. Professor Hardy entirely agreed with this opinion. During the last ten years that he has been clinical professor at one of the largest hospitals in Paris, he has seen a very great number of erysipelatous patients, and among them there were only three deaths, and yet it cannot be said that the three patients died from erysipelas, as they were at the same time the subjects of other affections which, of themselves, were of a fatal character. Dr. Féréol remarked that there was a wide difference between medical and surgical erysipelas, and that the gravity of the former was not to be compared to that of the latter. It is, however, generally admitted that erysipelas is a highly contagious disease, and many of the speakers expressed their surprise at the promiscuity of erysipelatous patients with those suffering from other ailments. This led to the proposition emanating from Professor Verneuil that special wards should be constructed with the view of isolating erysipelatous

patients from the others. There is no doubt that there is much to be done in this direction, and it is a crying disgrace to a country that is supposed to be in the van of civilization to have no special arrangement at this period of medical history for the accommodation of persons suffering from infectious or contagious maladies, and yet millions of money are spent on objects much less useful.

Very great difficulty often attends the testing for digitaline, the coloring re-agents indicated by authors being so little distinct and varying according to the source of the samples on which experiments are performed. M. Lafon, in making some researches, found a new re-agent which is very sensitive, and permits one to differentiate more distinctly than has up till now been possible the numerous products employed in therapeutics under the name of digitaline. This process consists in treating a trace of this substance by a mixture of sulphuric acid and alcohol, and adding to the mixture one drop of the perchloride of iron. A beautiful greenish-blue tint is immediately produced which is altogether characteristic and lasts for several hours. These results were submitted at a recent meeting of the Academy of Sciences.

At the same meeting M. Serran drew the attention of the members present to the antiseptic, antiputrid, and antifermentescible properties of orthoxy phenylsulphurous acid or aseptol—a syrupy liquid, of a pink or reddish color, of a slight special odor, not so disagreeable as carbolic acid, over which it presents, according to the author, a real superiority, on account of its great solubility in water—to its being much less toxic, and to its antiseptic qualities being three times greater than those of carbolic acid. Aseptol can be administered internally in very large doses without the least inconvenience, whereas carbolic acid, in doses three times smaller, produces the gravest accidents.

A new hospital was opened at Havre last week in the presence of the official authorities of that town and of the Department of Calvados. The Prefect of the Seine, and the Presidents of the Academy of Medicine, and of the Société de Médecine Publique, were also present. This is an institution that was much needed in that important seaport. The hospital, which covers an area of 65,000 square metres, or 71,108 square yards, consists of seventeen detached pavilions, which are well ventilated and have a sunny aspect. They are built over a subbasement, raised to a good height, in which are established promenades for wet weather, reading and recreation rooms, calorifers, etc. The wards, which are on the ground-floor, are lofty, measuring seven metres, or about twenty-three feet, in height. The roofs are ogival, and the walls are varnished so that they may be easily washed. The floor is mosaic, which I think is a mistake, as however closely the pieces may be joined together the dust will accumulate between them. The pavilions, eleven only of which are devoted to patients, have double walls, and the air that fills the space between them being a non-conductor protects the wards against sudden changes of temperature. The hospital is lighted by electricity, and is furnished with all the modern appliances for disinfecting furniture, linen, etc., which are established underground, and to which persons from the exterior can also have recourse. There is also every variety of baths, which are equally open to the public. A pavilion is set apart for contagious and infectious diseases, another for cases undefined, and one for convalescent patients.

The hospital was built at great expense, and can furnish 312 beds, each bed costing $1,200, and each patient has a cubic space of 50 metres, or 164 feet, 0.539 inch, which seems to me far below that allowed by the ordinary rules of hygiene.

A fortnight ago Dr. Gibier was sent to Spain by the Minister of Commerce to study the progress of the cholera epidemic in that country, and the results of Dr. Ferrán's inoculations as a preventive of the disease. The French Government has also sent a mission to Spain with the same object. This mission is composed of Drs. Brouardel and Charrin, and M. Albaran, who is an interne and a native of Cuba.

PRELIMINARY REPORT OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION — REPLY TO DR. DUGGAN'S CRITICISMS.

To the Editor of The Medical Record.

Sir: My absence in Europe has prevented an earlier reply to Dr. Duggan's criticisms. It was hardly to be expected that a *preliminary* report, made, by special request, before the experimental investigations undertaken by the Committee were completed, would be beyond criticism. But the writer has been surprised that a criticism of this character should have been made by one who has been daily working in the same laboratory with him, who for a time was his trusted assistant, who has received compensation and full credit for all work done by him, and who has had ample opportunity to personally call attention to the points which he has seen fit to criticise publicly. This seems the more remarkable in view of the fact that I asked Dr. Duggan if he had any criticisms to make soon after the publication of this report, when there was still time to revise it, if necessary, before it had been placed in the hands of the public.

Moreover, the only part of his criticism which is valid was uncalled for, inasmuch as the "Disinfecting and Antiseptic Powder" had been withdrawn in a communication to the *Medical News* of May 2d, more than a month prior to the publication of Dr. Duggan's paper in The Medical Record, June 6th.

The writer alone was responsible for this powder, and freely confesses that he made a chemical blunder in his attempt to combine in the same formula the two potent germicides, mercuric chloride and chloride of lime. The mistake arose from the fact that in the powder, made as directed, the yellow oxide of mercury is not formed, and the two active ingredients remain indefinitely, in sealed packages, without undergoing change. *It is only when water is added that the reaction* occurs. But this is fatal to the usefulness of the powder.

Having made this free confession with reference to my unfortunate chemical blunder, I shall briefly consider the other criticisms made by Dr. Duggan; but first it seems necessary to state certain facts, which will perhaps explain why he has seen fit to rush into print with his criticisms when he had daily opportunity to call my attention personally to the points he has attempted to make.

In carrying out a series of experiments upon commercial disinfectants under my direction, by my method, and at the expense of the Committee on Disinfectants, Dr. Duggan had his attention drawn to the superior value of Labarraque's solution, as compared with the various proprietary disinfectants tested. This led to his giving special attention, at my request, and at the expense of the Committee, to the hypochlorites. At the time these experiments were made, Dr. Duggan was (and I believe still is) in the employ of an enterprising firm of manufacturing chemists. I found that through him this firm was getting *points* with reference to our work which were of value in a commercial way, and which gave them an advantage over other manufacturers, whose products were being examined and reported upon. I found also that Dr. Duggan's work for his employers took so much of his time that he could not push the work of the Committee on Disinfectants as rapidly as I desired. I therefore placed the further examination of commercial disinfectants in the hands of my efficient laboratory assistant, Dr. A. C. Abbott. From this time Dr. Duggan ceased to give me the benefit of his chemical knowledge, and,

as the limited funds at the disposal of the Committee on Disinfectants did not enable me to secure the services of another chemist, I was thrown upon my own resources; for the chemists upon the Committee are not located within consulting distance of the laboratory in which I work.

What follows will show very clearly, however, that if a biologist may go astray on chemical questions, chemical experts are not infallible; and that something more than laboratory training is necessary in judging of practical questions relating to the use of disinfectants. This is shown by Dr. Duggan's criticism relating to the directions given for disinfecting clothing with Standard Solution No. 4. He says: "We would suggest burning the clothing as preferable to this treatment, for when they are taken out of this solution they will be of a dark yellow color," etc. Now as a matter of fact *no discoloration occurs* when soiled clothing is treated in the manner directed. A small piece of perfectly clean goods immersed in a considerable quantity of the solution, diluted as directed, is slightly stained, especially if distilled water is used in making the dilute solution. But the organic matter present in soiled clothing, and even in new goods, very quickly neutralizes the small amount of potassium permanganate present—less than half a grain to the gallon—and no discoloration occurs. A worn sock and two small pocket-handkerchiefs, slightly soiled, immersed in a quart of the disinfecting solution caused the color due to the presence of the permanganate to disappear in less than two minutes; a clean pocket-handkerchief immersed in the same quantity of the solution for two hours was very slightly stained. This possibility of staining was fully considered by the Committee before the recommendation was made, and since Dr. Duggan's statement that "burning the clothing would be preferable to this treatment," three members of our Committee have repeated the experiments, and find that this is something more than a gross exaggeration. From a practical point of view the objection is entirely without foundation. If the permanganate were really objectionable on this ground it would be a very simple matter to reduce the quantity prescribed "to give color to the solution," for ten or twelve grains per gallon would suffice for this purpose. The intention is to give color to the concentrated solution and not to the dilute solution, which is made by adding one ounce of this to the gallon of water.

So far as injurious action upon clothing is concerned Standard Solution No. 4 has a decided advantage over solutions of the hypochlorites on account of the bleaching action of those salts.

Again, with reference to the application of Standard Solution No. 4 to plastered walls, Dr. Duggan says: "*Of course*, Standard Solution No. 4 would color walls the same as it would clothing." It is not well for a critic to say "of course" about a thing of this kind when it is so easy to make the experiment. Two members of the Committee on Disinfectants have made the experiment, and are able to testify that *no discoloration occurs*.

The suggestion that the inmates of a room disinfected as directed might subsequently suffer from mercurial poisoning has no value, inasmuch as after the application of the disinfecting solution the walls and ceiling are to be "whitewashed with a lime-wash" (no yellow discoloration results from this), and "the floors and woodwork to be well scrubbed with soap and hot water."

The criticism which affirms that the addition of one pound of corrosive sublimate for every five hundred pounds of the contents of a privy-vault would accomplish little more than would be accomplished "by dropping a sulphur match into the vault," is hardly entitled to serious consideration. This criticism, moreover, is based upon the assumption that the mercuric chloride is to be added in solid form, whereas our directions explicitly state that it is to be used in solution. Dr. Duggan speaks of the difficulty with which mercuric chloride dissolves, and says that "in such a mass of fecal matter every particle of it would probably become encysted in an envelope of the insoluble albuminate, and remain so indefinitely." The Committee did not for a moment contemplate the use of the undissolved salt, and prescribed a standard solution on account of the difficulty with which mercuric chloride dissolves. After giving the proportion in which, in its judgment, this agent should be used, it explicitly directs the use of Standard Solution No. 4, diluted with three parts of water; and says further, "All exposed portions of the vault, and the wood-work above it, should be thoroughly washed down with the disinfecting solution."

For the disinfection of excreta, in small quantities, in the sick-room, the Committee has given precedence to the solution of chloride of lime (Standard Solution No. 1) on accounts of its rapid action. But for masses of material in privy-vaults the solution of mercuric chloride is preferred for the following reason:

The chloride of lime solution in contact with organic material is promptly decomposed, and if the organic material is in excess and a certain number of germs escape destruction, they may subsequently develop in the presence of fresh supplies of pabulum. But the mercuric chloride remains in the vault indefinitely in a potent form—for the albuminate of mercury is a potent germicide—its wonderful restraining influence upon the development of germs comes into play even when it is present in too small a quantity to destroy the vitality of germs with which it comes in contact. I would here call attention to the fact that I have demonstrated by actual experiment that mercuric chloride does sterilize semi-solid fæces, when a solution of one-half the strength of that recommended in our preliminary report is well mixed with the material (*Medical News*, February 21, 1885, p. 208).

Finally, I would say that the Committee on Disinfectants invites unprejudiced criticism, and will be glad to avail itself of all information attainable, in order to accomplish the whole object which it has in view, viz., to give the public the best possible information with reference to practical disinfection. But this object can be as well attained if the critics will communicate directly with the Committee, and this course will save valuable time and printer's ink.

I would say, in conclusion, that I do not understand what additional force Dr. Duggan's criticisms receive from the signature of C. T. McClintock, A.M., attached to his paper.

GEO. M. STERNBERG, M.D.,

Major and Surgeon U.S.A., Fellow by courtesy in Johns Hopkins University, *Chairman of the Committee.*

LETTER FROM THE CITY OF MEXICO.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: As your paper has more than once published correspondence from various places in this country, I hope the following will not be altogether without interest to your readers.

The most striking features of medical life and hygiene in this country and during the last few years have been the following:

1. A constantly and disproportionately increasing mortality in the capital of the Republic; having been a couple of years ago 240 to 250 per week, and having run up lately to 300 a week, the population being over 250,000, and probably not reaching 300,000. Certain it is that the population has increased during late years, but not in such a proportion as the death-rate; for ten years ago the population of the capital was already estimated to be 250,000. The above figures give the city of Mexico a yearly death-rate of 30 per 1,000, or 1 in 20; while the city of Guanajuato is still worse off than the capital, showing a death-rate of 74.4 per 1,000, or 1 in 13.4 a year, the population being 58,000 souls. The lead among the prevailing diseases

belongs to diarrhœa and other intestinal troubles (often of alcoholic origin), pulmonary complaints (pneumonia, bronchitis, tuberculosis), and typhus. A great deal has been talked and written about the causes of the daily growing worse hygienic state of this place, but nothing has been done. It is evident that the filth of three hundred and fifty or more years, and the absolute lack of drainage and sewers, must be the most important factors of such a pitiable condition.

2. Another important accident has been the appearance of severe epidemics of yellow fever on the Pacific coast of Mexico, a calamity that for more than two hundred years, it is said, did not take place. It is not ascertained how yellow fever this time happened to be carried across the continent; it may be that the work on the interoceanic railway over the isthmus of Tehuantepec, with a considerable accumulation of unacclimated people, had something to do with it. The places most cruelly visited, twice in two consecutive years, have been Colima, San Blas (where last year six hundred people died out of a total population of two thousand), and Guaymas in Sonora.

3. The investigations of Dr. Carmona y Valle into the origin of yellow fever and its protective inoculation. As your paper has already briefly mentioned the trials of Dr. Domingo Freyre and Dr. Carmona, it may be time to say a few words about the latter's ideas and practice. Dr. Freyre takes particles of the entrails of yellow-fever corpses—for instance, of liver, heart, or brains—puts them in appropriate liquids for cultivation, and of the fourth culture he takes a particle again, and inoculates it. Dr. Carmone claims that the yellow-fever germ is not reproduced in that way, and consequently Dr. Freyre only inoculates broth, etc.

Dr. Carmona has found in all the liquid and solid tissues of yellow-fever patients one and the same microscopical fungus, identical with the "peronospora lutea." He considers that to be the characteristic of yellow fever. The easiest way to get that "peronospora lutea," or rather its "zoosporon," is to take a quantity of urine and to evaporate it. The dry sediment contains the vaccin matter against yellow fever. A minimum of this sediment is diluted in distilled water and injected hypodermically.

Physicians versed in the use of the microscope pretend that the "peronospora lutea" is found in every urine of every body, if it stand a certain time exposed to the air, or if the recipient vessels have not previously been perfectly well cleaned. Your correspondent has no pretension to be a judge in the matter; however, if the "zoosporon" of "peronospora lutea" is not the cause of yellow fever, its introduction in the living might still prove to be a preservative against the terrible scourge.

Several thousand people have been inoculated by Dr. Carmona's method, and experience will soon show whether he has made a mistake or a great discovery.

F. S.

City of Mexico, June 29, 1885.

NEURONYMY.

To the Editor of The Medical Record.

Sir: In the report of the recent meeting of the American Neurological Association in The Record for June 27th, page 713, and in the editorial, "Brain Nomenclature," page 708, the words *neuronomy*, *paronomy*, and *heteronomy* should be *neuronymy*, *paronymy*, and *heteronymy*. There may be room for a difference of opinion or taste as to which of the two forms, ὄνομα, onom, and ὄνυμα, onym, should be used in combination, but the latter occurs in *synonym*, *eponym*, and *paronym*, which are given in English dictionaries, and in *mononym*, *dionym*, etc., recently suggested by Dr. Coues, as well as in my own *organonymy* and *toponymy*. The three words in question are correctly printed on the program of the meeting.

Time failed for the public discussion of my address, but in private conversation with two well-known and progressive members of the Association, one of them expressed a preference for the unchanged Latin names (e.g., *commissura media*), while the other would rather render them into ordinary English (e.g., *middle commissure*) by translation or heteronymy. My mononym for the Latin dionym is *medicommissura* and its English paronym, *medicommissure*, permitting the formation of the adjective *medicommissural*. It will be seen, therefore, that my position is strictly intermediate between the classicalism which may appear pedantic (e.g., *iter a tertio ad quartum ventriculum*), and the vernacularism (heteronymy) which may be undignified (e.g., *worm, body of Luys*, and "*passage from the third to the fourth ventricle*"). I am neither surprised nor disturbed at the reluctance of teachers and writers to change their accustomed modes of expression, but my belief that the English neuronymy of the not far distant future will consist chiefly of mononymic paronyms (English forms of Latin names of a single word each) is certainly not shaken by the incident just mentioned. On the contrary, as a not unhappy mean between two extremes, I am reminded of Lord John Russel, who "knew he was right because all parties found fault with him."

Burt G. Wilder, M.D.

Siasconset, Nantucket, Mass., July 3, 1885.

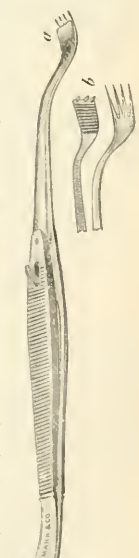
New Instruments.

A NEW TISSUE OR TRACHELORRHAPHY FORCEPS.

By Geo. Cowan, M.D.,

Danville, Ky.

The difficulty of clearing out the angles nicely between the flaps in lacerations of the cervix, so as to bring the planes of incision to their true line of intersection, is a well-recognized one; and no apology to the profession is necessary for inflicting upon its consideration a new instrument in the shape of a tissue forceps. Everyone who has had to operate upon irregularly-shaped, unsymmetrical lacerations, filled with tough cicatricial tissue, has experienced the difficulty of locating and controlling, with a proper degree of precision and ease, the lines of incision with the instruments used for cutting, whether they were the curved scissors or scalpel. I have, therefore, had the Messrs. George Tiemann & Co. construct for my use the tissue-seizing forceps illustrated by the accompanying drawing.



The blades are designed to transfix and then clamp firmly small areas or layers of tissue between their grasp, and at the same time to serve as a mechanical guide which limits and directs the scalpel or scissors in any given direction of dissection. They nest or *spoon together* like a pair of silver forks; one of them having small sharp tines or prongs like those of a common eating fork, while its companion presents a flat surface to its fellow, and is armed with short, sharp, and very small teeth, which interdigitate with the tines or prongs. The method of using it is as follows: The tined blade is first thrust in underneath the tissue to be removed, when the clamping blade is pressed down upon it, and its hold secured by a catch spring and the small teeth, which bury themselves in the tissues.

A scalpel or curved scissors now is made to cut along

under the surface of the tined blade, freeing the instrument from its position where it has been embedded in the tissues, and leaving the separated tissue adhering by one end. Underneath this detached portion the pronged blade can be reinserted as often as necessary, and the whole finally taken off in one continuous layer; or the whole piece may be left at the point of intersection of the opposite side, to be removed by uniting the two planes of dissection at the proper centre. The tissue may in this way be so removed as to make any angle at the pleasure of the operator, and clear of all togs and shreddy bits of tissue which the bistoury or scissors often leave behind. The workmanship is in accordance with the well-known skill and excellence of the manufacturers.

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 19, 1885, to July 25, 1885.

ELBREY, F. W., Captain and Assistant Surgeon. Sick leave of absence further extended four months on surgeon's certificate of disability. S. O. 162, A. G. O., July 17, 1885.

STRONG, NORTON, Captain and Assistant Surgeon. Ordered for temporary field duty with battalion Eighth Cavalry, at Hillsboro, N. M. S. O. 34, Headquarters District of New Mexico, June 27, 1885.

EVERTS, First Lieutenant and Assistant Surgeon. Ordered for duty as Post Surgeon, Benicia Barracks, Cal. S. O. 70, par. 3, Department of California, July 22, 1885. (Modifies par. 2, S. O. 68, c. s., Department of California).

WINNE, C. K., Captain and Assistant Surgeon. Ordered for duty at Benicia Arsenal, Cal. S. O. 70, par. 3 Department California, July 15, 1885. (Modifies par. 2, S. O. 68, c. s., Department of California).

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 25, 1885:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.								
July 18, 1885	0	12	46	1	109	70	0	0
July 25, 1885	0	11	31	4	69	50	3	0
Deaths.								
July 18, 1885	0	3	9	1	21	34	0	0
July 25, 1885	0	3	3	4	18	18	0	0

THE PRESERVATION OF BODIES OF PERSONS DYING FROM ARSENIC POISONING.—With reference to the cases reported under this head (see RECORD May 9th) our correspondent from Lafayette, Ind., writes there was no formation of adipocere, but the bodies were preserved as if injected for dissection.

RETENTION OF URINE.—Dr. Malley recommends an ointment made of one part extract of nux vomica to ten of lard in the treatment of functional retention of urine. A piece the size of the thumb-nail is to be rubbed on the hypogastrium once or twice a day.

SCIENCE, FREE THOUGHT, AND THE BRAIN OF VICTOR HUGO.—In a recent issue *La Tribune Médicale* enters a complaint under this caption against the family of Victor Hugo, because they did not accede to the request made for an examination of the poet's brain. "If ever," the writer says, "a brain ought to have been studied in order to discover and to demonstrate the relations of the organization and structure of the organic substratum to the extent and perfection of its functional activity, that brain was certainly Victor Hugo's. In the case of Gambetta, there was found an exceptional development of the cerebral convolution constituting the organ of spoken language, and," *La Tribune* continues, "what might we not have found as regards the organ of thought and of its expression in the brain of Victor Hugo!" What indeed! We might also, though this did not occur to the writer apparently, have been enabled to locate with more definiteness than at present the organ of self-esteem and of its untiring expression. But with two such finely developed convolutions the difficulty would have been to decide which was thought and which wasn't. "As I was crossing the new iron bridge I met Tim Farley. 'How do you do, Mr. Farley?' sez I. 'How do you do, Mr. Muldoon?' sez he. Sez I, 'I'm not Mr. Muldoon.' Sez he, 'I'm not Mr. Farley.' And we looked at each other again, and bedad it was nayther of us!"

THE WOMEN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY.—A correspondent writes that one of the recent graduates of this college, while on a visit in a Western State, was called to see a case of retained placenta. When she arrived she found the attending physician, a regular practitioner, and a man of some age, sitting by the bed fanning the patient. The young woman's opinion being asked, she said she would try Crédé's method of expressing the placenta, and failing in this, she would introduce her hand and remove it. The physician replied that the patient had lost too much blood and was, in his opinion, too much exhausted to bear the operation, but gave his consent, finally, to the trial, and suggested that the visitor should do it, as her hand was smaller. This the young graduate did, and, finding the placenta attached, removed it and secured uterine contractions. The patient did well. Another young graduate, of one week's standing, was called unexpectedly to a case attended by a homœopathic physician. The patient was unconscious and pulseless. Examination showed that the head was engaged, but the cervix uteri was separated from the body through half its extent. The young woman at once divided the cervical ring with scissors, applied the forceps, and delivered the child. The patient made a good recovery. These cases speak well for the coolness and quick wit of these young graduates, and also for the excellence of the instruction imparted to the students of the Women's Medical College of this city.

NOVEL FRAUD.—A case which well exemplifies the advisability of medical men viewing the body before giving a certificate of the cause of death is reported from Flash, near Buxton. A man, named William Mellor, of that place, lately perpetrated a most curious imposition. Having been ill and attended by a medical man, he, upon recovery, shaved off his whiskers and beard, and otherwise so altered his appearance as to induce the surgeon to believe that he was William Mellor's brother, and that the sick man was dead. Having obtained a certificate, he registered his own death, and drew the burial-money from a Foresters' lodge. Upon the discovery of the fraud, he decamped.—*Lancet.*

THE DIAGNOSIS OF SUBMERSION DURING LIFE.—The Paris correspondent of the *Lancet* writes, asking us to correct a mistranslation of his in an item on the above subject published in THE MEDICAL RECORD of May 16th. The word "*mousse*" should be rendered "froth," instead of "moss."

The Medical Record

Original Articles.

ASTHMA.

By J. MILNER FOTHERGILL, M.D. EDIN., HON. M.D. RUSH MED. COLL., ILL.

PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST (VICTORIA PARK).

ASTHMA is a term applied to totally different conditions. Its meaning is changing, hence the confusion. According to Dr. Johnson, in 1824, asthma is "a frequent difficult and short respiration." According to Dr. Nuttall, 1880, asthma is "a chronic, intermittent disorder of respiration; the term is also sometimes applied to any chronic difficulty of breathing." Of old the term had no definite meaning, covering the ground now embraced by "dyspnœa." At the present time a medical teacher uses the word "asthma" only when he speaks of a condition of hard breathing brought about by spasm of the circular muscular fibres of the bronchiæ. A lay person will use it in Dr. Nuttall's second sense "any chronic difficulty of breathing," as in emphysema, pulmonary congestion from a mitral lesion, or any other cause of dyspnœa.

Spasmodic or bronchial asthma is an affection which comes on suddenly, and varies in intensity and duration, from a mere thickness of the wind to a terrible choking, from a few minutes to several days. When an asthmatic attack is on the patient's energies are bent to the act of breathing. There is a look of earnestness upon the features, which are pale and clammy, or even livid, according to circumstances. The shoulders are fixed so as to get the advantage of the pectoral muscles as accessory respiratory muscles. Very commonly the individual is spare and of the neurosal diathesis. After repeated attacks the shoulder-tips stand forward more angular than normal, so that the lean asthmatic may be recognized in the streets. A girl of ten on whom these characters are already stamped came under notice while writing this paper. An asthmatic, like a dyspeptic, is often an intelligent person; both having usually highly developed nervous systems.

At other times asthma is found with the truly emphysematous individual with the barrel-shaped chest, and a high-colored complexion; a matter which will be referred to again later on.

The circumstances under which spasm of the bronchial muscular fibres is set up vary. With the susceptible nervous system it may have as its causal relations some mental disturbance, as emotion even; or in a woman the perturbation of the catamenia may, and commonly does, excite it. Probably this aspect of asthma as a true neurosis has not been sufficiently considered. Then it has relations to food; and an attack may follow a good dinner. The late Hyde Salter pointed out that when asthma has such causal relation it is apt to come on in the small hours of the morning; and that if the asthmatic will sit up awake till the hour is past, he can escape the attack, which certainly comes on if he allows the hour of its approach to find him asleep. In one asthmatic patient a non-nitrogenized dietary is enforced by her asthma; akreophagy alone renders life tolerable. As we are seeing gouty neuroses of the heart of various kinds so gouty disorders of the respiration are looming up. In one case of sudden thick wind in a gouty man the attack, after lasting six-and-thirty hours, passed off with a sharp bilious purging. The older writers spoke of "gouty asthma," indeed. Of course, all know its relation to the inhalation of irritant matters, mechanical or chemical. In such cases organic changes in the lung are set up in time. Needle-grinders, masons who hew fine stone, like that of the Edinburgh quarries, potters who inhale the fine dust of biscuit-ware, millers, bakers, feather-dresses, millstone pickers, all, indeed, who inhale fine particles, suffer from asthma; and in time bronchopneumonia, which is fatal if they do not change their occupation.

There are other relations, however, of bronchial asthma which may profitably be considered. In persons of a highly developed nervous system the starting-point of asthma is commonly a cold. The bronchial lining membrane is so made irritable, with the consequence of this condition in turn starting bronchial spasm. There is some obstruction to the breathing in consequence of the swollen mucous membrane, which measurably lessens the lumen or calibre of the finer bronchial tubes. Superimposed upon this comes the spasm of the bronchial muscular fibres, and then an acute condition of "asthma" is set up. Such is the natural history of attacks of asthma in some very charming young women.

The recognition of the causal relations of an asthmatic attack clears up the line of treatment to be adopted. In pure primary spasm the fuming remedies are of service. When secondary to bronchial irritation then inhalations of medicated vapor are more likely to be of service. In the latter case the treatment of the first stage of bronchitis (which will be considered in the article treating of bronchitis) is also indicated. Such, then, are the ordinary relations of spasmodic asthma in persons of the neurosal diathesis.

Persons of a totally different build and physique are subject to truly asthmatic attacks, which follow upon chronic bronchitis and emphysema. In these cases, along with sacculated conditions of some portions of the air-tubes are found other areas of thickened muscular tissue; and in these tracts of muscular hypertrophy spasm is common. Habitually "asthmatic" (in the popular sense), they are liable to attacks of "asthma" to boot—engrafted on the chronic dyspnœa, and causing acute distress. Here the treatment of the attack is that of spasmodic asthma—however brought about.

There are two conditions under which asthma *spasmodica* is simulated. There is pulmonary congestion from disease of the heart; either a mitral lesion, a failing left ventricle, or dilatation, or temporary distention of the right heart. Wherever the blood-flow through the lesser or pulmonic circulation is obstructed the condition is one liable to sudden aggravation with acute distention of the right ventricle. Such a condition is commonly spoken of as "cardiac asthma"—a not inappropriate term.

The other is flatulence. When there is a sudden development of gas in the intestines, the diaphragm can not descend, and the acute difficulty of breathing is experienced. Whenever from any cause (pulmonary or cardiac, or, indeed, hepatic) there is venous fulness of the portal circulation, and with that venous congestion of the mucous membrane of the alimentary tract, gas is given off, often in considerable quantities. In old-standing cardiac disease, in old-standing disease of the respiratory organs, and especially in emphysematous conditions, such sudden evolution of gas is common; and when elas-

tic gas interferes with the descent of the diaphragm and presses upon the right chamber of the heart, acute distress is experienced. The sufferer will often call such an attack "asthma," and can find dictionary warrant for his use of the term. In chronic emphysema the diaphragm is the great matter in inspiration; and when it cannot descend, very acute distress and breathlessness result. No wonder these sufferers speak of "the wind" with considerable empressment!

When the physician is called in to a case of "asthma" his first business is to differentiate the particular case before him, and refer it to its proper class. So soon as this is done the treatment suggests itself naturally therefrom.

In "hay asthma" the existing cause is the pollen of certain plants, and specially the anthoxanthum odoratum. Here avoidance of the cause does away with the whole train of results. If the sufferer can manage it, a sea-voyage at the season would save him from his asthma. How far "hay asthma" is amenable to any line of treatment here to be suggested the writer can not say; it is not a malady grave or serious enough to come, or be brought under his notice.

Primary spasmodic, or bronchial asthma, in persons of neurosal temperament involves two lines of assault. There is the treatment of the attack and the treatment of the interval. When the attack is on, then something which will relax the muscular spasm is indicated. For the last fumes are in vogue. Nitre or touch-paper (brown paper soaked in a strong solution of saltpetre) may be burned. Himrod's powder, the solace of the late Lord Beaconsfield, is held in high repute by sundry well-known physicians liable to attacks of asthma. Cigars de Jay are the favorite resort of others. With some tobacco is sufficient. With others cigarettes of datura tatula, or datura stramonium are found serviceable. With most asthmatics these "fuming" remedies give relief—more or less complete; but with others (fortunately for them but a small class) these fuming remedies are useless and inoperative. An emetic is the only measure of any service. In one case where the lean of animals has to be eschewed entirely, on account of the asthma set up by any indulgence therein, an emetic or a bad night are the alternatives. A scruple of ipecacuanha powder at bedtime ensures a fairly unbroken night; but this is a terrible alternative. Food has to be taken early in the day, otherwise the emetic is impotent to give relief. It is a life of misery, yet borne courageously. Then local applications by means of vapors (produced by the spray) give relief in some cases. Sulphurous acid, nitrate of silver, and other medicaments have been tried with advantage. At one time lobelia inflata was a fashionable remedy in asthmatic attacks, and is certainly worth a trial in many cases, though a nauseous remedy.

Then as to the treatment of the interval. First and foremost comes belladonna, a potent stimulant to the respiratory centre, while at the same time it relaxes all circular muscular fibre (this statement is made deliberately). Then ipecacuanha is good, and the two may be combined in pill advantageously. Arsenic often gives good results. Of course the vegetable tonics of all kinds and hæmatics suggest themselves; it is unnecessary to run over the gamut of tonics. Locality is a great matter. In one place the asthmatic is at ease; in other places residence is one prolonged agony. Change of locality is a matter to be discussed in all severe asthma. In catamenial asthma sometimes it is enough to give belladonna, or bromide of ammonium, as the case may be, at the flux, with some appropriate treatment in the interval. In asthma caused by the inhalation of irritants change of occupation may be essential to relief. The grinder or mason may enter the police force or enlist. Then there is asthma secondary to an irritable congested condition of the bronchial lining membrane, catarrhal asthma. Here inhalations of steam, plain, or medicated, give great relief. To relax the turgid vascular mucous membrane (see article on Bronchitis) is to give relief. It is usually a persistent first stage of bronchitis, of a dry membrane with arrested secretion, which starts up the spasm. Fuming remedies here usually rather aggravate than allay the condition. Hence the importance of a correct diagnosis as to the causation of the spasmodic condition when called in to a case of spasmodic asthma. How far a chronic irritable condition of the bronchial lining membrane underlies recurrent asthma is a subject needing further investigation; it seems probable enough. That such a condition should exist in persons of the neurosal diathesis—the chosen subjects of asthma—is in harmony with one's experience of such persons; a distinct class, having features of its own. Asthma, neuralgia, migraine, dyspepsia, neurosal skin affections, as herpes, in women dysmenorrhœa and disturbances called hysterical, are the maladies which these "neurotics" step into as part of their inheritance.

Cardiac asthma carries with it its own appropriate treatment. Here the matter par excellence is the distention of the right ventricle, threatening paralysis in diastole. To prevent this untoward event two measures suggest themselves. One is to relieve the engorged venous system and right heart by venesection; and certainly in all grave cases the lancet should be brought on the scene. Relief being so afforded the distended muscular chamber can once more contract upon its contents. The other is to flog on the heart by the external application of heat, as hot poultices to the front of the chest, or hot water in an india-rubber bottle (as that used to warm the bed), and by stimulants. Alcohol (in unstinted quantities if need be), ammonia, digitalis, strychnia, belladonna, all are useful. Sometimes alcohol is the only measure at hand, and must be used freely. In a lone farm-house the whiskey-bottle may be the only available medicine. To push stimulants and to bleed at one and the same time are not antagonistic measures; and the combination is indicated in severe cases.

In cases presumably of gouty origin a mercurial followed by a sharp dose of laxative medicine is the first step to take. Indeed, in other cases experience may have taught the sufferer that prompt action upon the liver will commonly avert or abort the attack. Asthma, like epilepsy, is in some cases preceded by the free indulgence of the palate or neglect of the bowels. Attention to the general health and the correction of everything amiss are often as essential as a complete equipment of fuming remedies for an asthmatic.

Asthma (or dyspnœa) of flatulent origin is a very common occurrence with many persons, and specially invalids. Here, of course, the fuming remedies are useless. Emetics may give relief. Carminatives certainly do. Essence of ginger or peppermint, cayenne in pill with breadcrumb, sal volatile, all are good. But perhaps best of all is the old Scotch wife's plan (advocated eloquently by the late Sir James Young Simpson, Bart.), viz., to put as much black pepper as will lie on a sixpence or a dime into a teacup, and fill half up with hot water; then drink all. This can be repeated at short intervals if necessary.

It is quite clear that in each and every case of asthma, indeed, perhaps every attack, no stone should be left unturned, and every association should be weighed in relation to it. Attention to the causation will guide the treatment in one case; the experience of the afflicted individual at other times is invaluable in giving direction to our therapeutic endeavors. Asthma is a complex matter, with different pathological conditions (speaking of the term in its broadest sense) and varied clinical features. Equally capricious is the malady in its amenability to remedial measures; as variable as a coquette with her favors. What suits one case utterly fails with another—to all intents and purposes as like it as two shrimps are to each other. No one can tell why or wherefore! The locality which is preservative against asthma with one may provoke it with another asthmatic. "A gentleman, mentioned by Dr. Bree, could never sleep in the town of Kilkenny, in Ireland, without being

attacked by asthma; and Lord Ormond could never sleep out of the same place without suffering in the same way" (Forbes).

But, granting all this, it is possible to so approach most cases of asthma as to elicit its associations, and on a correct and ample diagnosis to assail it on a distinct principle, and so to cope with it successfully, provided sufficient pains be taken in each case.

EXTRACTION OF A LENS, DISLOCATED INTO THE VITREOUS, WITH THE AID OF DR. C. R. AGNEW'S BIDENT.[1]

By DAVID WEBSTER, M.D.,

PROFESSOR OF OPHTHALMOLOGY IN THE NEW YORK POLYCLINIC; SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL, NEW YORK, ETC.

James B——, aged sixty-eight, a native of Scotland, salesman in a lumber-yard, of correct habits and of good general health, received a blow upon his right eye from a chip of wood which he was chopping some time in November, 1883. There was immediate loss of vision, with severe pain, and considerable ecchymosis of the lids followed. Under the care of his family physician the pain and inflammatory symptoms subsided, but the disturbance of vision remained. This led him to seek expert advice, and in February, 1884, some three months after the injury, he consulted Dr. C. R. Agnew at the College of Physicians and Surgeons. He was found to have a dislocated lens, but as the eye was "quiet," and as the vision of the other eye was $\frac{2}{3}\frac{0}{0}$, no operative interference was advised. He visited the clinic at the Manhattan Eye and Ear Hospital a few times with like result. From that time nothing noteworthy in his case occurred, except some impairment of the sight of his left eye from incipient cataract, until Friday, May 1, 1885, when he awoke before daylight with a severe pain in and around his right eye. He was, at the same time, attacked with cramps in the stomach and vomiting, which continued through the forenoon. On looking at his eye by means of a mirror he found that it was bloodshot, and that the color of the pupil had changed from black to white. In the evening of that day he was seen by Dr. Neil J. Hepburn, Assistant Surgeon to the Manhattan Eye and Ear Hospital, and to him I am indebted for careful notes of the case. Dr. Hepburn found a cataractous lens incarcerated in the pupil, partly in the vitreous and party in the anterior chamber. He noted extreme ciliary injection and increased tension, with vision reduced to perception of light. He applied a four per cent. solution of cocaine hydrochlorate freely several times, at intervals of a few minutes, but this had no effect in relieving the pain. He then resorted to the use of the sulphate of atropia, a solution of four grains to the ounce, which gave considerable relief, but which did not release the lens from the grasp of the pupil during the time that he remained with the patient. The use of atropia was continued, at regular intervals, until I saw the patient the next day at 3.45 P.M., along with Dr. Hepburn and Dr. M. Donnelly. The lens had, by that time, become disengaged from the pupil, and was lying loose in the vitreous humor, a portion of its periphery presenting at the lower border of the pupil. On the slightest movement of the eye it floated about freely, appearing to have no attachment in any direction. The pain had mostly passed away, and the tension of the globe was nearly normal. The eye was still very red, however, and the vision had not risen above perception of light.

Having decided to attempt the extraction of the dislocated lens, a four per cent. solution of cocaine hydrochlorate was dropped into the eye half a dozen times at intervals of a minute or two, the eyelids were separated by a Graefe's speculum and the conjunctiva of the upper part of the eyeball was seized with fixation forceps in order to steady the eye. Dr. Agnew's bident was then passed through the temporal side of the eye-wall, the points of puncture being about three millimetres back of the sclero-corneal junction, and was swept around back of the floating lens, which was easily pressed forward into the anterior chamber and against the cornea, by depressing the handle of the instrument and thus elevating its points. The bident was then pressed forward and made to transfix the nasal wall of the eye, the points of counter-puncture being about two millimetres from the limbus corneæ.

The lens being thus safely secured in the anterior chamber, I made, with a Graefe's knife, an incision downward of about the same size and position as in ordinary cases of cataract extraction. I then tried to pass a wire spoon between the lens and the bident but failed to do so because the latter had been pressed too firmly against the former before transfixing the opposite wall of the eye. The central portion of the lens evidently protruded backward between the prongs of the instrument. I therefore withdrew the bident, and the lens, remaining where the bident had placed it, because adherent to the cornea, was removed with the spoon without difficulty. The speculum was quickly removed, so that only a few drops of vitreous escaped. A flannel bandage, with absorbent cotton, covered with a black silk mask, constituted the dressing. Dr. Hepburn took charge of the patient and I did not see him again until after his recovery.

The bandage was removed on the fourth day, and a drop of a four-grain solution of eserine was instilled to draw the iris away from the wound. The eye was opened and carefully inspected on May 9th, seven days after the operation. The wound had healed, and there was an adhesion of the iris at its outer extremity. The patient easily counted fingers with the eye, although some lens-matter still remained in the pupil. At no time after the operation was there any pain. The lens-matter gradually settled down and disappeared by absorption, while by the use of eserine the synechia became so attenuated and stretched that the pupil was nearly circular.

June 15th.—R. V. $= \frac{6}{2\,0\,0}$, made $\frac{2\,0}{2\,0\,0}$ with $+ \frac{1}{4\frac{1}{2}}$; L. V. $= \frac{2\,0}{4\,0}$, made $\frac{2\,0}{4\,0}$ with $+ \frac{1}{3\,6}$. The patient has been attending to his business since June 1st.

July 13th.—R. V. $= \frac{2\,0}{1\,0\,0}$, with $+ \frac{1}{4\frac{1}{5}}$. So far as my observation goes this case is unique. Here we have a dislocated crystalline lens, which has been ploughing about through the vitreous for over a year, and finally becoming accidentally incarcerated in the pupil, and setting up a glaucomatous inflammation, threatening the destruction of the eye, removed with very little difficulty, and the eye saved with vision sufficient to rank as a "success" after an ordinary cataract extraction. Before the invention of the bident such an eye would probably have been enucleated for the relief of pain and to prevent possible sympathetic inflammation. Or perhaps an iridectomy or a paracentesis would have been performed, leaving the dislocated lens in the eye, with all the conditions necessary to repeated attacks of inflammation, leading possibly to total blindness. With the bident I believe many an eye will be saved which, without it, would have been inevitably lost. It may not be applicable to all cases of dislocated lenses. I certainly should not use it where the lens is already dislocated into the anterior chamber, or even where the dislocation was only partial, but in all cases where the lens is floating about in the vitreous, and can be brought into view, I think the instrument may be used with advantage. Without the bident I do not think it is always possible, even when the dislocated lens can be plainly seen, to remove it from the eye, even with great loss of vitreous. If a lens, becoming dislocated during the initial steps of an ordinary cataract extraction, sometimes disappears in the depths of an eye, and cannot be fished out with hook or spoon by the most expert operator, how much more liable is such an accident to occur in a case where the lens is already loose in the vitreous. But if with the

[1] Read before the American Ophthalmological Society, July 15, 1885.

bident you press the lens into the anterior chamber and hold it there, you are not only sure of getting it out of the eye, but its presence acts as a kind of a plug to the pupil, preventing escape of vitreous. The objection to wounding the ciliary body in this way I do not consider a grave one. The clean punctured wounds heal without much secondary cicatricial contraction, and, in the two cases in which I have seen it used, have left no visible scar. Those who have practised "Hancock's operation" for glaucoma, which is essentially an incised wound of the ciliary body, say they have never seen sympathetic inflammation result from it.

I shall close this paper with citations from two of our well-known text-books on the eye.

"If the lens is completely dislocated into the vitreous humor, and is setting up no disturbance, it is wiser not to interfere. But if inflammatory complications arise, or the sight is much impaired by the lens floating about across the pupil when the eye is moved, it will be best to remove it. . . . The operation is, however, very dangerous, for a considerable amount of fluid vitreous will be lost, and severe irido-choroiditis, with subsequent atrophy of the globe, may supervene" (Wells).

"The removal of the lens is especially indicated in cases in which inflammatory symptoms have already appeared. Unfortunately, the removal of the lens from the vitreous involves so great a loss of that fluid, while the difficulty in extracting the lens is so great, that the operation can hardly be said, at present, to come within the sphere of practical surgery, and it is better in such a case to enucleate the eye" (Juler).

THE PULLEY MODIFICATION OF HIS LIMITING TENOTOMY AND ADVANCEMENT OF THE RECTUS OPERATION.

With a Report of a Case of Section and one of Exsection of the Rectus.

By A. E. PRINCE, M.D.,

CONSULTING SURGEON TO STATE INSTITUTIONS FOR THE EDUCATION OF THE DEAF AND DUMB AND BLIND, JACKSONVILLE, ILL.

In the St. Louis *Medical and Surgical Journal*, June, 1881, subsequently in H. D. Noyes' "Diseases of the Eye," appeared the publication of my method of advancing the rectus for the correction of extreme degrees of strabismus and of affording a safeguard against the danger of

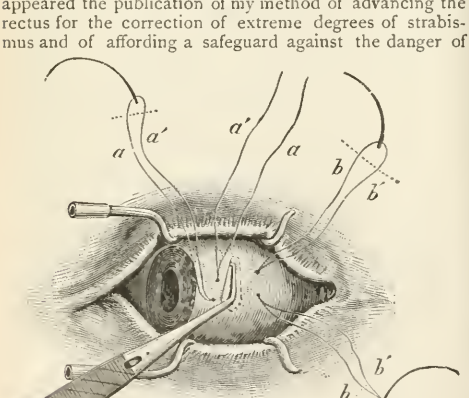

Fig. 1.

over-correction in moderate and minimum degrees of deviation. The advantage then claimed over other methods, and since that time personally acknowledged by a number of careful operators, was twofold: First, that of avoiding the tendency on the part of the stitch to *split the theca* of the rectus, allowing it to retract, thus compromising the result of the operation; second, a desideratum long felt, but not heretofore attained, viz., that of enabling the operator to *modify the effect* after several hours, when recovery of the elastic tension and muscular contractility shall have occurred.

By the *double loop suture* (see Fig. 1) an attempt to gain both of these advantages was made. As to the first of them, both in my experience before publication and during the past three years, and also in the use of the operation in the New York Eye and Ear Infirmary, its results have been satisfactory, when the suture has been firmly secured to the *sclera*.

Not so much has been substantiated by additional experience as to the universal success of the second advantage claimed. In tying suture *a*, after twisting both branches together, with suture *b*, similarly treated, four threads form the knot, which renders the manipulation of tightening or loosening more difficult and less precise

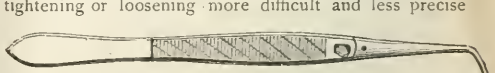

Fig. 2.

than when but two threads are employed. In my present operation, to be described below, this difficulty, of modifying the effect by changing the tension of the suture, is overcome by forming a loop or pulley with *a*, through which passes one branch of suture *b* (see Sec. 7).

The formation of this suture and its action will be perfectly understood by reference to the following brief description of the operation:

Operation.—1. The patient being cocainized, a medium-sized antiseptic silk suture, *a a*, is introduced into the *dense* superficial scleral tissue[1] two millimetres from the corneal margin.[2]

2. The conjunctiva and Tenon's capsule are opened in the usual manner.

3. One branch of the *fixation advancement forceps* is introduced and the remaining branch closed down on the conjunctiva, grasping the tendon of the rectus, which is now to be separated from the sclera with the strabismus scissors.

4. The muscle having been elevated by the forceps, both needles of the double loop suture *b b'* are introduced from beneath through Tenon's capsule, muscle, and conjunctiva, including the middle portion of the rectus, sufficiently far back to allow for the portion to be excised. This step will be further facilitated by the use of the advancement needle illustrated below.

5. The forceps still remaining elevated, the belly of the muscle is severed by the scissors two mm. on the corneal side of the suture *b b'*.

6. The needles being cut away, four independent sutures are formed, viz., *a*, *a'*, *b*, and *b'*.

7. Ignoring *a'* and *b'*, one branch of suture *b* is crossed over suture *a*, both branches of which are now tied down enclosing *b* in a loop or pulley.

8. Both branches of *b* are now tied together, and it will become apparent that *in proportion as they are tightened* over the pulley formed by *a* will the cut end of the rectus be approximated to the insertion of the tendon, simultaneously closing the conjunctival gap.

9. A bow-knot is applied, by loosening which the effect may be modified, after several hours. If all is then satisfactory, sutures *a'* and *b'*, which are reserve sutures to be used in case of entanglement, are now withdrawn. The eye is washed and dressed with absorbent cotton kept wet with a one-half per cent.

[1] A theoretical objection has been made that the suture *a a'* will not hold, since it involves so little tissue, as compared with that of Wecker, Graefe, Agnew, and others. This objection is answered by emphasis placed on the words *dense superficial scleral tissue* (Sec. 1). After introducing the suture which should be done in exactly the same manner as Knapp introduces a guy into the sclera for increasing the effect of an internal tenotomy), its security should be tested before proceeding further.

[2] The difficulty of securing a needle both sharp and slender which may be introduced into its dense superficial scleral tissue without much resistance has been overcome by those of Liier, Paris, which have hitherto been used. They have been successfully duplicated and will be furnished by Tiemann—needle No. 25.

aqueous solution of acid. carbol. pur., plus ten per cent. of glycerine.

The stitches may be removed on the fourth day. Usually, the tendon of the opposite rectus is divided as a preliminary step. In case of over-correction following a faulty operation in which the belly of the rectus, in place of the tendon, has been divided, it is impracticable, if of long standing, to advance the receded muscle, in which case the opposing muscle is to be divided back of its transit through the capsule and the advancement stitch introduced in the opposite conjunctival tissue, as in the first of the exceptional cases described below. In case of complete paralysis of either rectus, the opposing muscle should be exsected or divided as far as possible back of the capsule of Tenon, inserting the advancement stitch in the opposite tissue should the tendency to deviate still continue.

Limiting Tenotomy Suture.—The substitution of the pulley (Sec. 7) in place of the original form constitutes an especially safe and effective procedure to afford security against the danger of over-correction, first, in those cases in which one desires to produce extreme effect by extensive division of the capsule; and, second, in the minimum degrees of deviation which compromise comfortable binocular vision. In these cases single sutures are used, and *b* is introduced

Fig. 3.

further forward, simply dipping into and out of the muscle with a sharply curved needle, which is made for me by Tiemann.[1]

Care being exercised to exert no traction on the hook, thus avoiding temporary paresis and diminishing the

Fig. 4.

danger of subsequent deviation, both conjunctiva and capsule are divided, together with the tendon, after which the effect is limited by gradually tightening suture *b* over pulley *a*, as in the advancement operation, until the symmetric effect is perfect, or better, when possible, until vertical double images are produced by a prism with horizontal axis.

Case I. *Over-correction of internal strabismus followed by extreme external deviation of both eyes with limited motion.*—The following case is an illustration of what is fortunately much less common now than twenty years ago, when the importance of the relation of the anatomy of the capsule of Tenon to the operation of strabismus was seldom recognized by the numerous travelling so-called oculists and general surgeons, who, without the knowledge of refraction and its relation to strabismus so prominently brought before the profession by Donders in his "Anomalies of Refraction," conceived no other essential for a successful operation than that of "hooking up the muscle and cutting it off." The trail of these empirical peripatetic strabotomists is marked by such cases as that of Mr. Barney B——, of Sidney, Ill., aged forty-three, who consulted me April 24, 1883, and whose experience will be appreciated by reference to the accompanying photo-engraving, in which effort has been made to preserve the exact appearance which he presented with the following history: Twenty-three years ago his father entertained a guest over night, who made it his business to travel the country and straighten cross-eyes. The young man having an internal squint, it was considered a rare fortune thus accidentally to have presented an opportunity which might never occur again, for they were poor, and he was willing to straighten both eyes for his lodging and $2.50. A week later, when Dr. Strabotomist was pursuing his calling many miles away, it was considered safe to expose the eyes to the light, when the condition was revealed which has suffered no material change since that time.

Both eyes were deviated extremely outward, measuring with Snellen and Landolt's method[1] 50° in the right eye, of which a portion of the iris was concealed under the external canthus and the lateral motion limited to 10°. With H. = 1.5 D. (or $\frac{1}{24}$) corrected, V. = $\frac{20}{40}$. In the case of the left eye external deviation was 40°, lateral motion 15°, H. = 1.5 D., V. = $\frac{20}{40}$. Direct vision was very imperfect, but by turning the head to bring objects in the visual axis of either eye he could see tolerably well. As he was very anxious to have an effort made for which I knew no precedent, I explained to him that I would attempt as bad an operation on the external muscles as his $2.50 operation had been on the internal muscles, and that I hoped by the aid of a stitch to be able to draw the eyes over and hold them in position, and to effect a parallelism of the eyes, so that he would look well and have direct vision, but that he must not expect to have lateral motion, for, with the lateral rectal attachments of both eyes destroyed, he must be satisfied if they were simply straight. With this understanding, the operation was undertaken. A lateral incision was made above each external rectus and the hook introduced far back, exposing the muscle, which was divided outside the capsule. An internal advancement suture was placed in each eye, and no deviation made from the usual after-treatment. The weak carbolic acid wash was acceptable to the patient, and prevented inflammation. No pain followed the operation, which was done under ether. On the fourth day there was a deviation of 5° inward.

The most gratifying and at the same time *surprising* fact, especially worthy of note, was the *unpredicted amount of lateral motion*, which in the right eye amounted to 40°, and in the left to 45°. As this is the only case of the kind known to me, I am unable to compare it with reference to this point, and the theoretic explanation is offered that both external and internal recti

[1] This needle will be found greatly to facilitate the introduction of suture *b b'*, when the tendon has retracted with the capsule. The correction is then made without difficulty after dividing the conjunctiva and slipping the needle as a strabismus hook between the capsule and the sclera when a half-rotation with depression of the handle brings the point out through the conjunctiva. The short end of the thread is then caught with toothed forceps and the point retracted. Without removing the thread the point is reintroduced and the thread caught on the same side of the needle as before, when the withdrawal of the needle leaves the suture *b b'* in position, exercising a firm hold on the muscle, which may then be brought forward and secured. This needle will be sent on approval by Geo. Tiemann & Co., when its action will become manifest. By its curve also the co-apeation of the conjunctival edges after enucleation, as well as the introduction of the sutures in canthoplasty, is facilitated.

[1] Bestimmung des Schielens. Snellen u. Landolt. Handbuch der Augenheilkunde. Graefe and Saemisch, vol. iii., p. 235.

formed a union with the posterior hemisphere of the capsule, for it is scarcely probable that so great an amplitude of motion could be accomplished by the recti muscles acting alone on the orbital cellular tissue. An application of this theoretical view will appear in the treatment of the following case. The above case being of unusual interest, the result, photographed before his departure, ten days after the operation, completes a unique history, with the good result continuing to exist to the present time.

Case II.—Mr. T. A. D——, Oneida, N. Y., aged about thirty years, presented himself at the College of Physicians and Surgeons, New York, with a condition of complete paralysis of the external rectus of the left eye, following a railroad accident twelve years since. In the collision his head was jammed between two cars. The recovery from the injury was rapid, leaving no other effects than an extreme internal deviation with partial concealment of the iris. Some years since an unsuccessful operation was performed. Tested at the College and at the Manhattan Eye and Ear Infirmary, several days later: V. = counts fingers at 6 inches; internal deviation about 50°; absolutely no motion.

Fig. 5.

Having the good fortune to be in the city, the courtesy of Dr. Webster was extended in an invitation to demonstrate my method of advancement, on the following day, at the Manhattan Eye and Ear Infirmary. From the experience of the case related above I considered that a simple section of the muscle back of the capsule would be insufficient; that an attachment to the posterior hemisphere would probably occur, and reproduce a partial internal deviation. Determination was therefore made to exsect the muscle as far back as possible to avoid this danger, the intention being to destroy the efficiency of the internal rectus. Under the influence of cocaine, the globe was rotated, with fixation forceps, as far to the temporal side as the contracted and hypertrophied muscle would permit, in order to allow of the introduction of the hook. Having no reliable advancement forceps, a thread was passed around the muscle after Agnew's method. Parallel lateral incisions were made above and below the muscle, which was drawn out by the continued traction of the hook, and divided, at the remotest visible point, and the anterior portion was then separated from the sclera. An exsection and advancement of the external rectus was made, and the eye kept moist with saturated solution of boric acid, on cotton, a favorite and efficient remedy of Dr. Webster and other members of the Infirmary staff. No pain or special elevation of temperature followed the operation. The stitches were removed on the fourth day. The eye was perfectly straight. No exophthalmos or unnatural appearance except the absence of lateral motion. After a week V. = $\frac{20}{30}$; in a direct line has binocular fixation, but lateral motion of the head either way causes diplopia. He left the hospital satisfied, with still some little ecchymosis, rapidly absorbing.

Taken in connection, we conceive the above cases to have sufficient interest and value to justify their publication, inasmuch as they initiate a discrimination between the indications for section and exsection of the belly of the rectus.

UPON THE ORIGIN OF TUMORS AND CANCERS.[1]

By THEODORE A. McGRAW, M.D.,

DETROIT, MICH.

Since the publication of Virchow's "Cellular Pathology" and his great work on "Morbid Tumors," the current of professional public opinion has run almost altogether in favor of the dogma of the local origin of tumors and cancers. It cannot be denied that the arguments in its support seem at first sight to be very conclusive. A cancer of the breast begins as an apparently local trouble, it grows and spreads, and new lumps form in the neighborhood of the primary tumor. The neighboring lymphatic glands become next affected, and afterward those which are more distant. Then metastatic tumors form in distant parts of the body, and finally a cachexia develops which soon ends in death. Or a boy receives a blow in the eye, from the effects of which it becomes inflamed. The inflammation, however, does not pursue its usual course but develops a sarcoma, which soon kills the patient. In these and in most cases of tumors the influence of location and local irritation is so manifest as not to be mistaken. The progress of the disease, whenever it assumes a general character, is apparently from a local lesion to a constitutional infection, and it is natural for practical surgeons to incline to a theory which not only promises possibilities of cure, but also seems well sustained by the facts of the case and the results of treatment. For it is certain that the plans of treatment based upon this hypothesis have had far greater success than those established when it was universally believed that cancer was primarily constitutional—infecting the blood from the very beginning. The quick and thorough excision of every malignant growth has saved thousands of lives, and every surgeon of experience can now show cases in which tumors of undoubted malignancy have been so successfully removed that no recurrence has taken place after many years; and yet, notwithstanding this vindication which the theory has received from actual practice, there arises certain arguments which make us doubt sometimes whether one's ancestors were altogether wrong, and whether, after all, besides the causes which influence its production, there must not be behind some abnormal constitutional condition, without which neither cancer nor tumor could arise to vex the body. It is to call attention again to this constitutional something that I venture to write this paper, even at the risk of shocking that pathological faith in the localization of this kind of disease which has become nearly universal in the profession. It is my purpose not to deny the influence of local causes in the production of neoplasms, for I firmly believe in them as partial factors, but I insist upon the recognition of those other groups of facts which demonstrate to my mind beyond doubt that the theory of local origin is insufficient to account for all the phenomena, and that cancers and tumors arise from the combined influence of constitutional as well as local conditions.

[1] Abstract of paper read before the Michigan State Medical Society.

I find it necessary, however, at the very outset, to say that I do not regard the word "constitutional" as synonymous with "pertaining to the blood." It is very curious, that with full and undoubted faith in the doctrines of a solider pathology, the profession have not been able to divest themselves of certain conceptions which are consistent only with systems of humoral pathology. The most persistent of these fancies is the inborn belief that a constitutional dyscrasia must reside in the blood. If we ask a surgeon to-day whether a cancer is primarily constitutional, he will answer, "No; it appears first in the solid tissues, and the blood becomes only secondarily affected; therefore, cancer is of local origin."

Now it may be a question whether any disease has a constitutional origin in the sense understood by our fathers, and it has seemed to me that an unnecessary confusion has been caused by this misunderstanding of the word "constitutional." Unless we would abolish it altogether—and no one would think of doing that—we must give it a meaning more in consonance with our prevailing theories. There are, in fact, very many possible constitutional conditions in which the blood itself would be affected only secondarily, if at all, and which must be recognized as possible factors in the production of disease. Of these we may instance, first, any general degeneration of the blood or lymphatic vessels. When we think of these vessels in their actual relations, how they penetrate into nearly all tissue, how all tissue depends upon them for their nutritive supply, and how they govern all of the processes of inflammation and repair, we must admit that any disease affecting them generally, must exert a positively deleterious influence upon the whole animal economy.

The same is true of the vaso-motor nerves, which have an immense though not yet well-understood or sharply-defined influence upon the nutrition of the higher animals. Certain glands, too, have their relations with the whole body, so vital in kind, that even a disturbance of their functions may be regarded as a constitutional disease.

Let us suppose that we should find, as a matter of fact, that cancer was caused by some abnormal condition of the kidneys or liver. Should we not say that it was of constitutional origin?

The fact that the original disease—that of the kidneys or liver—was local would not affect the state of the case as regards the cancer, for that would depend upon a condition common to the whole body. The same would be true if it resulted from disease of the system of blood-vessels or of the nervous system, or from any condition which had become general, and of which cancer was a secondary result. Thus a general loss of power in the tissues of the body to maintain their integrity in the face of disturbing causes must be regarded as a constitutional condition, and we are obliged to assume the same even of such cases where a tissue is studded with primary germs of tumors. Multiply a local condition indefinitely, and we have finally a constitutional condition. Now, this faith in the local origin of tumors and cancers has given rise to many speculations in regard to the exact nature of the local influences which are able to produce such disastrous results. The most famous of these is the hypothesis of Cohnheim, who supposed that all neoplasms, of whatever kind, had their source in residual germs of embryonic origin. These germs were believed to consist of superfluous formative material which was not needed in the development of the various organs, and remained in a latent condition buried among the completed tissues, and retaining their embryonic power of evolution. They were then liable under any sufficient stimulus to become active and develop, at a time when they could serve no physiological purpose, into masses, whose relations with the rest of the organism must of necessity be abnormal and illegitimate. Such germs as dated from the earlier periods of embryonic life were credited with enormous powers of growth and multiplication and a peculiar aggressive force, against which the normal tissues were powerless. In this way was accounted for that peculiar power of malignant growths by virtue of which cancers and sarcomata were enabled to infect the body. How plausible such a theory would seem to the ardent believers in the doctrines of local origin is of course apparent. I was myself very enthusiastic in my reception of the hypothesis at the first reading, and the idea was especially welcomed because it seemed to place on a firm basis that doctrine on which surgeons based their most ardent hopes of success in their struggles against malignant diseases.

It must not be forgotten, however, that even Cohnheim was obliged to incorporate in this theory an hypothesis of constitutional influence in order to account for the long periods during which these germs lie latent, notwithstanding their subjection to the most varied kinds of irritation.

He imagined that every normal tissue had the power of resisting the encroachments upon its territory of any and every other tissue, and that only when the power of resistance had from any cause been lessened or lost did it become possible even for the most aggressive germ to develop and grow. In this admission he may be said to grant the whole question of a constitutional origin for tumors and cancers. Whether we are disposed or not to think well of this speculation, it is probable that our bodies, so to speak, swarm with germs which await only the proper stimulus to develop into tissue. Every regeneration of tissue after injury points to this conclusion. The immense growth of integument over large tumors, such as the large lipoma of the back, shows the vast capacity of normal tissue to develop under the proper stimulus. Whether the germs which then develop, or which develop into morbid tumors, are of embryonic origin, is, however, quite another question. In any case this may be regarded certain, that the mere presence of a potent germ is insufficient to account for its growth. The uterus, for example, is supposed by Cohnheim to contain vast masses of such germinal material which are vitalized by nature in pregnancy to enable the womb to grow to the necessary size and capacity, and which when cheated of their proper destiny are apt to develop into fibroid tumors. In fact, however, the vast majority of maiden ladies and childless married women are not afflicted with fibromata or fibro-myxomata, even though the uterus may have been stimulated by frequent or even habitual sexual intercourse. It is evident that there is in normal life some restraining power, some constitutional government which does not permit every rebellious cell to sprout and grow after its own fashion. While the origin of very many tumors from embryonic germs must be considered exceedingly doubtful, there is a class of growths which can be explained in no other way than by referring their beginning to anomalies of development. These are the dermoid cysts, the parotid enchondroma, the adenoma of the axilla, Grawitz's tumor of the kidneys, and some others. The peculiarity of their class is that they present examples of growths composed of adult tissues which are heterologous to the tissue in which they are located.

The explanation of such tumors by the assumption that they have sprung from aberrant or dislocated germs, which in some early period of fetal life by some hook or crook have got into strange neighborhoods, has of late years gained much credence among pathologists. Putting aside the dermoid cyst of the ovary and of the testes, whose origin is obscure, it seems highly probable that those which are formed along the edges of the branchial clefts, on the line of junction of the ventral lamina, are due to the infolding of the edges of the epiblast at its line of union, and the burial of some of its germs among the deeper parts. We may believe, too, that a cartilaginous tumor of the parotid may have had its origin from some germ accidentally detached from the ear. The adenoma of the axilla may in early life have formed part of that material set apart for the formation of the mammary

gland, and that those tumors of the kidney which, as Grawitz has demonstrated, exhibit a structure like that of the suprarenal capsule, may be reasonably supposed to have been portions of that organ which had become embedded in the kidney during its process of evolution. It is possible that those theories may be all wrong, and that the whole process of evolution may have got awry in such a way as to cause tissues which ought to develop from the epiblast to develop from the mesoblast, and *vice versa*. However that may be, it is highly probable that all tumors of this kind are due to some anomaly of embryonic life. It is a striking fact that since the attention of pathologists has been directed to this point the examples of heteroplasia have rapidly accumulated. It has, indeed, become the fashion for ambitious pathologists to hunt in morbid tumors for structure which would indicate this kind of origin. One important investigation has, however, been apparently neglected, and that is the careful examination of fetal organs with the view of determining to what extent a certain dislocation of germ is the rule during the process of evolution. It is, for instance, by no means impossible that nature may do her work habitually in a somewhat slovenly manner, and that the epiblastic germs may usually, if not always, become infolded and buried in the mesoblast during the process of uniting the various embryonic laminæ. The investigation of tissue and organs shortly after their differentiation might do much to clear up this question, a most vital one, as I regard it, in the pathology of these growths. Should we find that processes are habitual, which we have become accustomed to regard as exceptional, the whole subject would assume a different aspect. At present we infer that these tumors are due to the dislocation of germs, but if this kind of dislocation should prove to be the rule of evolution, we should then have to ask why, in a given case, the dislocated germinal matter, which in the natural course of things, as nature completed her work, ought to have been disintegrated and absorbed, has been able to persist, develop, and grow in defiance of physiological laws.

It is a serious question, too, whether every heterologous group of cells ought to be called a tumor. When particles of the epiblast, which, normally developed, would make a square inch of skin, become buried in the mesoblast and form there a square inch of similar tissue, is that a tumor in the same sense that a lipoma is a tumor? Extra fingers and toes growing from superfluous germs, having become attached, by a thread of connective-tissue, far from the normal location of fingers and toes, are they to be regarded as tumors? When a tooth grows down into the body of the lower jaw, or, as I once found one, in the upper part of the antrum, is it a tumor? In short, should mere dislocation of tissue be sufficient to constitute a neoplasm in the same sense that a lipoma or sarcoma is a neoplasm? There is one property that they have in common with true tumors. They persist in defiance of that general law of nature by virtue of which useless structures atrophy and disappear. That law is so decided in every other condition, whether physiological or pathological, that the exceptions seem to be confined to tumors alone, and to be their one pathological symptom. A tumor might be very correctly defined as a mass of useless tissue which develops, grows, and persists in defiance of physiological laws. The alveolar process disappears after the loss of the teeth, the breast and womb atrophy after the climacteric period, the unused bone becomes soft and thin, the muscles of a stump undergo fatty degeneration. Where, excepting among tumors, do we find an exception to this rule? In other respects these tumors of embryonic origin differ from many others, and notably from cancer and sarcoma. They exhibit in the first place that diversity of structure which we should expect from the development of a material which contains in itself the potentiality of all tissues. In dermoid cysts we find epidermis, hair, bone, teeth. The enchondromata of the parotid is usually a tumor of mixed tissues; the adenoma contains both the glandular structure and the connective-tissue in which it finds its support. The mole is a medley of sebaceous glands, hair, epidermis, and sweat-glands; and the several tumors which spring from embryonic vestiges are always remarkable for the variety of their contained tissue. Should we not expect the same phenomena in all tumors, if, as Cohnheim supposes, all tumors spring from such potential germs? This is, however, not the case. A cancer is composed of the simplest form of epithelial cells. It not only shows no variety of tissue-formation, but its epithelial cells are always of the same kind. If the mother tumor is composed of cylindrical epithelium, every secondary knot in the whole body will show the same formation.

A sarcoma, unless it springs from some embryonic residue, shows usually one form of young connective-tissue cells, and but one, and the secondary tumors repeat that form indefinitely. Now this is what we might expect from those growths springing from pre-existing adult cells, but not if they owed their existence to embryonic germs. The type of an adult tissue is fixed. Its cells may generate their successors and perpetuate their race, but they cannot change their form or character. The metaplasia of which Virchow speaks is confined, for the most part, in normal relations to immature structure, and in pathological matters presents a vexed and undecided question. It is certainly a rare phenomenon in normal adult life. As far as our present experience goes, we may safely assume that when a tumor presents in all of its parts, and in all of its generations, a fixed monotonous form of cellular elements, it owes its source to adult tissue. The term embryonic, as applied to the cells of certain tumors, has led, doubtless, to some confusion. It can be properly applied only to the form of the cells, not to its source. The young cells of adult tissue may be embryonic in form, although they do not date by any means from fetal life. I will say one word more in explanation of the term adult tissue. I understand by adult tissue one which has reached its maximum of development, no matter at what age that may occur. The epidermis of a child may be an adult tissue, while its bones may be made up of immature tissue. If, then, the question arise in regard to any given tumor, whether it was or was not of embryonic origin, I should not hesitate, as a test, to inquire into the evidence which is presented of development, as well as growth and multiplication of cells. Embryonic germs develop into vast varieties of forms while the progeny of adult cells repeat indefinitely the form of their progenitors.

Applying this test to Cohnheim's theory, we must deny that mode of origin. It is to be noticed further, before leaving this subject, that the immense power of growth and cell multiplication which some tumors exhibit, and which Cohnheim regards as an expression of embryonic energy, is more a feature of embryonic than of adult life. A fœtus grows, it is true, with vast rapidity, but it grows, nevertheless, in accordance with law, and its power of growth and evolution both diminish with age. In normal life this is the rule. As time goes on, development first, and then growth, comes to a standstill, and finally the organism in all its parts is engaged to the end in the struggle to maintain what it has acquired. The development of a tumor, on the contrary, is something contrary to all of our experience with normal tissue, and the terrific momentum which a cancer or round-celled sarcoma acquires in its progress, is something as foreign to embryonic as to adult life. Every surgeon knows by bitter experience how steadily the aggressive malignity of an infectious tumor increases with age. For these reasons I cannot but feel that the evident origin of many tumors from anomalies of development has been given a significance which the facts do not warrant. If, however, we respect Cohnheim's hypothesis, we have no tenable theory whatever by which we may explain the phenomena of cancer and tumors as a merely local disease.

Mr. Savory, who apparently respects all constitutional influences as factors in the production of these maladies, ascribes the malignancy of cancer and sarcoma to the low character of their component protoplasm. Recognizing that the so-called cancer cells are embryonic in form only, and lack all embryonic power of development, he seeks to account for their aggressive power of multiplication on the assumption that protoplasmic cells of low grade have inherent powers of growth and multiplication far in excess of tissues which are capable of higher development. In this power we are to seek for the reason of that hitherto inexplicable fact that the elements of malignant growth penetrate into all surrounding structures, growing at their expense and actually devouring their substance.

Unfortunately this is one of those explanations which does not explain ; for if we grant, what is by no means proven, the truth of this assumption, we are no nearer the true mystery, for we have yet to ask how it happened that normal structures become liable to give birth to such illegitimate and formidable progeny, and in the answer to that inquiry we find involved again the whole question of constitutional or local origin. There are, however, good reasons for believing that the solution of the problem is not to be found alone in any peculiarity of the protoplasm or protoplasmic cells of the tumor. Certain ulcers of quite innocent character exist only because the epidermis of the part is incapable of producing a sufficient amount of highly organized cells to make up for the loss by wear and tear. Such epidermis produces young broods of embryonic form which lack embryonic power, but they do not grow into cancers. They are simply disintegrated and destroyed. So, too, among those diseases which are esteemed cancerous we find differences in the grades of their component cells. The elements of a cancroid of the face are, as far as we know, fully as degraded as those of an epithelioma of the lip, and those of the latter as those of a scirrhus, but the degree of malignancy is by no means the same. If, putting aside the prejudices which have grown up during a generation, we ask what facts there are which are incompatible with any theory of purely local origin of cancers or tumors, we will find them to consist of two groups, the one of which includes such facts as relate especially to cancers and tumors ; to their characteristics as regards heredity, to the relations existing between benign and foreign growths, to the peculiarities of race and climate, to the endermic influences which foster or retard their growth, or to changes in, near, or distant from, the affected tissue which takes place before the advent of the tumor. The other group consists of those facts which serve to indicate, however obscure, that law which governs the development of all tissues and regulates the relations of any one part of the body to every other. Of the former group clinical evidences come first in order, both from their inherent value and from their precedence in point of time of other facts which are ascertained with more difficulty. The simultaneous appearance of several primary tumors indicates a constitutional tendency to tumors. Every surgeon has met with such cases of multiple primary cancers, multiple lipomas, multiple exostosis and the like. If we accept Virchow's explanation of these cases—that they represent only multiple local force, usually confined to but one kind of tissue—we shall, nevertheless, have a condition which, for all practical purposes, must be considered constitutional. If the connective-tissue swarms with young primary sarcomata, is it not just as essentially constitutional as if they swarmed in the blood ? If I do not dwell upon cases of this description it is because the plausible explanation has rendered it possible to reconcile the appearances of multiple primary tumors occurring in one tissue with the theory of local origin. It is otherwise when we find tumors of various kinds occurring in the most varied tissues of the body, and composed of cells of both epiblastic and mesoblastic origin.

THE TREATMENT OF MASTITIS BY REST AND PRESSURE.

By W. F. MILROY, M.D.,

LATE HOUSE-SURGEON TO MATERNITY HOSPITAL, NEW YORK CITY ; PROFESSOR OF HISTOLOGY AND PATHOLOGY IN THE OMAHA MEDICAL COLLEGE, OMAHA, NEB.

WHILE house-surgeon to Maternity Hospital, New York City, a year ago, during the service of Dr. Paul F. Mundé, and through his kindness, I had an opportunity of developing an idea which resulted in the adoption of this mode of treatment in all of our cases in which this calamity threatened.

I had never seen anything written upon the subject, and the idea was suggested to my mind by the use of a support for unusually pendulous breasts.

In the main my experience exactly coincides with that of Dr. Harris, as related in his exhaustive paper to which your editorial of May 30th refers. There are, however, several points of difference which appear to me to be of sufficient importance to warrant their presentation.

My method is as follows :

A piece of strong muslin is used, fourteen to sixteen inches in width, and of a length sufficient to reach around the thorax of the patient and overlap a few inches. The patient lies upon her back with the arms elevated so as to clasp the hands above the head, thus drawing the axillæ well upward. One end of the muslin is slipped through beneath the patient, and the two ends made to overlap exactly as in the application of an abdominal binder. A pad of cotton wadding is placed between the breasts to serve as counter-pressure. The breasts are then pressed upward and toward the sternum by an assistant, and the muslin is fastened by pins, which are placed along the middle line about three-fourths of an inch apart. As the pins are put in place, the bandage is drawn tense by about all the force one can comfortably exert through his arms.

When the bandage has been fastened, proceeding in this way from above downward, it will usually be found that its upper part is comparatively loose, and a few pins should be removed and reapplied. The bandage should be brought well up against the axillæ, and thus the upper part of the breast will all be included within it. When it is in place, a small wad of cotton should be tucked in beneath the folds of the axilla above the bandage. This will relieve all feeling of irritation from the bandage in that location. A small hole should then be cut with a scissors over the nipple of the sound side, and the child allowed to nurse this breast. The one principle to be borne in mind in the application of this bandage is to make sure that every part of the breast is included in it, and that the pressure is even throughout. With reasonable care this is easily accomplished. In case the trouble occurs long enough after confinement, so that the patient is out of bed, a strap of muslin may be passed over each shoulder and pinned to the upper edge of the bandage, before and behind. This will overcome any tendency toward slipping down. If the patient is in bed this is wholly unnecessary. The bandage having been once applied need not be removed until the unpleasant symptoms are entirely gone, but may be tightened above and below, as the diminishing size of the breast will permit. After all tenderness is gone, having removed the bandage, the breast appears greatly reduced in size, the integument is relaxed in small wrinkles and folds, and no sign of inflammation is present. There is, however, a uniform induration over the entire organ, it being in a condition somewhat analogous to that of hepatized lung-tissue due to pleuritic effusion. From this it recovers in a few hours if the child be reapplied to the breast, and in a little longer time if the breast be allowed to remain inactive. I would emphasize the necessity for all parts of the breasts being subjected to pressure, for if this be not done, signs of inflammation will very soon appear in the part not compressed.

It will be observed that the most essential point of

difference between this treatment and that of Dr. Harris consists in the employment of *firm* pressure, instead of the slight pressure which he recommends. This I consider a positive advantage. It was a source of great surprise to me to note how much pressure can be brought to bear, with comfort to the patient, in the way I have described. In cases in which the mastitis had progressed so far as to produce an area of bright redness and induration, and so sensitive that the most careful handling produced severe pain, strong pressure made after this fashion gave immediate relief. I have never been able to pin a bandage so tightly as to increase the pain, provided it was evenly applied.

Dr. Harris, in describing his treatment, speaks of an increasing distention of the breast, as a rule, for one, two, or three days after the roller is applied, and says that there is no retrogression, and often an increase in the degree of redness, induration, and tenderness for a day or two; though often improvement begins immediately after its application. In my cases I have, without exception, seen a progressive decrease, from the first application of the bandage, in the distention of the gland and in the redness, tenderness, and induration, in cases in which these were present.

According to my theory of the *modus operandi* of this pressure, in addition to the advantages of rest, another very important element of gain is introduced. In the early part of any inflammation there is a dilatation of the capillaries and small arteries, not only of the inflamed part, but also of all the tissues in its neighborhood. There is also an increase in the rapidity of the blood-current in its flow through these parts, and, as a result of these two factors, the local increase in blood-supply is very great. It is with this early stage of inflammation that we have to do in the prevention of abscess in the mammary gland. Again, the stomach, the intestine, the liver, or any other digestive organ, during the time of its physiological activity, is engorged with blood; and without this increased blood-supply its functional activity is crippled or destroyed. In the same manner, during lactation, the mammary glands normally receive an increased blood-supply, which is provided for during their development in the period of gestation.

Now, owing to the spongy and compressible nature of these glands and the unyielding underlying chest-wall, it is possible so to apply pressure, that, simply by mechanical force, the amount of blood gaining access to them is very much diminished. This being done, we have the danger of inflammation, in an equal ratio, reduced, and that by a twofold action: first, by the actual lessening of the degree of congestion of the part, and, secondly, by diminishing the excessive secretion of milk, which is undoubtedly a potent agent in the production of inflammation. It is true that inflammation itself checks the secretion of milk, but this occurs at a later stage than that at which the bandage will be applied. By the use of such pressure as I have indicated, advantage is taken of this powerful agent in accomplishing the end desired. That it does serve a useful purpose is shown by the fact that recovery begins promptly upon the application of the pressure, so that no further development of the inflammatory symptoms occurs, and also by the rapidity of the cure. Dr. Harris refers to the use of the many-tailed bandage in this affection, as recommended by Dr. L. A. Dugas. I have given the many-tailed bandage no extended trial, but it seems to me impossible to obtain the uniformity of pressure by its use which is essential.

The following objections, suggested by Dr. Harris to the use of the many-tailed bandage, he would evidently apply as well to the bandage that I have described, viz.: "In exerting compression it must flatten the gland and tend to press it out of form. It does not lift the breast—a measure which is always grateful to the patient and beneficial to the inflamed organ. It must exert a greater restraint upon respiration than though the breasts were first lifted and the shoulders included in the bandage."

To the first of these objections I would say, there is no doubt that pressure applied as I have suggested does "flatten the gland," and to a slight degree "press it out of form;" but this I regard of no consequence whatever, since in a very short time after removal of the bandage the gland returns to its normal shape. The breast is effectually lifted and retained in the elevated position, and, therefore, the second objection does not hold.

To the third I answer that I have once or twice heard patients complain of slight discomfort from constriction when the bandage was first applied, but before it had been an hour in place they experienced the discomfort no longer.

Mastitis is a disease so common that every general practitioner must be frequently called upon to treat it. Any mode of treatment, whether of mastitis or any other prevalent disease, in order to come into general use must be of such simplicity and ease of application that the average physician can adapt it successfully to his patient. Now, it must be apparent to any one who reads the description of the application of Dr. Harris' bandage, that its complexity will deter very many from attempting its use, and many more from succeeding in it. Let him who does not think so make trial of it once. Dr. Harris quotes Velpeau, in speaking of this use of the roller bandage, as follows: "The great drawback to its use is the difficulty of applying it in such a manner as to exert equable pressure and at the same time prevent displacement, which movements of the head, trunk, and arms are so apt to bring about."

When a man of Velpeau's genius meets with so much difficulty it is hardly possible that the use of "eighteen large safety-pins," as suggested by Dr. Harris, can obviate the whole difficulty. The extreme simplicity of the bandage, as I have described it, assures its successful application by any one who cares to make the attempt.

I would also call attention to the facility of examination of the breast while this bandage is still in place. Since but a single thickness of muslin covers it palpation shows the exact condition of the breast beneath, and once applied, as I have already stated, it need not be removed until it is no longer needed.

Still another point of advantage of the single piece of muslin over the roller is the absence of the cotton padding which accompanies the use of the latter. The heat of this pad gives more or less discomfort, and, probably, to some extent, delays resolution.

Another point of gain rests in the fact that the patient lies on her back during the application of the bandage I have described. This avoids the exertion and positive danger that attends her sitting up, if the case is one of recent confinement.

For the sake of brevity I will relate but a single one of the thirteen cases of which I have a history. This one I have selected because it was quite aggravated, and also because it showed the result of the old method of treatment, by emptying the breast, as compared with that by rest and pressure.

CASE.—Bridget S——, aged twenty-eight, American, primipara, fairly nourished, was confined June 17, 1884. At the time of confinement both nipples were considerably depressed. The child was put to the breast as usual.

June 21st.—Temperature, 99.6°; pulse, 90; respiration, 18. Both nipples slightly sore. Ordered to carefully dry the nipples and dust them with tannic acid when the child is not nursing.

June 22d.—Condition about the same.

June 23d.—P.M.: Temperature, 101.3°; pulse, 108; respiration, 26. Breasts very full and painful; nipples still sore; head aches; is inclined to worry. Ordered the breasts nursed out and tannin applied to the nipples when the child is not nursing and the breasts supported by a bandage.

June 24th.—9 A.M.: Temperature, 101°; pulse, 108; respiration, 32. Breasts very full, and there is a red, painful, and indurated spot, about two inches in diameter, in the upper part of the left breast, causing great distress. Both nipples are very sore; patient slept but little last night; is much exhausted; anorexia complete. Ordered the breasts thoroughly nursed out and supported. Tannin applied to the nipples during the intervals of nursing.

June 24th.—6 P.M.: Since last seen, two babies, one on each breast, were kept nursing almost constantly until 3 P.M. At this time the breasts still appeared nearly full of milk. The inflamed spot at the upper part of the left breast remained as described. The nipples became extremely sore and the pain from nursing unendurable. At 3 P.M. the nurse began "rubbing out" the breasts and has been thus employed for three hours. It seems impossible to empty the breasts, as they are still well filled. The induration is but slightly diminished. The general condition of the patient rather worse than this morning. Temperature, 101.3°; pulse, 100; respiration, 33. The nipples were thoroughly dusted with tannin and the bandage tightly applied as described, affording instant relief to the pain.

It should be remembered that the Maternity afforded an abundant supply of babies for carrying out the above plan. A rubber nipple-shield was used during nursing from the time the nipples began to be sore.

June 25th.—A.M.: Temperature, 99°; pulse, 80; respiration, 20. Patient rested well during the night and feels much better. The breasts feel comfortable except at the upper part of the left one. In this situation the bandage has become slightly relaxed. The milk has been draining away from both breasts constantly since the application of the bandage.

The bandage was tightened above and below and all pain instantly relieved.

June 25th.—P.M.: The breasts have been comfortable all day but constantly discharging milk. The bandage was drawn a little closer at the upper part.

June 26th.—A.M.: Temperature, 98.4°; pulse, 92; respiration, 18. The patient slept well and is very bright this morning. There is no pain or tenderness in the breasts, and the induration at the site of inflammation is not perceptible. The milk has ceased to drain away from the breasts. The bandage not disturbed.

June 27th.—A.M.: Temperature, 98.5°; pulse, 90; respiration, 18. The breasts are perfectly comfortable. Patient rested well, but is weak and appetite poor. The breast-bandage again tightened.

On the evening of this day (June 27th) the bandage was removed and the breasts found in the condition already described as usual after removal of the bandage. They still contained some milk. The nipples, though still quite sore, were very greatly improved. The breasts were nursed out and the tannin dressing continued to the nipples as before.

It was our custom to transfer all patients, whose convalescence was normal, from the pavilion in which they were retained after confinement to the "convalescent ward," in the main hospital building, on the eighth or ninth day, the transfer being made upon a stretcher.

This patient was not transferred until June 27th, the eleventh day. It almost invariably happened in cases in which there was a hypersecretion of milk that this ceased as soon as this transfer was made. In the present instance, after the transfer was made, the patient had only enough milk for her own child and there was no further trouble with the breasts.

In this case all attempts to empty the breasts by the natural method were fruitless and the condition of the nipples had become simply frightful.

The employment of the "rubbing process" was undertaken with the same result, and in the midst of our very efforts the inflammatory process was developing. The patient was rapidly becoming exhausted, and under old methods of treatment one or more abscesses seemed inevitable. Could any combination of circumstances more satisfactorily demonstrate the efficiency of the treatment I have described?

Your editorial refers to the desirability of further light upon the method of treating sore nipples by bandaging the breast. So far as my experience goes severely excoriated nipples will seldom be met with unaccompanied by trouble with the breasts as well. When allowed to rest, the nipples recover with remarkable rapidity, and it would seem advisable, at least in aggravated cases, to adopt this plan.

2208 FARNUM STREET.

Clinical Department

A CASE OF MORPHIA POISONING IN A CHILD AGED FIFTY HOURS.

DR. WILLIAM JUDKINS, of Cincinnati, O., reports a case of morphia poisoning in an infant aged *fifty hours*, where by mistake a quarter of a grain of morphia in solution was given. At the time the doctor was summoned, two hours after the first dose was taken (an eighth of a grain in a teaspoonful of water, for supposed colic; the first dose not having the desired effect it was repeated an hour afterward), the child was cyanotic, breathing only three times to the minute, and that very feeble; pulse barely perceptible. Immersions in hot water were at once commenced, and whiskey hypodermatically, in the gastrocnemius. Strong black coffee was also administered per orem and anus. After two hours' constant work, respirations increased in frequency and the heart's action became stronger. Recovery was final, and now, ten weeks after the accident, the child is as well and bright as could be wished. The catheter had to be used several times the first twenty-four hours, and three abscesses were opened that were produced by the frequent introduction of the hypodermic needle. The doctor states he has been unable to find a similar case on record.

Progress of Medical Science.

INHALATIONS OF OXYGEN IN PUERPERAL ECLAMPSIA.—At a recent meeting of the medical section of the Kharkov Society of Experimental Sciences, Professor V. G. Lashkevitch, in the course of a communication on the therapeutic value of oxygen in neuro-pathology, pointed out that oxygen possesses a considerable power of lowering an increased reflex action, and also made the suggestion that oxygen-inhalations may prove of service in cases of puerperal eclampsia. Acting on the suggestion of Professor Lashkevitch, Dr. V. G. Favr, of Kharkov (*Vratch*, No. 13, 1885), resorted to oxygen in two cases, and obtained brilliant results. The first of the cases was that of a seamstress, primipara, aged nineteen, who was brought to the hospital in an unconscious state, with cyanosis, stertorous breathing, and frequent eclamptic seizures, each of the latter being preceded by a uterine contraction. Warm baths, wet packings, and enemata with chloral-hydrate brought no relief; chloroform-inhalations only slightly controlled the intensity of the convulsive paroxysms. In view of the failure of all these means, oxygen was tried. In five minutes from the beginning of the inhalations, the patient asked for water, and then fell into a quiet sleep of two hours' duration, the pulse descending from 120 to 90 per minute; uterine contractions ceased to be a starting-point for convulsive fits. The latter reappeared each time when the inhalations had been stopped, and again gave place to sleep and quiet on resuming the administration of oxygen. The delivery was accomplished with the help of Barnes' dilators, and of puncture of the membranes.

The patient left the hospital on the nineteenth day after the labor, her general health and the state of the kidneys being greatly improved under an appropriate treatment. A second patient, primipara, aged eighteen, was attacked with eclampsia about an hour and a half after the labor. Two severe paroxysms (each of twelve minutes' duration, separated by a free interval of twenty minutes, during which the patient remained unconscious) had occurred before oxygen inhalations could be resorted to. Consciousness returned immediately. Four more paroxysms occurred, but they were considerably milder, and separated by the intervals of absolute comfort; indeed, the patient took her tea and dinner between the eclamptic fits. She made a rapid recovery. Encouraged by his success, Dr. Favr enthusiastically invites all professional brethern to give a trial to so simple a weapon against so formidable a foe, and even goes so far as to ardently hope that in a near future oxygen-gasometers will be found in all lying-in hospitals, side by side with forceps, cranioclast, cephalotribe, and other necessary instruments.—*London Medical Record*, June 15, 1885.

The So-called Fatty Diarrhœa of Demme and Biedert.—Dr. Tschernoff has made a large number of analyses of the stools of healthy and diseased infants. The fat in seven healthy children under six months old amounted to from 25 to 30 per cent. of the dried fæces. The average quantity in four dyspeptic children was 48 per cent. Two infants with erysipelas showed respectively 44 and 52 per cent., and the amount remained high long after their recovery. Two cases of catarrhal pneumonia gave 51 per cent. each, and another case 60 per cent. A child with bronchitis and nearly normal temperature showed 39 per cent.; another with chronic diarrhœa 42 per cent. A child nine months old showed during an attack of scarlatina 57 per cent., and after recovery only 32 per cent. The next case was remarkable, for the stools, which were frequent, offensive, and whitish, contained, when dried, no less than 75 per cent. of fatty matter; the child, aged two months, was icteric, with greatly enlarged liver and spleen. A wasted child six months old, nursed by its mother, had diarrhœa, with slimy, blood-stained, offensive stools, which showed 50 per cent. of fat. After treatment, including the substitution of a wet-nurse, the child recovered, and regained all its flesh, but the dried stools still showed 40 per cent. of fat. This case exemplifies the difficulty with which children regain their power of assimilating fat. In the experience of the author, every disturbance of the digestive tract is accompanied by increased fat in the stools, and this increase is greater still if the temperature is raised. Even adults, when feverish, show an increase of 14 per cent. The quantity of fat in the food does not seem to affect the proportion in the stools.—*London Medical Record*, June 15, 1885.

Resorcin in Malignant New Growths.—In the *Russkaia Meditzina*, No. 6, 1885, Dr. G. J. Gatchkovsky details four cases of cancer-like new growths, in which he, following the instance of Dr. Mannino, applied locally resorcin, either in substance or in the shape of a 50 per cent. vaseline ointment. In two cases of what seemed to be epithelioma of the lower lip, complete cicatrization followed after eight and five weeks' treatment; in one of them there was no return up to the date of the article (thirteen months have elapsed); but in the second case, by the end of two months the cicatricial tissue became exulcerated, and lancinating pain reappeared; the ulcer again healed under resorcin treatment of three weeks' duration. A third patient, a woman aged fifty-six, presented a malignant tumor of the anal margin, as large as a hazel-nut, and diffuse cartilaginous infiltration of the lower part of the rectum. The tumor entirely disappeared after fifteen days' powdering, twice a day, with resorcin; subsequently daily rectal suppositories with twenty grains of resorcin were administered, but unfortunately the patient soon left the town, and thus was lost out of sight. A fourth patient, a woman aged forty-five, was admitted to the hospital about one month before her death, with advanced cancerous destruction of the whole right half of the tongue, and with induration of the submaxillary lymphatic glands. Powdering (twice daily) with resorcin rapidly removed the offensive odor and hæmorrhagic tendency, and also greatly improved the general state of the ulcer. Dr. Gatchkovsky found resorcin in powder of great use, also in cases of acuminated condylomata and fungus umbilici.—*London Medical Record*, June 15, 1885.

The Influence of Cocaine, Atropine, and Caffeine on the Heart and Blood-vessels.—From an experimental paper on the influence of cocaine, atropine, and caffeine on the heart and blood-vessels, by Dr. H. G. Beyer, U. S. N., *The American Journal of the Medical Sciences*, July, 1885, concludes: 1. That *cocaine* is exceedingly prompt and uniform in its effects upon the heart. 2. In small doses it is a powerful stimulant to the heart's action. 3. In medium doses it has an inhibitory influence over the ventricular contractions. 4. In large doses it produces diastolic arrest, from which, however, the heart may be recovered under suitable conditions. 5. In small or large doses it produces contraction of the blood-vessels, independent of the central nervous system. 6. A rise in the blood-pressure consequent upon the administration of cocaine is due to a direct action of the drug on the heart and blood-vessels, stimulating the former and constricting the latter; a fall in blood-pressure coming on after the rise must be accounted for by the action of cocaine on the heart alone, since its constricting influence on the blood-vessels outlasts the stimulating influence it exerts over the ventricle of the heart. That *atropine* in certain doses increases the rate of beat of the heart, and also the amount of work done; that it exercises an inhibitory influence over the contractions of the ventricle; that it first causes a contraction and afterward a dilatation of the blood-vessels; that cocaine acts on atropized vessels in the same way that it does on normal ones, *e. g.*, it causes their contraction. That *caffeine* in small as well as large doses produces dilatation of the blood-vessels in the terrapin; any rise in arterial pressure due to caffeine is, consequently, to be explained only by the stimulating effect caffeine exerts on the heart itself.

The Etiology of Erysipelas.—The now fairly-well-determined fact that erysipelas is a disease due to the invasion of micrococci has not hitherto led to a sufficient explanation of the varieties of the disease, and particularly of the points of difference and of resemblance between traumatic and idiopathic (so-called) erysipelas. In an interesting study of the subject in Virchow's *Archiv*, Dr. Rheimer, after reviewing the evidence as yet adduced concerning the nature of erysipelas, details the results of his examination of two cases of typhoid fever in which this complication occurred. The cases arose in a very severe epidemic which took place in Zurich in the spring of 1884, and he contrasts the microscopical characters of the affected skin, and other tissues obtained from them, with those observed in traumatic erysipelas. In the latter he describes not only masses of minute cocci in the lymphatic spaces and vessels, but also very definite chains of larger cocci and diplococci, apparently the same as those originally described by Recklinghausen, and since by Lukomsky, Koch, Ziegler, and many others. In typhoid erysipelas these last-named micro-organisms were conspicuous by their absence; for although the minuter forms were present in much the same situations and character as in traumatic cases, there were, instead of large micrococci, a number of mostly straight rod-shaped organisms scattered throughout the tissue. These organisms stained badly with reagents, and were apparently identical with the bacilli which Klebs, Eberth, and Gaffky have found more or less constantly in typhoid fever. Although the fact of the existence of a "bacillus typhosus" is still *sub*

judice, and has, indeed, been contested by many, it receives a certain amount of confirmation from this discovery. The latter has, however, a bearing upon the etiology of erysipelas, as indicating that the cutaneous lesion—*i.e.*, the dermatitis—may, indeed, be excited by more than one kind of poison, or, perhaps, to speak more correctly, by more than one kind of micro-parasite. It may be that there is a specific erysipelas organism for the traumatic affection; but it is possible that the spontaneous cases, and especially those which arise as complications of other infective diseases, own a different etiology. The question is a suggestive one, and offers a fertile field for further research.—*Lancet*, June 13, 1885.

Œdema of the Glottis in Tabes Dorsalis.—Any phenomenon may be met with in the course of tabes dorsalis; at least, this statement would seem to be a warrantable conclusion from known facts. We must not lose sight of the circumstance that accidental phenomena also exist and may occur in tabes dorsalis, as in any other disease, without any special significance. M. Huchard read at a recent meeting of the Société Médicale des Hôpitaux a paper on a case of œdema of the glottis following the administration of iodide of potassium in a patient the subject of tabes dorsalis. There was no history of syphilis or alcoholism, and no evidence of Bright's disease. The man was treated on account of the locomotor ataxy with four grammes of iodide of potassium per day. The treatment had to be suspended owing to the induction of iodism. After some days the medicament was given in smaller doses. This renewed treatment was followed by grave attacks of dyspnœa, which threatened suffocation. M. Gougenheim detected œdema of the arytenoid region by laryngoscopic examination. During one of the attacks the "interne" was obliged to perform tracheotomy. The patient ultimately did well. M. Huchard thought that the grave result was largely due to the influence of the iodide of potassium, while admitting that a sensory disturbance in tabes dorsalis may have played a part in the occurrence of the phenomenon. Chemical examination of the iodide of potassium showed that it was impure and contained a certain amount of iodates.—*Lancet*.

The Hygienic and Climatic Treatment of Pulmonary Phthisis.—This year's Croonian Lectures were delivered before the Royal College of Physicians in London by Dr. Hermann Weber. By pulmonary phthisis the author means a chronic disease of the lungs, with consolidation beginning almost always at the apex, having a tendency to caseation, softening, and the formation of cavities, or of fibrous changes; all the changes may occur in the same individual at the same time in different parts of the lungs, or may follow one another at different periods of the disease. These changes are mostly found associated with the tubercle-bacillus, discovered by Koch, and are intimately connected with a state of malnutrition of the whole organism, especially the cells and tissue of the lungs. There is no doubt that the bacillus is intimately connected with phthisis, but the exact relations appear to require further elucidation, as to why it thrives in some persons and not in others; or why it thrives in a person at one time and not at another. It is known that the range of temperature within which the bacillus of tubercle can grow is much more restricted than in the case of some of the other bacilli. Its growth entirely ceases below about 82° F., and above 107° F.; it thrives best at about 98° F. to 100° F. A further point against the spread of the tubercle-bacillus out of the animal body is that it does not form spores in the air. When there is any catarrh of the mucous membrane of the bronchi, and especially of the smaller divisions, and when the expiration is imperfectly performed, the bacillus finds a favorable opportunity for its development. The lecturer then shows that many cases of phthisis are certainly curable; and in the *post-mortem* room many instances are familiar to every one of old phthisical cavities having healed. With reference to treatment, it is impossible to restrict ourselves to that of the developed disease, and to pass over the preventive treatment. In many cases this is the only chance, for, when the disease is once established, in some constitutions it runs a rapid course. The poor have far less hope of recovery than the rich; and, contrary to what is the case in many diseases, existing hospitals cannot put the poor on a par with the rich in the question of the treatment of phthisis. That phthisis is capable of being transmitted from patient to patient is an accepted fact, in the author's mind, and numerous precautions are laid down with reference to the manner in which persons suffering from the disease should behave when living among those either with or without hereditary tendencies. The second lecture commences with the curative treatment of phthisis. This subject is divided under five headings: 1. Diet; 2. Air and ventilation; 3. Exercise; 4. Management of skin, clothing, etc.; 5. Climate. Food should be taken in small quantities and often, and the appetite should be humored as much as possible; milk is the most important article. Fresh air, good ventilation, and healthy exercise without fatigue, are essential. With regard to climate, the most essential feature is the purity of the air from floating matter. A soothing climate is not so good as a tonic one; it should allow the patient to remain in the open air, and at the same time enable him to take exercise and to gain an appetite. The author speaks very strongly on the use of alcohol by phthisical patients, and is convinced that in health alcohol is rarely necessary, but that in phthisis, especially in the febrile stage, it is of the greatest use, as long as the kidneys are sound. The third lecture deals with the effects of climate, and commences with remarks on the beneficial results produced by the dry cold of the Alps in winter on phthisical patients. Altitude climates are recommended in hereditary and acquired tendency to phthisis, but in advanced or complicated cases no benefit is derived from them. After mentioning several health-resorts, the author concludes by remarking that the climate of several places in Great Britain is good for the prevention of the disease, but not for developed cases. The health-resorts on the southern coast lack the necessary arrangements required to render them suitable for consumptives; and Dr. Weber urges the medical profession to use their influence in securing the erection of well-arranged houses with suitable balconies, verandas, covered walks, seats, etc., and with shelters from cold winds, so that those who cannot afford a journey abroad may reap the full benefit derivable from home climate.—*London Medical Record*, June 15, 1885.

Differentiation between Tubercular and Fibroid Phthisis.—Sir Andrew Clark (*British Medical Journal*), speaking of the differentiation between tubercular phthisis and fibroid phthisis, says: "Tubercular phthisis is primarily of constitutional origin, and appears for the most part in the young. It is bilateral. Its course is accompanied by elevation of temperature and rapidity of circulation, by progressive loss of flesh, strength, and color; sometimes by laryngeal ulceration, and sometimes by sensations of painful exhaustion and *malaise*. It is usually rapid in its progress; the majority die within three years, and the few who, in consequence of fibroid complications, live for a longer time, enlarge the average duration of the disease to four or five years. On the other hand, fibroid phthisis is usually of local origin, and appears for the most part in the middle-aged. It is, in the main, unilateral. It is unaccompanied by elevation of temperature or hurry of circulation; flesh, color, and strength may remain but slightly affected for years. It is not incompatible with great bodily and mental energy. The urine always contains a little albumen. The progress of the malady is slow. Œdema is never absent throughout, and death, which seldom occurs within five years, is often delayed for thirty."

THE MEDICAL RECORD:

INFANT DIARRHŒA AND THERMIC FEVER.

THE opinion seems to be gaining ground among certain observers that there is some analogy or connection between ordinary heat-stroke and the summer diarrhœa of infancy. It is, of course, the universal experience of physicians practising in large cities that the frequency and mortality of infantile diarrhœa is in direct proportion to the extent and duration of the high temperature. Exactly how the heat acts does not seem so plain. Inasmuch as removal from the city to the country is so frequently followed by improvement and recovery, the bad effects of the heat have been supposed to be chiefly due to fermentative changes produced in food, and to increasing atmospheric impurity. The heat of the city, however, is very different from the heat of the country, disregarding all other factors, even though the thermometer may register the same in both places. The bricks and paving-stones of the city, in the unshaded glare of the sun, reflect and radiate an oppressive, stifling heat that is shut in by high walls; in the country, however, not only is there a free expanse for any breeze, but the trees and foliage combine to lessen the deadly effects of a prolonged high temperature.

There is reason to believe that several different conditions may be produced by continuous heat. Dr. Guiteras, in the March number of the *Therapeutic Gazette*, describes a thermic fever he has observed at Key West, that is apt to be compounded with typhoid and continuous malarial fever. This form of fever prevails only during the summer, disappearing at once with the advent of cooler weather. Poorly nourished, over-worked persons, living in close houses, are especially liable to be attacked. The writer notes the peculiar predisposition to fever affecting the inhabitants of the tropics from prolonged heat. While the nervous mechanism that inhibits heat production may not be exactly understood, it is certainly overtasked during the long tropical summers, and as a result fever is a very common symptom. Particularly among children is an elevated temperature present with the slightest indisposition. It is more a prolonged than necessarily excessive heat that appears to produce the thermic fever. The condition of infants living in the badly ventilated tenement-houses of a large city during the long summer months, seems not unlike that of those persons living in the tropics who are most apt to be affected by thermic fever.

It is not difficult to understand how digestive symptoms would assume a prominent place in infants suffering from such fever. Not only is the food upon which they are obliged to live subject to speedy fermentative changes, and impossible to procure very fresh, but heat depresses the nervous mechanism of digestion. The supposition that a sort of thermic fever acts as a main factor in causing indigestion and diarrhœa, instead of the diarrhœa or entero-colitis primarily producing the fever, has some points to commend it. We know that infantile diarrhœas begin to increase in frequency and fatality abruptly with the inception of hot weather, and as quickly stop at its close. Again, of the two hot months of summer in this city, the mean temperature of July is somewhat higher than that of August, and the death-rate from diarrhœal diseases of young children is very much larger in the former month than in the latter, although all other conditions are largely the same. When the weather for a time becomes cooler, the death-rate sensibly diminishes. If the trouble is primarily a thermic fever, the temperature should be elevated before the diarrhœal symptoms manifest themselves. This it is difficult to ascertain accurately, as most cases are brought to the physician for the relief of the diarrhœa. Many drooping, weak babies, without looseness of the bowels, would probably be found to have a fever during a prolonged hot spell if the thermometer were employed.

Instead of falling back on teething or malaria to explain fever in the absence of local symptoms, the direct effect of the heated atmosphere of summer will often afford a more natural explanation. The view that much of the summer complaint is really a form of thermic fever derives its principal interest from emphasizing a point of treatment, namely, the free employment of cooling applications. Dr. Comegys believes such cases should be treated more by the external use of cold water than by giving drugs. As the intestinal irritation is but a secondary condition, it does not require the stress of treatment that should be reserved for the primary factor, the fever. The avidity with which babies having summer complaint will drink water, and the evident relief they experience from cool sponging, are easily explained by the high fever and dry mouth accompanying this condition. Any new idea involving a radical change of treatment should be received very cautiously; but in reference to the summer diarrhœa of infancy, the more common employment of cool sponging will undoubtedly be beneficial.

A NEW FIELD FOR YOUNG DOCTORS.

THE old advice, "Go West," seems to be losing its force as applied to physicians. Western cities are, relatively speaking, crowded with medical men, and if the estimate be true that twenty-five per cent. of those who die under forty die from intemperance, the moral and social status of those who are surviving and practising is not very cheering.

To those who are intending to become doctors we would say at once, in a general way, "'Don't;' unless you see your way to a practice tolerably clearly before you." To those who have cast the die and got their diplomas we suggest the coast of Mexico, the Argentine Republic, and the Congo Free State. We have seen evidence that there are openings in all these places, but we would par-

ticularly call attention just now to the Congo. We have the authority of *The Lancet* for stating that there are openings for medical missionaries there.

Says our contemporary: "They would have the care of the persons employed at the stations and of the dispensary or hospital. There is ample scope for practice, including a large amount of surgery, among the natives, and unlimited opportunities for scientific exploration—botanical, geological, etc. Of course, only gentlemen in hearty sympathy with the missionaries would care for the appointment; but there are probably many young men who would be glad to devote a few years to such a field of practice, and it is impossible to predict what opportunities may open before any who might afterward desire to remain in the new Free Congo State."

Instead of dying of intemperance in the West, let our young doctors become medical missionaries in the East and help to build up a new State, if they can keep off the fever.

INTERMITTENT ALBUMINURIA.

It is only within a comparatively recent period that a condition has been recognized in which there is found albumen in the urine, the presence of which cannot be accounted for by any renal lesion or departure from apparent health. This has, rather inappropriately, been called physiological or normal albuminuria. The etiology of the affection, and the pathological conditions under which it occurs, are as yet unknown, though it would seem to be dependent upon some vaso-motor disturbance. In *La France Médicale* of June 25, 1885, Dr. Merklen reports a case of this sort, which would appear to furnish a slight clue to the nature of the malady. The patient was a youth, sixteen years of age, of ordinarily fair health, but with a family history of rheumatism. He himself was of somewhat lymphatic temperament, with pale face, skin prone to eruptions of acne, and some cyanosis and habitual coldness of the extremities. On two occasions, after a horseback ride, he was seized with a sudden but evanescent dimness of vision. An examination of the urine showed a considerable quantity of albumen. But there being no other signs of nephritis, the urine was examined daily for a week, and it was found that the water passed between noon and midnight was albuminous, while that passed from midnight to noon was free from the slightest trace of albumen. There were no casts at any time. An ophthalmoscopic examination, made by M. Giraud-Tenlon, revealed a slight turgescence of the retinal veins, a sign which the examiner interpreted as indicating vaso-motor atony. There was slight hypermetropia. The temporary visual defect was thought to be due to a sudden suspension of accommodation, occasioned by congestion or a central nervous trouble. Some months later the patient suffered from an acute pulmonary trouble accompanied by a high fever, and during the three weeks that the fever continued, the patient being confined to his bed, the albumen was absent from the urine, but returned again as soon as the patient recovered and began to walk about his room. Its appearance was intermittent as before. In view of these facts, the author was led to surmise that the albuminuria was due to vaso-motor disturbances which were not sufficiently marked to give rise to external manifestations during the period of rest and artificial warmth in bed, but which led to renal congestion, or blood stasis, when the patient was exercising or exposed to cold.

There is another form of intermittent albuminuria which has been noted by Dr. Eichhorst in adolescents, and which, although differing in its symptoms, as well as in its periodicity, from the variety just considered, may nevertheless be mentioned in this connection.

Dr. Eichhorst writes in the *Correspondenzblatt für Schweizer Aerzte*, No. 12, 1885, that he has observed, in individuals at the age of puberty, a peculiar indefinite train of morbid symptoms which did not seem referable to any organic lesion. A chance examination of the urine in one instance revealed the presence of albumen, and being thereby led to examine this fluid methodically, the author found that it was very frequently albuminous. The urine was of a light-yellow color, clear, and only once was a single hyaline cast discovered. The albuminuria was periodical, appearing at intervals of weeks or months, each attack lasting from a day to a week, but seldom longer. The general symptoms were divisible into three groups: 1. Lassitude, debility, weak memory, and mental distraction; 2. capriciousness, irritability, and mental excitement; 3. more rarely there were headache, vomiting, muscular twitchings, and even slight epileptiform seizures. The prognosis was in general favorable, though in some cases the albuminuria recurred at intervals during two years. Internal medication was without effect, and the best results were obtained by a life in the country and by nourishing food.

HOW TO CARRY, UNAIDED, AN INSENSIBLE MAN.

This question is asked by a correspondent in one of our English contemporaries. It is easy to see of what practical use the solution of such a problem would be before actually confronted with it. In battle, at a fire, in many places of danger, an individual becomes insensible, and must be immediately taken from the spot.

The London Fire Brigade teach their firemen how to do this. In a reply to the correspondent, the following description is given:

"A small platform, some forty or fifty feet high, has been erected on the roof of one of the buildings in the drill-yard. One-half of the men who are drilling go up to this platform and prostrate themselves in all kinds of peculiar attitudes, some on their backs, some on their sides, and some curled up. The other half have to go up and fetch them down single-handed. The rescuing fireman first straightens out the seemingly lifeless body of his comrade, and rolls it over onto the face. Then taking hold under each armpit, he raises the body onto his right knee, so that he can put the arm of the insensible man round his own neck. Taking a firm hold, he suddenly straightens himself up, and walks away with his burden in an upright position, and the whole weight of the other's body supported and hooked, as it were, by the arm. He has then to carry his comrade through the window as best he can, and shoot him down the escape."

Several other methods are described for the benefit of the inquiring correspondent. One is to carry the patient "pickapack." Another is to get him in a sitting posture, and for the rescuer to sit back to back with

him, and hook his arms into the patient's arms, and gradually raise himself and his load to the upright position. Still another method is described, that of taking the patient astride the shoulders, the legs having been first strapped together below the knees.

News of the Week.

A DECREE, gazetted Paris, July 8th, requires any person receiving a traveller from Spain to notify the municipality of the fact. Posts of observation are also to be created near Toulouse, Foix, and Perpignan.

FATAL TRICHINOSIS IN BALTIMORE.—Three deaths have occurred in one family from trichinosis following the eating of uncooked ham. They are said to be the first cases of the kind that have been observed in that city.

HENLE'S SUCCESSOR AT GÖTTINGEN has been found in the person of Professor Merkel, of Königsberg.

A PRIZE OF EIGHT HUNDRED DOLLARS has been offered by the Empress Augusta, of Germany, for the best portable hospital or sick-room tent for use in war and during epidemics, and will be awarded in connection with the Antwerp exhibition.

ANTHRAX IN LOUISIANA.—Charbon, or anthrax, prevails to a serious extent in Louisiana. Why not give Pasteur's protective inoculation a trial on American soil?

MEDICAL PROGRESS IN JAPAN.—A new building in Tokio, recently purchased by the Sei-i-Kwai (Society for the Advancement of Medical Science in Japan), for the purposes of a medical library and museum, was opened on March 18th, by the President of the Society, Dr. K. Takaki.

THE MEETING OF THE INTERNATIONAL CONGRESS OF HYDROLOGY AND CLIMATOLOGY, which was to be held at Biarritz on October 1st, has been postponed until the same date in 1886, in consequence of the general elections in France having been fixed for the sixteen days preceding October 14th of this year. It is not intended to make any other change in the programme.

VAN ERMENGEM ON FERRÁN.—Like Brouardel, of Paris, Dr. van Ermengem, of Brussels, is displeased with the results of his inquiry into Ferrán's mode of inoculation for cholera. Van Ermengem questioned and examined about three hundred persons who were inoculated and reinoculated. Not one of the individuals observed showed symptoms in the least suggestive of algidity. Six specimens of blood, taken twelve hours after inoculation, from the top of the first finger, were normal, and contained neither micrococci nor bacteria. In plate-cultivations in nutritive gelatine there was no development of micro-organisms. He did not observe that the slightest precautions were taken to prevent the access of particles from the air to the fluid used for inoculation. The fluid was collected in an unsterilized cup, protected against particles from the air only by an ordinary piece of paper. Even the syringes were only sterilized, as it was called, by having a little boiling water drawn through them. Dr. Ferrán neglects all the precautions that are observed in the laboratory in inoculations *in corpore vili*. The most difficult part of van Ermengem's task of investigation was as follows: He was obliged first to convince himself of the presence of comma bacilli in Ferrán's fluid-cultivations. The bacilli were rather scanty, and there were none of the forms of development that Ferrán pretends to have discovered. He saw that the cultivation-liquid of Ferrán was not very favorable to the development of the cholera-microbes, and that they speedily perished in it. Dr. Ferrán afterward took great trouble to let him see those foreign forms of the development-cycle in older cultivations which he has discovered. He showed van Ermengem, in *bouillon* that was fourteen days old and much changed in appearance, voluminous bodies of mulberry-leaf shape—five, even ten times the size of a blood-corpuscle—which he supposed to originate directly from endogenous spores of the comma bacillus! . . . Other rounded-off, but less voluminous corpuscles, which were found in the same liquid, corresponded, according to Ferrán's view, with free spores that had not developed so much. It is superfluous to say that these things are to be ascribed to impurities of quite a different origin. Van Ermengem was very much surprised to see that Dr. Ferrán is far from utilizing the perfected methods of bacterioscopy for the very delicate morphological investigations with which he is occupied; and everybody will be astonished, as he was, to hear that Ferrán has no object-glass with homogeneous immersion and Abbé's condenser, and that he omits to color the bacteria that he studies. His methods of cultivation, as far as van Ermengem is acquainted with them, are also not above criticism. He placed a series of written questions before Dr. Ferrán, the solution of which seemed to him to be indispensable before proceeding experimentally with the procedure adopted by Ferrán in producing his liquid. To his great regret, Dr. Ferrán declined to answer these questions. He sent word that the moment did not seem to him to have arrived for publishing what he calls his "secret."

LUMBAR NEPHRECTOMY.—Mr. Clement Lucas recently removed, in Guy's Hospital, a distended floating kidney, filled with large calculi, which could be felt through the abdominal parietes. The operation was performed without difficulty through the loin, leaving the peritoneum uninjured. The patient is progressing uninterruptedly toward recovery, her temperature continuing normal, as before the operation.

NEW CLINICAL INSTITUTE AT ST. PETERSBURG.—The Clinical Institute of Princess Helena Pawlowna, which has just been opened at St. Petersburg, is intended by the foundress to serve for instruction of a practical character to students of the University and of the Military Medical Academy in their last year, and to enable qualified men to work out specialties. Dr. E. Eichwaldt has been appointed Director, with charge of the Therapeutical Department. Dr. N. Monastyrski is to have charge of the Surgical Department, and Dr. A. J. Afanasieff has the Professorship of Pathological Anatomy. The Physiologico Chemical Laboratory is placed under Dr. Pöhl.

A SOCIETY OF GERMAN DENTISTS has been organized in Berlin. Its main object is the suppression of quackery in all that relates to dentistry.

Will the International Medical Congress Meet in America?—Should the arrangements for the meeting be continued under the existing strained circumstances nothing but disaster can ensue. It becomes an immediate question whether steps should not be taken for selecting another place than America as the scene of the next International Congress.—*The Medical Press and Circular*, July 22, 1885.

The most recent advices from the United States have brought the startling intelligence that there exists in the American medical profession a very serious discord concerning the next International Medical Congress. We do not propose to discuss the etiology of this rupture, for it is quite enough to be called upon to face the fact that it exists. The fact is very grave. Its existence jeopardizes, if it have not already destroyed, the probable success of the forthcoming Congress. Certainly our brethren in the States cannot expect those who have already promised to attend, and those who may expect to visit America at that time, to work with enthusiasm in the preparation of any scientific contribution while those whom they propose to visit are divided, and while wholesale secessions of the official executive and of well-known persons nominated to high offices are announced. Nor do we consider it to be either our duty or privilege to suggest a remedy for this exceedingly unpleasant dilemma. It seems to be conclusive that the profession in America at this moment is hopelessly divided on the subject. The outlook, as the matter now stands, is not at all encouraging. One committee has reorganized the work of another up to the point near that of destruction. Moreover, the work of the present committee must be submitted to the American Medical Association in May, 1886; and no one can say to what extent it may also be either overturned or modified in such a way as to seriously impede the labor necessary to be performed before the meeting of the Congress in 1887. Altogether, the position is lamentable, and there is much fear that the acceptance of the invitations to meet in the States may be withdrawn, and the next meeting of the International Medical Congress be held in Berlin or some other great medical centre, pending the settlement of the serious dissensions among our brethren of the United States.—*The British Medical Journal*, July 25, 1885.

Despite the very cheering assurances of the *Journal of the American Medical Association*, that the Ninth International Medical Congress will be conducted in the "most liberal and enlightened manner" by the "present able and judicious Committee of Arrangements," the progress of another week presents a wide-growing distrust of the recent work of the Committee at Chicago. The withdrawal of the appointees of the Committee in Philadelphia, Boston, Baltimore, and Washington has been followed by similar resignations in Cincinnati, St. Louis, Chicago, and in other localities. These declinations have come not only from the gentlemen originally appointed by the first Committee, but, in a number of instances, the appointees of the present Committee respectfully decline to hold the honors awarded them. Indeed, it seems to be quite apparent that the gifts of this Committee will go begging unless some unseen power is raised up to prop its waning fortunes. Under existing circumstances it seems clearly the duty of this Committee to abandon its work of reorganization as the most graceful and practical solution of the difficulties which embarrass it. By such a course the Committee would in no sense lose the respect of the American profession. It has been placed in a false position by the American Medical Association. It has been called upon to perform a duty which no similar Committee of the Association can perform under existing circumstances. The present status of the Congress is the result of a false and unnecessary issue which can work no good to the American profession or to the American Medical Association. Its introduction into this discussion was totally unwarranted and unjustifiable. The "Code issue" is not an issue which should be raised in the organization of an International Medical Congress. At previous meetings of the Congress all questions of medical politics have been rigidly excluded, and such should have been the case in the organization of the present Congress.—*Maryland Medical Journal*, August 1, 1885.

The Cholera in Spain.—The National Board of Health publishes the following figures: Cholera in Spain from March 4, date of reappearance, to July 4. 1885.

Province.	Cases.	Deaths.	Per cent. of mortality.
Alicante	1,588	646	40.6
Castellon	2,617	1,277	48 8
Cuenca	78	40	51.3
Madrid	1,700	753	59 2
Murcia	6,007	2,319	38.6
Taragona	31	19	61.2
Teruel	12	5	41.6
Toledo	455	207	45.5
Valencia	14,928	6,851	45.5
Zaragoza	628	280	44 7
Totals	28,044	12,347	....

The Composition of Kentuckians.—The last census reports show that the men and women of Kentucky are the tallest in the world, owing, we doubt not, to their good doctors and the blue-grass whiskey, which reminds us of the observation of an acute physiologist, who says that man is composed of one part solids and two parts water, unless he is born in Kentucky.

Mr. Erichsen's Political Candidature.—Mr. Erichsen is the Liberal candidate for the representation in Parliament of the Universities of Edinburgh and St. Andrews. The *British Medical Journal* says that the presence in Parliament of a certain number of members of the medical profession, accustomed to consider social questions such as those which urgently call for treatment in the next House of Commons, is very generally felt. Mr. Erichsen's return will largely depend upon the efforts of his medical friends and the support of the medical voters generally.

Students of the Berlin University.—The number of students matriculated at the Berlin University this term exceeds that hitherto attained in any preceding term. In the summer of 1873 there were only 1,590 students on the books; in 1880, the number amounted to 3,365; and this year it has reached 5,465. Comparing the figures in the Faculty of Medicine, we find 340 inscribed in 1873, 924 last year, and this summer 1,072. There are 11 students from Great Britain, and 89 from America.

Small-pox is on the increase in Great Britain.

Indian Munificence. — Maharani Surnamayi, of Cassim Bazaar, Moorshedabad, one of the millionaires of Bengal, and already well known for her munificent liberality, has given a lakh and a half of rupees toward the scheme for providing separate classes for female medical students at the Calcutta Medical College, and has promised to increase the gift to eight lakhs should a separate college be provided.

The Use of Chloroform.—In Dr. Pean's clinic, in Paris, chloroform is given with perfect safety by using an instrument which insures eight per cent. of chloroform to the air breathed. The great danger in administering chloroform is the shutting out of the necessary amount of air.

The Cholera Spreading.—It is certain now that cholera has appeared again in France, not only on the northern slopes of the Pyrenees but also in the city of Marseilles, where the mortality is from 15 to 20 a day. The daily mortality in Spain is probably not less than 1,500. It will be well for our quarantine authorities to be on their guard against all vessels arriving from Spanish or French ports on the Mediterranean. They should also be well informed about the sanitary condition of Cuban cities. News from Havana shows that while the inhabitants of that city well know that they are in danger very little has been done to prevent the introduction of cholera at that port.

The *Times* correspondent telegraphs from London, under date of August 4th, concerning the cholera in Marseilles, that the local authorities in their efforts at secrecy had decided not to open the Pharo Hospital, but two special emergency wards were fitted up in the Conception. This latter hospital is now crowded with more than twenty patients, mostly serious cases. It being dangerous to keep longer in the same hospital persons sick with other diseases, the Pharo will probably be opened to-day or to-morrow. The cases are far more serious than those of last year. The heat has been prolonged and intolerable, and the sanitary condition of the city is worse than then. There is every reason to expect greater ravages. Opinions differ widely regarding the cause of the outbreak. The common theory, that the disease was brought by Spanish refugees, is not borne out by the facts. Not one of the great host of these has died or been attacked. The doctors generally agree that either the heat developed latent germs from last year or that the disease spread from the troops at Pas de Lanciers, where there are in camp ten thousand men, and whence an average of eighty patients has been daily sent to the military hospital in Marseilles during the past fortnight—ostensibly cases of typhoid fever, but suspected to be really cholera. There is great indignation against the officials for their bungling, harmful attempts at concealment, and among the better classes at the fearful condition of the town. The issue of official bulletins will begin as soon as the Pharo is opened.

A dispatch from Marseilles, dated August 5th, says that M. Legrand, Minister of Commerce, bitterly upbraided the municipal authorities for neglecting to improve the sanitary condition of the city after the warning they received last year. The Pharo Hospital has been opened. Officers who have returned from China say the cholera is raging there, and that Admiral Courbet died from that disease. Thirty persons died of cholera here yesterday. Death follows soon after the victims are attacked. The municipal authorities are inactive and refuse to give any information as to the number of deaths. The cholera panic is increasing. Many persons are fleeing the city in dread. Over four thousand new cases of cholera were reported in Spain on August 4th. Reports from Paris say that the disease has reappeared there.

An Epidemic in an Indiana Village.—At Porter Station, a village of some three hundred inhabitants, an epidemic is reported to have broken out. The doctors appear to be unable to ascertain its true nature. The people of the village are mostly Swedes, of cleanly, thrifty habits, and until the present epidemic broke out among them they have been remarkably healthy. As uncontrollable vomiting and diarrhœa are the most prominent symptoms, the disease is probably an endemic of cholera morbus produced by tainted food, and not the mysterious epidemic which it is reported to be.

Ferrán Snubbed by the Paris Academy.—The Paris Academy of Medicine has refused to allow a long letter from Dr. Ferràn to be read before the Academy, thus virtually stamping him as an impostor.

The Siberian Plague.—It is stated that the "Siberian plague" has made its appearance in three different villages within the immedate neighborhood of Odessa. Among Russians cholera has comparatively slight terrors to those aroused by the presence of this disease, which is alike loathsome, fatal, and terribly contagious. The abnormally hot summer, such as has not been experienced during the last six years in the south of Russia, is propagating in an alarming degree many epidemics.

Suffering among French Troops in China.—Reports have reached Paris to the effect that the troops at Tonquin are suffering from "impaludism," and particularly pernicious fever, which latter is committing great ravages among the soldiers. By the last mail the total number of deaths was put down at about 100. Contrary to what has been stated in the political papers, the number of cases of typhoid fever is not greater, all things considered, than in the garrisons of France.

Poisoning from Ice-cream.—Telegrams from Rome state that two hundred persons have been poisoned through eating the ice-cream sold by an ambulant vendor of Riposti in Sicily, on the occasion of a local holiday.

The Opium Trade.—The opium treaty between England and China has been formally ratified at the Foreign Office. The chief points in the treaty are the abolition of inland barriers for opium and the adoption of a uniform tax.

The Illinois State Board of Health is now engaged in revising the "Official Register of Physicians and Midwives." Any notification of changes, omissions, or errors will be regarded as a favor, as the Board wishes to make the coming register as correct as possible. Address Secretary State Board of Health, Springfield, Ill.

A French Hospital in Yokohama.—A French hospital has recently been founded at Yokohama. It is specially intended for the sick and wounded of Formosa. About a hundred soldiers have already been treated there, exclusively by French physicians.

Gerhardt to be Frerichs' Successor at Berlin.—It is now definitely settled that Professor Gerhardt, of Würzburg, will succeed to the chair of clinical medicine at the University of Berlin, made vacant by the death of Professor Frerichs. Professor Leyden will also continue in charge of his medical clinic. Both clinics will henceforth be maintained on a basis of complete co-ordination. The former designation of first and second medical clinic is to be dropped.

One Doctor Sues Another.—Dr. George P. Bartlett, one of the Board of Pension examining surgeons, of Boston, has brought suit against Dr. E. N. Whittier for $10,000 in an action for libel, and has caused Dr. Whittier's property to be attached. The libel consists of charges against the character of Dr. Bartlett, including statements that he was implicated in the Dr. Azel Ames case, and that he was discharged from the position of medical examiner for the Travellers' Insurance Company, at Woburn, because of being a party to attempts to swindle the company by practising graveyard insurance. Dr. Bartlett has retained General Butler and Mr. Washburne as counsel.

Trained Nurses for Rheims.—A school for the instruction of male and female sick nurses has just been founded at Rheims. The courses of instruction will commence in October.

Charity Hospital.—Dr. Charles W. Allen has been appointed a member of the Medical Board of the above institution, vice Dr. H. G. Piffard, resigned.

HOW CAN THE WASHINGTON INTERNATIONAL CONGRESS BE RESCUED FROM FAILURE?

An Open Letter.

To Dr. John V. Shoemaker, Secretary of the Committee of the American Medical Association for organizing the Ninth International Medical Congress at Washington in 1887.

Dear Sir: Having been appointed by the committee of which Dr. Billings was chairman to be the president of the Ophthalmological Section of the International Medical Congress, to be held at Washington in 1887, and having accepted its duties and begun to perform them, I think it becoming that I should report to the committee which has superseded the one from which my commission came, what I have done, and state my views upon the method of conducting the proposed Congress which the American Medical Association adopted at its last meeting in April and May. This method is a signal departure from the original plan, and I must avow that with its conspicuous and essential features I cannot concur, and I think it my duty to declare myself openly both to the committee and to the medical profession.

I attended the Congress at Copenhagen in August, 1884, and entered heartily into the scheme for bringing the next meeting to the United States. In September following I attended the annual meeting of the Ophthalmological Congress at Heidelberg, and at their banquet I publicly urged the members to join us in the Congress at Washington. I also took occasion, in private intercourse, to present this invitation to many ophthalmological colleagues. In December following, while living in Switzerland, I received notice of my appointment as President of the Ophthalmological Section. From that time I officially called attention of medical men to the subject in various cities of Germany and Switzerland, in Paris, and in London. I found a ready and enthusiastic response in favor of coming. I also discussed, with some distinguished men, the topics in ophthalmology which should have special consideration, and some of them agreed to prepare papers on particular subjects to be read at Washington.

The International Medical Congresses, of which the last two were held in Copenhagen and in London, are composed of persons who come together as individuals, not representing societies nor universities, but simply as individuals who have a common interest in scientific and practical medicine. Each Congress is an aggregate of units, *not an assemblage of delegates*. It has power to perpetuate itself, and it recognizes no other organization. The medical men of the city and country where it meets combine together in a suitable organization to prepare for its accommodation, both in reference to its business and to its social entertainment. They unite as organizers and hosts. When the Congress has adjourned and the transactions are issued, their organization is disbanded forever. They do not pretend to any power to decide who shall be members of the Congress, either domestic or foreign. For proof of these statements it is only needful to make inquiry of the leading men of the Congresses in Copenhagen and in London. When, as a private individual, I invited my colleagues at Heidelberg, and when afterward in my official capacity I pressed other medical men in other places, to come to us in 1887, they necessarily assumed that in the United States the Congress would be of the same composition and formed on the same basis as were the previous eight Congresses held in Europe. They had also been told by the committee of invitation at Copenhagen that if they came they would have a national greeting, and be the guests of the whole medical profession of the United States. By its committee the American Association declared that it simply assumed the honor of speaking the words of invitation, which were intended to voice the welcome of the whole profession of the country. At Copenhagen, and among all with whom I have had intercourse on this subject since that meeting, I know that this has been the understanding. In the list of officers chosen by the committee of which Dr. Billings was chairman I recognized this broad and liberal spirit. At the same time, in the rules adopted, the principle of delegate membership was introduced, and made applicable only to American members. This circumstance was pointed out to me by European physicians as something new and strange. This infraction of previous custom has opened the way to mischiefs which have followed. The idea of delegate membership was stringently pressed at the last meeting of the American Medical Association. It was also declared that only members of this Association and of such other bodies as it deemed to be in affiliation with it should participate in the Congress. As a result of this decision the committee of organization was reconstructed, and in carrying out the manifest wishes of the Association, it dropped from the lists of officers the names of certain men. The men thus held up to obloquy were not declared to be unfit because of lack of capacity, or because of deficient scientific attainment. They were simply distasteful to the feelings of a majority of the Association. They had been more or less conspicuous in a recent controversy, whose embers were smothered but not extinguished. The marked distinction conferred upon the medical gentlemen, who by being lopped off have been held up conspicuously to the view of Europe and the United States, may have been meant to be retributive. I trust that the sober second thought of the American

Medical Association will realize that if by putting these gentlemen into their present position any disgrace has been incurred, it certainly does not attach to them.

For my part, I cannot acquiesce in a policy which leads to these results, nor can I do violence to my sense of right by abetting such exclusions. If the intrusion of the delegate idea into the Washington Medical Congress is an unwarranted innovation, and subversive of the previously uniform composition of the International Medical Congresses, we have the strongest reason to rectify our course when we see that the outcome of it has been to cast reflections upon men who are among the brightest lights and best workers in the profession. The baleful influence of this course is beheld in the numerous withdrawals from appointments to office, and from participation in the Congress, which have since taken place.

But it may be thought that enough able men will remain to present a sufficient and capable body of American physicians to welcome our European friends. *Are we likely to have any European guests under existing circumstances?*

Read late numbers of the London medical journals, which naturally are the first to take note of American events. Especially peruse an article from the *London Medical Times and Gazette* of July 17th, which was sent to me by the editor when I left Queenstown on my return home. Its important parts have appeared in the New York Medical Record and in the *Philadelphia Medical News* of August 1st. The whole article is reprinted in the *New York Medical Journal*, August 1st, p. 139. It recites the facts to which I have referred; and its comments, pungent and stinging, will not be flattering to our pride. It is entitled, "The Washington Congress in Danger." It points out that the "danger" arises from the maintenance of old controversies and of old ill-feeling. I quote this pregnant sentence: "*We feel sure that a very large majority of English and Continental practitioners will refuse to cross the water if this understanding* (not to raise the Code question) *is not rigidly kept to.*" We know that it is not easy to persuade the medical men of Europe to cross the sea to attend a meeting. Most certainly their reluctance will become refusal, if they are to be landed in the midst of contentions, and are cut off from seeing many of the physicians whom they would expect to meet. They, like all gentlemen, shrink from complicity in broils, however ready they may be to enter into scientific debate. We shall shut out invited guests by closing the doors against our own brethren with whom we differ on matters absolutely irrelevant to the purposes of the Congress.

As an illustration growing out of my own endeavors, let me refer to the ophthalmological section. In the printed schedule of March 24, 1885, I find my name as president (page 21) associated with two eminent men as vice-presidents, and with thirteen other gentlemen as a council, who are not less eminent. They represent all sections of the country except the Southwest, and this omission I pointed out to the committee. The changes made by the present committee (see New York *Medical Journal*, July 4th, p. 19), are as follows: One of the vice-presidents is made president—and I cheerfully accord to Dr. E. Williams, of Cincinnati, the right of precedence, because he is the veteran scientific ophthalmologist of the country—my name comes first among the vice-presidents, and there are two others associated with me, both of them distinguished, viz., Dr. Thomson, appointed by the former committee, and Dr. Holmes, of Chicago, newly appointed.

Instead of thirteen members in the council, the new committee have appointed nineteen, and they omitted to reappoint Drs. Agnew and Knapp, of New York, and Dr. Jones, of Chicago, who were upon the council appointed by Dr. Billings' committee. Can any men among us be found of more distinguished merit than they? All are professors in well-known medical schools. The first two are in the front rank the world over, and Dr. Jones needs no praise from me. Was the reason for the rejection of these men one which the committee would like to publish in Europe? What has since followed is most painfully suggestive. Of the officers in the ophthalmological section appointed by the new committee, the following have to this date, August 1st, declined to serve, viz., the president, Dr. E. Williams, of Cincinnati; the second vice-president, Dr. Thomson, of Philadelphia; the secretary, Dr. Burnet, of Washington; of the council, Dr. H. Derby, of Boston; Dr. Norris, of Philadelphia; Dr. Theobald, of Baltimore; Dr. Wadsworth, of Boston; Dr. H. W. Williams, of Boston, and Dr. W. W. Seely, of Cincinnati, have resigned. That is, nine officers have withdrawn, and three who had been officers, were cut off. I declare freely that without these men the ophthalmological section will be robbed of its brightness. But the whole has not been told. The American Ophthalmological Society, at its late meeting, passed the following resolution by a vote of 24 to 12.

"*Resolved*, That it is the sense of the American Ophthalmological Society that the action of the American Medical Association at its late meeting in New Orleans, and of the enlarged committee appointed at that time to make arrangements for the International Medical Congress, in overturning much of the carefully planned work of the original committee appointed at Washington for the same purpose, was unwise and not to be defended, unless, possibly, upon technical grounds; and this Society hopes that none of its members will indorse the action of the enlarged committee by accepting official positions at its hands."

Not intending to assume that there are not many competent ophthalmologists in the country who are not members of this society, it is self-evident that under existing conditions the Washington Congress can have only the ghost of a section of ophthalmology. With the excisions and withdrawals of our ophthalmologists and of other medical men can we still offer inducements powerful enough to bring to us the men we want from Europe? Can I explain to my confrères in Germany, Switzerland, Paris, and London, who expressed their intention of coming and who loaded me with hospitalities—can I account for these withdrawals and exclusions in any way which will not bring disgrace upon our medical profession?

The situation is profoundly critical and failure is certain unless an absolute reversal of the present policy is quickly effected. The delegate idea must be abolished. The pledges given at Copenhagen must be carried out in good faith to the letter. This means that men who have been treated with indignity must be invited back. To do this is not pleasant to human nature, but it is manly, and it is imperative. The Congress must be free to all physicians of honorable standing. Better to have a sprinkling of unworthy men, or of irregulars, than to persist in the mischievous and suicidal course now causing disintegration. Nor can we long delay. To wait until next May is to multiply difficulties and aggravate evils. The officers of the American Medical Association and the new committee should take the responsibility of such measures as will be radical enough to restore confidence, to bring back harmony, and to counteract the distrust which will spread through Europe most rapidly and be counteracted very slowly. I have at present nothing to say about the course which I shall pursue. I have striven sincerely for the success of the Congress and I make this effort also in its behalf.

I remain your obedient servant,

Henry D. Noyes, M.D.

233 Madison Avenue, New York,
August 1, 1885.

Don't Roll Manuscripts or Periodicals.—This excellent bit of advice is at present being circulated, and the wider it goes the better.

Reports of Societies.

British Medical Association.

FIFTY-THIRD ANNUAL MEETING,

Held at Cardiff, on Tuesday, Wednesday, Thursday, and Friday, July 28, 29, 30, and 31, 1885.

(DIRECT CABLE TO THE MEDICAL RECORD.)

(Continued from page 132.)

THURSDAY, JULY 30TH—THIRD DAY.

AFTER a meeting of the Council at 9.30 A.M., the Third General Meeting was held in the Assembly Hall, and the

ADDRESS ON SURGERY

was delivered by MR. JOHN MARSHALL. The speaker undertook a comparison of the surgery of 1843 with that of 1883, and made especial mention of the methods employed by Mr. Liston at the former period. He said that epithelioma was more common in hospitals now than forty years ago, but he would not have it inferred that this proved an increase in that disease. On the same principle it might be claimed that strictures were more common now, since they were oftener seen by hospital surgeons. He spoke of Liston's skill in operating and the wide range of its application, operating for strabisums, staphyloma, and cataract.

Septic diseases were much more common forty years ago. Accuracy in physical examination was less, there being no laryngoscopes, ophthalmoscopes, thermometers, sphygmographs, etc. Still, the urine was carefully examined for albumen, the breathing, the pulse, and other objective symptoms noted with even more care, perhaps, than now. Though the microscope was but little used, yet cancerous tumors were correctly diagnosticated. Forty years ago very much less attention was paid to the hygiene of the patient, the wards were crowded and ill-ventilated, the closets were not separated from the wards, and the drains not trapped. The diet, also, was much worse. Along with modern improvements the cost of treating the individual patients was increased. The practice of antiseptics, especially, was an expensive one. In the University Hospital this item alone amounted to over $6,000 a year. On the other hand, the stay of patients in hospitals was shortened. Among the striking contrasts between the treatment of 1843 and 1883 was that of simple fractures. These, which used to be leeched violently, are now simply put up in starch-dressings. Inflammatory strictures used to be much leeched. Ulcers of the leg were treated with water-dressings. The use of iodide of potassium for periostitis, so much advocated now, was then just beginning. Many cases of bone caries from syphilis were observed, and some of these cases died. Mr. Liston's particular pride was in his plastic operations. In those days few wounds closed by first intention. Erysipelas and pyæmia followed the best operators. Hygiene was forgotten, and patients were dosed with mercury. Anæsthetics now encourage many more patients to undergo operations than was formerly the case.

At the close of the address Mr. Erichsen moved a vote of thanks, which was adopted.

The reports of the Council on Medical Reform and on Parliamentary Bills were presented.

In the

SECTION ON MEDICINE

papers were read by Dr. F. W. Pavy on "Cyclic Albuminuria (Albuminuria in the Apparently Healthy);" by Dr. E. Markham Skerritt on "Cases Illustrative of Rupture of the Pulmonary Air-vesicles;" by Dr. J. Tatham on "The Registration of Cases as carried out at the Hospital for Chest Diseases and Consumption, Brompton, and the Investigations Proposed to be Specially Worked Out;" by Dr. W. R. Thomas on "A Few Remarks on the Influence of Malaria on the Progress of other Diseases;" by Dr. S. Wilks on "A Case of Simple Stenosis of the Œsophagus, with a Specimen," by Mr. Lockhart Stephens on "A Rare Form of Congenital Heart Disease;" by Dr. C. R. Drysdale on "The Treatment of Syphilis and the Alleged Prevention of Tertiaries," and on "The Hygienic Treatment of Syphilis."

In the

SECTION ON SURGERY

MR. FREDERICK TREVES introduced the subject of

OPERATIVE INTERFERENCE IN INTESTINAL OBSTRUCTION.

The discussion which followed was shared in by Mr. Greig Smith, Alfred Eddowes, A. W. M. Robson, Mr. Pughe, and Dr. Cousins.

Papers were read by Mr. Robson on "A Case of Enterectomy for Acute Intussusception, also a Series of Surgical Cases illustrating the Use of the Eucalyptus-air and Dry Dressings;" also by Mr. E. Stanmore Bishop on "Enterorrhaphy, with a Description of a New Suture;" by Mr. Edward Owen on "Caries of the Cervical Vertebra;" by Mr. H. L. Snow on the "Non-heredity of Cancer;" and by Mr. C. B. Keetley, on the "Radical Cure of Hernia by Injection."

FRIDAY, JULY 31ST—FOURTH DAY.

In the

SECTION ON PUBLIC MEDICINE

an address was delivered by the President, MR. T. J. DYKE, in which he dwelt upon the remarkable progress which sanitary science had made, especially with reference to our knowledge of disease-germs and the methods of destroying them. The thanks of the Section were voted, on motion of Dr. Paine, seconded by Dr. Drysdale.

In the

SECTION ON MEDICINE.

the reading of papers was resumed by Dr. Sidney Coupland on "Gangrene of the Lung;" by Dr. T. D. Griffiths on the "Causes of the Localization of Tubercle in the Apex of the Left Lung;" by Mr. A. J. Harrison on "A New Method of Treating Tinea Tonsurans;" by Dr. Prosser James on "Pancreatic Digestion."

In the

SECTION ON SURGERY

further papers were read, by Mr. Bernard Roth on "Two Hundred Consecutive Cases of Lateral Curvature of the

Spine treated without Mechanical Supports;" by Mr. J. Brindley James, on the "Treatment of Lumbago and Rheumatic Pains by his Special Percuteur;" by Dr. C. B. Ball on "Melanotic Sarcoma of the Rectum;" by Dr. Hugh Miller on "Two Cases of Recurrent Placenta Prævia;" by Mr. T. E. Cahill on "The Latest Surgical Dressings."

In the

SECTION ON OBSTETRICS

the subject of the "Mechanism and Treatment of the Third Stage of Labor" was introduced by Dr. Berry Hart and discussed by the members. Papers were then read by Dr. J. Braxton Hicks on "A Condition of the Inner Surface of the Uterus after Delivery of the Child of Practical Importance." Mr. G. Padley reported a case of acute abscess of the unimpregnated ovary, with recovery by absorption; also a case of accidental rupture of an ovarian cyst, with recovery without reaccumulation.

Papers were also read by Dr. Barbour and Mr. Davies.

In the

SECTION ON PUBLIC MEDICINE

Dr. S. H. Wright made some remarks on the present management of the Medical Service, and papers were read by Dr. Roberts, Dr. Drysdale, and Mr. James.

In the

SECTION ON THERAPEUTICS

a discussion was held on anæsthesia.

At the last general meeting the reports of the various committees on Collective Investigation, Scientific Grants, and Habitual Drunkards were read.

There were about five hundred members present.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 27, 1885.

John A. Wyeth, M.D., President, in the Chair.

(Continued from p. 110.)

POTT'S DISEASE IN A CHILD FIVE YEARS OF AGE, WITH NECROSIS OF ALL THE PRINCIPAL LONG BONES.

Dr. William Perry Watson presented a specimen in which the curvature cervico-dorsal was at nearly a right angle, and yet no symptoms of paralysis. Death from pneumonia.

Gertie S——, aged five years and two months. Her mother was an American and her father a Spaniard. There is no specific history in either. Gertie was bottle-fed. Her first tooth appeared when she was one year old, and her mother says the anterior fontanelle closed about that time. She walked when eight months old. When she was about one year old, a swelling about half the size of an orange appeared on the inner aspect of the lower third of the right thigh. This is said to have entirely disappeared under the use of poultices. From the time she was able to sit up until she was two years old she was accustomed to sit on a counter in a store, by the window, day after day, and look at the passers-by. The lower limbs did not hang over the counter. Her mother thinks the curvature of the spine was produced by this prolonged position, as it was about this time that she first noticed the kyphosis. The mother is quite positive that she never received any injury either from a fall or a blow.

About two years ago she was brought from Syracuse to Jersey City, and came under my observation. At this time the curvature was very marked and could be quite, if not wholly, obliterated by extension and counter-extension. There was also a cold abscess on each wrist-joint, and one on inner aspect of lower third of right thigh. She was walking well and showed no evidences of paralysis. Stillman's backward-traction apparatus was applied, and worn, to her marked relief, for about two months, when a synovitis of the right knee-joint prevented her from walking. In March, 1884, she was admitted to the Daisy ward (for sick children) of Christ Hospital. In June following, she was placed in Meigs' case apparatus, by which she was made more accessible to the fresh air, which, together with cod-liver oil and iron, made a very marked improvement in her general condition. In October following, the right knee-joint with lower third of femur was exsected, as well as the lower third of right radius.

The amount of reparation taking place in six months is shown in this specimen.

In this portion of the vertebral column the absorption of the bodies of the fifth, sixth, and seventh cervical, and first and second dorsal vertebræ is very marked.

The small amount of compression of the cord for so marked a curvature is remarkable.

Dr. J. F. Ridlon had in two cases applied traction according to the method proposed by Dr. Brown, that of putting the child in bed and making counter-extension from the pelvis and shoulders by some fixed apparatus attached to the bed, and by weight and pulley when the lesion was high up. In one case the deformity was removed entirely in two weeks. In the other case the treatment was continued two months, when it became necessary to apply Taylor's instrument. He had been very favorably impressed with this method where considerable deformity seemed to be maintained by muscular spasm rather than by disease of the bone.

The President said that extension in the dorsal decubitus had proved satisfactory in one case under his observation, that of a man twenty years of age, in whom the third, fourth, and fifth cervical vertebræ were involved with partial subluxation. He had paraplegia, which was relieved completely until the patient became restless and uneasy, and the parents removed him from the hospital.

Dr. L. H. Sayre had seen some cases in which the patients had been kept for a long time upon the back without extension, and the deformity had steadily increased. He had seen a number of cases benefited by the same treatment which had been mentioned by Dr. Ridlon and Dr. Wyeth, that is, by extension in the horizontal posture. In small children, where the pelvis is not sufficient to give the required support, he had been in the habit of keeping the patient for some time in a wire cuirass with a jury-mast, and in this way had been able to make traction sufficient to relieve the symptoms and permit of the child being taken out into the open air.

The President remarked that when he first heard of Meigs' case apparatus he visited him and spent several days in examining it, and was very much pleased with its use, especially where the head was suspended, particularly for high deformities. He thought it was not so well adapted for the lower deformities.

Dr. Ridlon asked concerning experience of the surgeons present in the use of chin-pieces—if any had been annoyed by the pieces slipping back and cutting the trachea.

Dr. Sayre remarked that the trouble with chin-pieces, as ordinarily made, was that they did not fit the chin. Often the cup was not sufficiently deep to prevent it from slipping back, and that it was necessary for the chin-piece to be made specially for each patient, and that its fit should be supervised by the surgeon, and not by the instrument-maker.

Dr. Watson also presented a specimen which enabled him to give the history of a case in which there were

THREE SINGLE AND FOUR TWIN PREGNANCIES IN SIX YEARS.

Mrs. C——, English, aged twenty-eight, married six years, a robust healthy woman, was admitted to Christ Hos-

pital on May 21st with bilateral laceration of the cervix. Gave a history of six pregnancies, two children living. In the first she miscarried at the sixth month with twins; in the second she went to full term with one child; in the third she miscarried at the third month with twins; in the fourth she miscarried at the fourth month with twins; in the fifth she went to full term with one child, and in the sixth she miscarried at sixth week with twins. When admitted to the hospital she stated that she had menstruated on March 27th and on May 1st, and normally. On May 21st the right side of cervix was closed with two sutures, and the left with four, after which the sound was passed into the body of the uterus. The case progressed favorably, and on May 25th all the stitches were removed, soon after which there was some hemorrhage which was thought to come from the track of a suture, although both sides were still coaptated. In the evening she had labor pains, and during the night expelled the fœtus shown. Examination to-day, the 27th, shows the right side of cervix closed, while the left side is in about the same condition as previous to the operation. In this pregnancy, making the seventh in six years, she miscarried at sixth week with one. That all these miscarriages were not induced, excepting the last, where there was no reason to expect impregnation, is believed by the medical attendants, and yet their course is not apparent. There is no specific history either in the patient or her husband.

Dr. C. C. Lee said he had been very much interested in what Dr. Watson had stated concerning the patient with unusual fecundity. In a case which exhibited such extraordinary fertility it was almost impossible to avoid such an error, and doubtless many such cases occurred without ever being reported.

Dr. Watson said that the only sign which was even suspicious was the fact that the uterus was deeper than normal after sewing up the cervix and introducing the sound. But there was no evidence whatever of the nature of the case until four days after the operation and the introduction of the uterine sound.

Dr. W. P. Northrup presented a microscopic slide illustrating

INTRAMENINGEAL HEMORRHAGE.

A child, aged forty-four hours, was born in New York Foundling Asylum. Forceps; presentation vertex; labor accomplished after a long, hard pull; suspended animation, recovery; crying, convulsions for twenty-four hours; death.

Autopsy, April 7, 1885.—Body: Eight pounds, no abnormalities. Brain: Meningeal hemorrhage, blood over all circumference except anterior superior portion, most in posterior and middle fossæ; none in ventricles. Hemorrhage about beginning of cord; none in substance of brain. Lungs: Posterior portion of both firm, red, sink in water; anterior lighter in color, softer, aerated; there is found to be hemorrhage into the tissues everywhere—into alveoli, into septa, into connective-tissue about vessels. Kidneys: Hemorrhage into suprarenal bodies, and about right kidney; none into the organ.

The specimen under the microscope shows the hemorrhage into the pia mater. The blood is in the membrane—intrameningeal. The specimen shows the outer layer of the pia mater widely separated, the inner layer lying against the brain substance, the space containing blood.

Running down into the brain is a sulcus in which the pia mater is separated into two layers, and between them is blood. An artificial injection of the lymph-spaces has been well accomplished by rupture of the fine vessels of the membrane itself.

Dr. Northrup also presented a specimen with the following history:

DIPHTHERIA (CROUP)—PNEUMONIA—INTERSTITIAL EMPHYSEMA—CONVULSIONS.

Female, three years five months of age, inmate of New York Foundling Asylum, became croupy ten days before death. On autopsy an exudate of pus and fibrin was found in the larynx. Emphysema (interstitial) in the anterior lip of one lung, and a small mass of pneumonia of posterior portion.

Child had suffered from severe dyspnœa and died in convulsions.

The specimen is an antero-posterior section of the whole lung, showing emphysema and pneumonia. It also shows one of the uses of *celloidin*. The whole half lung, including the root, is one firm mass.

Dr. C. C. Lee remarked, concerning Dr. Northrup's first specimen, that he had no doubt that accidents of this kind occurred very much more frequently in cases where children were delivered with forceps than was usually supposed in the absence of autopsy. He then mentioned a case which he saw in consultation, and in which the head of the child had been dragged directly against the arch of the pubes with the forceps, and in which it was delivered with the use of only a moderate amount of force when the position of the woman was changed so as to correct the inclination of the pelvic contents. The child was resuscitated and its head was carefully examined, and there was no depression or evidence of fracture, but within thirty-six hours, having been quite well up to that time, it gave evidence of clonic convulsions, and died within a few days with symptoms of increasing compression, without the evidence of depression of the cranial bones.

Dr. John F. Ridlon presented a specimen of

THROMBOSIS OF THE LEFT CORONARY ARTERY—INTERSTITIAL MYOCARDITIS—FATTY DEGENERATION WITH DILATATION OF THE HEART,

accompanied by the following history: A man, about fifty-five years of age. General health always good, with the exception of dyspeptic symptoms, from which he had complained for twenty years. It was his custom to dine moderately about six, drinking a pint of light red wine, and take a light lunch with a glass of wine just before bedtime, between eleven and twelve o'clock. Two hours later he would wake up with a fluttering at the pit of the stomach and a peculiar anxious feeling, which would keep him awake two or three hours. Indiscretions in diet and mental worry would aggravate this condition. At times he was free from it. The patient came under my care three years ago. I believed the symptoms to be dyspeptic, but found no result from treatment extended over many months. I several times listened to the heart-sounds but detected nothing abnormal. I last saw him professionally about eighteen months ago, since which, up to his last illness, he was in unusually good health and did not require the advice of a physician. On the morning of April 30th he was in his usual health and went out to visit his pupils. About noon he felt some distress in his stomach, and went into a drug store and took a little bicarbonate of soda in some Vichy. Soon afterward he felt faint, and vomited. He was taken in charge by Dr. A. P. Dudley and taken home. He complained of pain about the pit of the stomach (or heart), and the pulse was very weak. Dr. J. H. Emerson saw him in consultation, but I do not think a diagnosis was arrived at. At about 3 P.M. the pulse stopped, and Dr. Dudley, believing him dead, left him. A few minutes later, however, he revived, and was seen by Dr. C. C. Lee, who gave some brandy by hypodermatic injection. Later Dr. Huntington Richards was called, and him I found on my arrival at 5 P.M. The pulse was very small and weak; the skin was covered with cold perspiration; he tossed about the bed and moaned, holding his hand over the pit of his stomach and heart to locate the pain. A soft, blowing murmur could be heard with the first heart-sound, and was very suggestive of the so-called anæmic murmur. He was given brandy and digitalis hypodermatically, and a blister put over the heart; and he had cracked ice and Vichy. The condition improved, but the pain continuing six drops of Majendie's sol. morph. was given. From

then he no longer complained of the pain and dozed at times. At 7 P.M. there was vomiting, the patient insisting upon going to the stationary basin, being able to walk unaided. At 11 P.M. the heart's action was stronger, the skin drier and warmer, no complaint of pain, and patient sleeping most of the time. At 3 A.M. he asked for and took a cup of beef-tea, but soon vomited it. At 7 A.M. he professed himself much better and got up for a glass of water. At 7.30 he was found dead. The autopsy was made by Dr. Frank Ferguson thirty-two hours later. The body was rigid (it had been on ice) and well nourished. There were a few adhesions between the lungs and the chest-wall. A small mass of tubercle was found at the apex of the left lung. There was some congestion in the posterior portion of both lungs, but little œdema. The heart was very large; it seemed almost large enough to put a normal heart inside of it; there was some roughening of the valves of the left heart, but nothing to cause insufficiency except the dilatation. In the left coronary artery, about an inch and a half down, was found a clot completely plugging the vessel for half an inch; the muscular tissue of the heart beyond this was deeply congested. A certain amount of interstitial myocarditis was found. The stomach seemed very nearly normal but contained about four ounces of blood. The liver, spleen, and kidneys were all enlarged and pale. Dr. Ferguson will report on the microscopic appearances.

MULTIPLE ABDOMINAL TUMOR—FIBRO-CYST OF THE UTERUS.

DR. C. C. LEE presented a specimen which consisted of the uterus and a multiple abdominal tumor. They were removed from a quadroon, married, and twenty-six years of age. When Dr. Lee saw the patient first she stated to him that she had some obscure tumor in the abdomen; that she had consulted several doctors, all of whom said that it was not due to pregnancy, she believing that she was pregnant. The patient was extremely feeble, was naturally a delicate woman, and was in a condition which rendered her very unfavorable for an extensive surgical operation. Dr. Lee diagnosticated an ovarian tumor, although he had never seen a pure ovarian cyst in this race. She entered his service at the Woman's Hospital where he attempted to remove it, and found that the growth involved the uterus, and that he evidently had to deal with a multiple tumor which had begun probably as a fibro-cyst and undergone colloid and partial cystic degeneration. At one point there was evidence of dermoid complication, as there were found a few hairs and slight bony formation. The operation necessitated the removal of the uterus, which was done in the usual manner. Although the patient was very feeble she had not yet had any bad symptoms. To be sure she had not yet passed through the most dangerous period for the development of septicæmia, that is from the sixth to the tenth day, yet there had not been a single trace of evidence looking toward the development of this complication. The specimen illustrated, first, that multiple tumors occurring in the negro race were very apt to be fibroids or fibro-cysts, and, second, that even in a feeble woman it was unjust not to give the patient the benefit of the doubt of a surgical operation.

EXCISION OF THE HIP-JOINT.

DR. L. H. SAYRE presented the remains of the head of the femur, together with the débris taken from the ilium in a case of morbus coxarius, accompanied by the following history:

Florence S——, aged eight years, of Wichita, Kas. Mother has always enjoyed moderate health; father's health poor, several of his family dying of consumption, himself being also somewhat affected, being unable to follow his calling, that of a physician, and compelled to seek other employment.

This little child is the only one the mother has ever borne, and has always been weakly, its birth occurring prematurely between the seventh and eighth months.

She first commenced to complain of her knee when she was not quite three years of age. Previous to this the grandfather had noticed that the child seemed weak in her lower extremities, and advised them to put her in short clothes as soon as possible so that she could move her legs more freely.

This pain in her knee went on during all the summer. The family physician, although afraid of hip disease, confined his treatment to constitutional measures. In October of the same year it became so painful that she could not walk at all. She was then taken to Dr. P——, of Johnsonville, Ill., who pronounced it hip-disease, and treated her in the horizontal posture with extension applied to the right limb by weight and pulley, counter-extension being secured by a bag of shot between the legs, against which the buttocks rested. This treatment was followed out faithfully for five months, at the end of which time she seemed to be perfectly cured. This brings us to the following April. She was up and running around from April until the following October, but as soon as the cold weather set in she again commenced to complain of her knee. She was at once put back to bed again, and remained there until the next February, 1882; and while in this condition the hip (as the mother states) became dislocated.

In March, 1882, the mother took her to St. Louis to see Dr. L——, for the express purpose of having an operation performed. The doctor, however, would not operate, but placed her in bed with extension. She remained there for three weeks. The mother becoming impatient took the child home again.

In July of 1882 an abscess formed at the upper and anterior part of the thigh; Dr. C——, the family physician, treating her in the meantime with extension and general constitutional treatment. In August of the same year the abscess closed up, and she suffered severely from blood-poisoning, which lasted for nearly two weeks, the child not being expected to live.

In January, 1883, the mother took her to the Eureka Springs in Arkansas, her condition then being very low. She remained there seven months, taking electric baths, vapor baths, etc. She seemed to be benefited by this treatment. In the following June she returned home, and had a brace made for her in St. Louis, the mother applying it when it was received. This brace, however, pained her so that she could not wear it for more than a week, when it was thrown on one side. While she was at the Springs two large abscesses appeared at the upper and outer parts of the thigh. Shortly after another abscess formed on the inner side of the thigh, over the adductors, and yet another made its appearance shortly after, making in all five sinuses, and as soon as the child was able to be moved they brought her on to me.

At the time she was brought to me the right thigh was flexed across the upper third of the left thigh, it was impossible to get at the adductors; the knee was also flexed at an angle of almost 45°. Three sinuses were discharging, and the remaining two were temporarily closed; the least movement of the leg caused intense pain; the trochanter major riding high up on the dorsum of the ilium. After a careful examination it was decided that if anything could be done there was nothing left but excision and subcutaneous division of the adductor muscles. Her health at this time was fair; the mother stated it was better than it had been for years, and was very anxious for an operation, saying she would rather take her back dead, if the operation proved too severe, than return with her in her present terrible condition.

On May 15th I performed exsection of the hip-joint, Drs. Bryant, Van Bibber, Devlin, and Woodbury assisting.

The patient being placed under an anæsthetic, I commenced my incision from a point midway between the trochanter major and anterior iliac spine, passing downward and outward in a curved direction about six inches, extending through the soft tissues down to and through the thickened periosteum of the femur. The head, neck,

and trochanter major and minor were absorbed; the dead bone being plainly visible was pushed up and cut off, with the bone forceps, about two and one-half inches below the trochanter major.

The acetabulum was carious and perforated, a large amount of débris being scraped out from it and also from the ilium, where necrosis extended within three-quarters of an inch of the anterior superior spinous process, and more than half way down the ramus of the pubes; the detritus being scraped out with a Langenbeck's scoop until the entire bony surface was bleeding and clear from dead matter.

The periosteum on the inner side of the ilium was very much thickened, as could be felt through the perforated acetabulum, and which prevented any communication into the pelvic cavity.

The femur being diseased farther down than the first incision, this was extended and an inch more of the shaft removed.

The adductor magnus and longus were divided subcutaneously and some bands of cicatricial tissue broken down, the limb being then brought parallel with the other. The sinuses were thoroughly scraped and all false membrane removed, they and the entire cavity being then thoroughly washed out with a bichloride solution 1 to 1,000. A drainage-tube was passed from the sinus on the anterior part of the thigh down through the perforated acetabulum, making its exit on the posterior part of the thigh below the gluteo-femoral crease, by way of an old sinus. A drainage-tube was also inserted on the inner side of the thigh, emerging from another sinus, the two sinuses on the outer side of the thigh being connected by my incision. The entire wound and sinuses were then thoroughly filled with balsam of Peru, and an oakum tent dipped in the same inserted in the upper portion of the wound down to the acetabulum, the lower edges of the wound being brought together with deep sutures and adhesive straps. A large compress of oakum was placed around the thigh, and firm compression made by means of a roller bandage, after which the child was placed in the wire cuirass and dressed in the ordinary manner. No hemorrhage occurred worthy of mention, and the child recovered well from the anæsthetic with very slight shock. Since date of operation the little patient has progressed favorably, temperature not being over 100°, except on the fourth day, when it reached 103°, due to obstinate constipation, which being relieved the temperature fell to nearly normal.

The Society then went into executive session.

THE AMERICAN OPHTHALMOLOGICAL SOCIETY.

Twenty-first Annual Session, held at the Pequot House, New London, Conn., Wednesday and Thursday, July 15 and 16, 1885.

DR. WILLIAM F. NORRIS, OF PHILADELPHIA, PRESIDENT, IN THE CHAIR.

WEDNESDAY, JULY 15TH—FIRST DAY—MORNING SESSION.

DR. C. R. AGNEW, of New York, read the first paper, entitled

OPERATION FOR REMOVAL OF DISLOCATED CRYSTALLINE LENS.

The operation was described as follows: The pupil was dilated with atropia. The patient was then etherized and cocaine was applied. The eye was secured with fixation forceps. An instrument resembling a two-pronged fork, termed a bident, was introduced into the vitreous chamber behind the dislocated lens, pressing it forward. The bident transfixed the eye and held the lens in position. Section was then made in the ordinary manner and the lens removed. The eye recovered without any unpleasant symptoms. The speaker did not claim that all dislocated lenses should be removed, but this instrument facilitated the operation when it was required.

DR. DAVID WEBSTER, of New York, read a paper (see p. 143) on the

EXTRACTION OF A DISLOCATED LENS BY THE AID OF DR. C. R. AGNEW'S BIDENT.

DR. H. KNAPP thought that in these cases there was not much difficulty in removing the lens, which could often be accomplished with the loss of very little vitreous, but the danger came afterward from inflammatory complications. And where the sight was lost, he thought it better to at once enucleate the eye and thus lessen the dangers of inflammation. He considered the bident which was exhibited to be an ingenious instrument. For the last six or eight years he had not introduced an instrument within the globe to facilitate the removal of the lens. This he was able to accomplish by external manipulation.

DR. C. R. AGNEW, suggested that the bident might also be useful in the removal of foreign bodies from the interior of the eye. He did not acquiesce in the view that enucleation was a simple operation. He regarded it as a serious mutilation.

DR. C. H. WILLIAMS, of Boston, thought that there was another alternative than those mentioned, and that was evisceration of the eye, and closure of the anterior opening with sutures. This he had performed a number of times with success. He thought it better than enucleation. It gives a better stump for the artificial eye.

DR. D. B. ST. JOHN ROOSA, of New York, read a paper, on the

EXTRACTION OF THE LENS IN ITS CAPSULE.

For the past three years the doctor had been in the habit of removing the lens in its capsule, in a large proportion of cases without iridectomy. The use of cocaine had facilitated the operation. He referred particularly to the method of dislocating the lens. The section is made as usual, but large. After puncture and counter-puncture are made, the knife is turned on its back so that it rests on the iris. The knife is then moved up and down two or three times until the lens is seen to move, then the section is completed and the lens can usually be removed with no loss of vitreous. The manipulations on the cornea are made with one or two spoons. Sometimes after the operation the iris is rolled under, but in many cases the pupil is circular. The writer had performed the operation between thirty and forty times, and was satisfied with his success. If the lens is not dislocated, iridectomy may be performed and the ordinary operation practised. A paper on the subject is to be found in the "Transactions of the New York State Society," and in THE MEDICAL RECORD of February 7, 1885.

DR. GEORGE C. HARLAN, of Philadelphia, reported two cases of

SUBCONJUNCTIVAL LUXATION OF THE LENS.

In the first case no operation was recommended, as vision was good. In the second case the lens was removed. The doctor thought it well that in those exceptional cases in which vision remains the operator should think twice before resorting to removal.

DR. O. F. WADSWORTH, of Boston, reported

A CASE OF DISLOCATION OF THE LENS UNDER TENON'S CAPSULE.

The eye had been injured two weeks before the patient came under observation. There was loss of sight, pain about the eye, and irritation of the other eye; the cornea was hazy, and there was blood in the anterior chamber; the eye was enucleated, and it was found that the lens was beneath Tenon's capsule, and that it was held in this position by inflammatory tissue.

Dr. J. A. Andrews, of New York, read a paper on

THE TREATMENT OF PURULENT CONJUNCTIVITIS.

The treatment is based upon the belief that the contagious element is of the micrococcus variety. He related a case in which he had secured an inoculation of the seventh generation of a pure culture of a gonococcus. This is the first case inoculated with the gonococcus. He showed an instrument which he had devised to wash out the conjunctival cul-de-sac. It consisted of an eye speculum, with hollow arms through which fluid may be passed. He had found bichloride of mercury solution (1 to 10,000) serviceable, but apt to irritate. A six per cent. solution of boracic acid was also found efficient. A two per cent. solution of carbolic acid is useful, as it inhibits the movements of the white corpuscles. Irrigation should be maintained for ten minutes in order to remove all secretion. Nitrate of silver solution (two to twelve per cent.) is then used, and an antiseptic dressing is next applied. This consists of vaseline and boracic acid or carbolic acid; but he laid especial stress upon the importance of maintaining irrigation of the conjunctiva by means of the instrument referred to above.

Dr. Charles S. Bull, of New York, read a paper on

ABSCESS OF BOTH FRONTAL SINUSES.

The patient had been hit on the forehead fourteen years previously with a piece of wood. This produced a fracture of both nasal bones and deviation of the septum. In seven weeks the wound had closed. Ten years after the accident a swelling was noted at the upper inner angle of the right orbit which could be made to disappear by pressure. There was complete ptosis. An incision was made into the swelling just beneath the orbital margin, and a large quantity of pus escaped (two or three ounces). The cavity was washed with a five per cent. solution of carbolic acid. No connection with the superior nasal meatus could be detected, but the bony septum between the two frontal sinuses was absorbed, and both sinuses were converted into large cavities. The entire ethmoid bone was an immense cavity, the bony structure being absorbed. A number of osteophytes were removed. A drainage-tube was introduced. The patient was discharged six weeks after the operation and recovered completely. The ptosis disappeared, and the eye was restored to the normal plane.

A case of melanotic sarcoma of the orbit was reported by Dr. Buller, of Montreal, Canada.

Dr. B. E. Fryer, of Kansas City, Mo., reported a case of

BONY TUMOR OF ORBIT.

The patient, a boy six years of age, came under observation April, 1885. There was swelling of left orbit, which included the whole line of the superciliary ridge. It was quite hard. Some time before the boy had been struck by a piece of wood, but it was thought that no splinter had lodged beneath the skin. It was decided to remove the tumor. This was done, and on examination it proved to be a bony cyst within which was a small piece of wood. This was enclosed in bone on all sides. The edges of the wound were brought together, and healing resulted without complication.

Dr. W. H. Carmalt, of New Haven, Conn., reported the case of a child of ten years of age from whom he removed a small growth from the upper lid. Six weeks later the growth had returned. An exploratory operation was done, and it was found that the growth extended into the orbit, and that it was impossible to remove it entirely. It was therefore decided not to complete the operation. The child has since died. The tumor proved to be a rapidly growing sarcoma. He thought that if in young children the tumor appears to be quickly recurrent, and not easily isolated, that no operative interference should be attempted.

Dr. Kipp, of Newark, thought that in many cases these tumors of the orbit are not primary, but secondary, and that the primary tumor may be in such a position as not to attract attention.

Dr. Harlan, of Philadelphia, reported several instances of inflammatory exudations in the orbit simulating tumors, and illustrating the importance of exercising great care in diagnosis.

Dr. W. S. Bennett, of New York, exhibited a series of new test-letters.

Dr. Norris, of Philadelphia, presented a new sheet of metric test-letters, devised by Dr. Oliver, of Philadelphia.

Dr. C. R. Agnew, of New York, made a brief reference to a case of occasional or simulated blindness, in which the vision suddenly returned.

Dr. Theobald described a similar case in which there was sudden blindness. The pupil acted normally, and the ophthalmoscope revealed no disease. A favorable prognosis was given, and the patient recovered in a short time.

Dr. Buller, of Montreal, thought that these cases could not be properly termed entirely imaginary. He thought that there was, for the time being, a functional loss of power in the nerve. He referred to a case in which there was hysterical blindness and deafness, associated with loss of sensation in the skin covering the mastoid region. On one occasion he applied to the anæsthetic surface an iron sufficiently hot to raise a blister. This was done without the patient's knowledge, and unexpectedly. But it did not cause her to wince.

Dr. Roosa had been led to believe from his experience that in these cases there is a basis for the blindness in the ocular condition. There is a derangement of sight from some condition, and the patient finally imagines that she is blind.

Dr. Harlan, of Philadelphia, considered that there were two classes, one in which there is purely deception, perhaps the result of deranged mental condition, and the second in which there is a real temporary suspension of function.

Dr. Risley, of Philadelphia, thought that some of these cases might be explained by an enfeebled condition of the circulation, in which the heart was unable to force the blood against the normal intraocular tension, and the loss of vision thus result from want of nourishment of the retina.

Other cases of hysterical blindness were described by Dr. Williams, of Cincinnati, and Dr. Andrews, of New York.

Dr. E. E. Holt, of Portland, Me., read a paper on

SOME OF THE RESULTS OBTAINED IN THE COMPILATION OF ONE THOUSAND CASES OF REFRACTION.

The writer had been in the habit of recording all the measurements connected with the prescribing of glasses. As a result he had found in one thousand cases thus recorded the average distance between the centres of the pupils of the human eye to be about sixty millimetres, The average of other measurements were given, and the importance of the physician determining and designating them and then seeing that they were carried out was dwelt upon.

A paper on

RAPIDLY PROGRESSIVE MYOPIA CHECKED BY SECTION OF THE EXTERNAL RECTUS,

was read by Dr. G. C. Harlan, of Philadelphia.

The case was that of a boy, aged sixteen, in whom myopia was progressing rapidly. The external rectus was divided seven years ago. The internal rectus was also exercised by the use of prisms. Since then there has been no increase of the myopia.

A paper was read by Dr. Samuel Theobald, of Baltimore, on

THREE CASES OF PROGRESSIVE ASTIGMATISM.

Astigmatism of traumatic origin, the author remarked, is observed not infrequently to undergo changes in de-

gree, but it has been commonly held that congenital astigmatism does not alter in degree though the refraction of the eye as a whole may undergo marked change. The cases which he reported he thought proved that there were some exceptions to this rule. The first case was that of a young man who, with a high grade of hypermetropia, had an astigmatism of each eye which required for correction, a $+\frac{1}{20}$. The case was observed at intervals during a period of twelve years, and during that time the astigmatism increased until finally a $+\frac{1}{13}$ c. was needed to correct it.

The second case was one of compound myopic astigmatism in a young man in which there occurred along with an increase of the myopia a growth of the astigmatism, during a period of sixteen years from $\frac{1}{16}$ to $\frac{1}{8}$.

In the third case a simple myopic astigmatism in a physician aged twety-five years, requiring a $\frac{1}{24}$ c. in one eye and a $\frac{1}{30}$ c. in the other for its correction, changed in five years so that a $\frac{1}{11}$ c. and a $\frac{1}{13}$ c. respectively were needed.

The speaker regretted that the examinations had not all been conducted under a mydriatic, as they would then be more apt to carry conviction to the minds of those disposed to be sceptical regarding the progression of astigmatism. He did not believe that the result would have been different. Such cases are not frequent, but it is important that the fact should be recognized. As the increase of astigmatism is probably due to change in the corneal curvature, the phenomenon should be met with more frequently in the yielding myopic than in the relatively stable hypermetropic eye.

(To be Continued.)

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

DISCUSSION ON THE PATHOLOGY OF REFLEX OPHTHALMITIS—THE NEW GOVERNMENT AND MEDICAL MATTERS—DISCUSSION AT THE OBSTETRICAL SOCIETY ON THE USE OF ANTISEPTICS IN MIDWIFERY PRACTICE—ARCHITECTS AND SANITATION.

LONDON, July 18, 1885.

An important discussion on the pathology of reflex ophthalmitis took place at the last meeting of the Ophthalmological Society. The discussion was based upon a paper on the subject read by Mr. Hutchinson, F.R.S, at a previous meeting. Mr. Hutchinson propounded the theory that reflex ophthalmitis had nothing to do with the nervous system. He thought the circulatory fluids rather than the nerves were the means by which the secondary lesions were originated. He suggested that certain elements derived from the original seat of disease were absorbed into the circulation, but that these elements only produced lesions in those tissues which were practically similar to the tissues in which the original lesion existed. He considered it a case of selective affinity. The elements were first given off from the ocular inflammation and circulated in the blood, and then picked out precisely similar tissues in the other eye as the seat of their selective inflammatory action. Mr. Hutchinson aptly remarked that it was an example of emigration in which the emigrant, cast off from home, settled down in a part where there were similar conditions to those he had left. Mr. Hutchinson maintained that such a theory as this would explain the very exact symmetry of reflex ophthalmitis and other related conditions. He said it would hold good, not only for traumatic diseases, but for other forms of acute inflammation, such as pneumonia. Mr. Hutchinson proceeded to develop this theory at some length. In discussing it, he remarked that a similar, though not identical theory, had been put forward in 1880, by Berlin, though he (Mr. Hutchinson) had only become acquainted with it after his own theory had been formed.

Mr. Henry Power opened the discussion on Mr. Hutchinson's paper. He said Mr. Hutchinson's theory presented many difficulties. How could it explain the frequency and rapid character of sympathetic ophthalmitis in young children as compared with adults? also its frequent occurrence after wounds of the ciliary region? How were we also to explain the long intervals which sometimes elapsed before it came on? In many cases, too, the diseased eye caused irritation, but not complete sympathetic ophthalmia. Relapses were also difficult to explain on this theory. Mr. Power's opinion was that some irritation was propagated from the damaged eye to the sympathizing one, either along the vaso-motor, ciliary, or optic nerves.

Mr. Spencer Watson objected to Mr. Hutchinson's theory on the ground that the eyes were the only organs of special sense subject to sympathetic inflammation. He admitted, however, that the appearance of gouty inflammation in joints symmetrically situated favored the theory. Mr. Watson believed that in sympathetic ophthalmitis the inflammation extended by continuity of tissue along the lymph-channels of the optic nerve.

Dr. Noyes, of New York, then spoke. He said we were not yet in a position to controvert any theory, and he was not prepared to support one. The doctrine of propagation by bacilli was well deserving of consideration. We wanted more facts concerning the circumstances under which sympathetic ophthalmitis occurred and did not occur. There were many classes of cases. In some we had to do with mere neurotic irritation, while in others there was genuine inflammatory exudation. Some of the latter sort might be explained on the assumption that the primary inflammation had taken on a septic character. Sometimes the wearing of an artificial eye was followed by the development of sympathetic inflammation which was not a true sympathetic ophthalmitis. He had seen herpes zoster ophthalmaticus followed by sympathetic inflammation of the other eye. Dr. Noyes said he had often seen cases of damage to the ciliary region which were not followed by sympathetic inflammation. He had known penetration of the globe by foreign bodies to be totally harmless. A case was mentioned of nineteen years' standing in which a foreign body in the iris had caused merely local trouble. Cases of foreign bodies in the vitreous were referred to, and also one in which a percussion-cap remained in the lens without causing any changes for some time. The formation of bony shells in damaged and atrophied globes might be followed by neurotic irritation of the other eye. Some cases of partial shrinking of the globe, caused by sympathetic irritation, might be recovered from. A shrunken, sensitive stump might not cause reflex irritation. He thought such cases tended to dispose of the theory of propagation by the ciliary nerves. Again, cicatricial tissue might or might not lead to changes in the other eye. In some cases he had found that mere removal of the cicatrix or other local mischief led to improvement in the sympathizing eye. The facts were so varied, numerous, and contradictory, that he did not know how to make them fit in with any one theory. Dr. Noyes referred in conclusion to the excellent results which sometimes followed the sub-conjunctival or sub-scleral division of the ciliary nerves. His experience during twenty-five years led him to think that indiscriminate enucleation of diseased globes was a practice of doubtful value. Of late years he had not largely recommended enucleation, and believed that he had thereby saved many useful lives.

Dr. Mules said he thought that sympathetic irritation and inflammation, though they had something in common, ought to be separated. He suggested that the former dilated the lymph-spaces, and so allowed infective elements to pass more easily. The length of time which sometimes elapsed might be explained on the bacterial hypothesis. He was not prepared to say that bacterial elements might not arise in the body without a perforating wound.

Dr. Brailey remarked that Dr. Mules's hypothesis was wide and comprehensive. Criticising Mr. Hutchinson's views, he said it was not necessary to advance another hypothesis; it was sufficient to show that that one did not hold good. How were we, he said, to explain on it the fact that secondary sarcoma was so rare in the other eye? In sarcoma of the eye the commonest site for the secondary growth was in the liver. Again, suppurative panophthalmitis was more likely to be followed by purulent meningitis than by a similar suppurative disease of the other eye; so that we had instances in which cancerous or pus cells were taken up into the circulation and caused similar disease in other tissues rather than in the other eye. Dr. Brailey said he did not support any doctrine, but he thought the facts were more explicable on the theory of direct transmission.

Mr. Nettleship said that the theory of blood-infection accounted more easily for some of the phenomena of the disease, viz., the simultaneous appearance of changes, such as neuro-retinitis or iritis, in widely different parts of the eyeball. The difficulties in accepting the theory were, that with it it was hard to understand how the incubatory period could ever be so long as it sometimes was, or why it should break out in the sympathizing eye at a long interval after the removal of the infecting eye. Two other questions might be asked, which would perhaps tell as much against the theory as for it. How could cases be explained in which parts outside the eye underwent organic change in the course of sympathetic inflammation? And how was it that the exciting eye might be but slightly damaged, though the sympathizing eye suffered profoundly? The severity of the inflammation in the latter must depend upon the number of germs it contained; if these were bred in the exciting eye, why did it not suffer in proportion? On the other hand, if they were not simply carried by the blood but multiplied in it, how did the other tissues of the body escape serious change? As regarded the transmission theory, there were difficulties in regard to all the paths along which the disease had been thought to travel. Deutschmann's view that septic inflammation was conducted along the optic nerves met with a certain amount of support from clinical facts. Mr. Nettleship concluded by stating that the chief objection to the theory of transmission along the filaments of the fifth or sympathetic nerves was that the path would be so very long and narrow; the nerve-twigs were so difficult to examine that inflammatory changes in them might escape detection.

In replying, Mr. Hutchinson said he perceived nothing in the arguments which had been brought forward which led him to doubt that his hypothesis might not still be the correct one. It was merely tentative. He said that Mr. Power seemed to hold two theories, one of reflex irritation, and another of direct extension of inflammation. He himself had no doubt of the occurrence of reflex irritation, and the fifth nerve was the agency in this process. According to some, it was dangerous to excise the exciting eye for fear of increasing the irritation; this was not, however, his view. With regard to the length and irregularity of the intervals, and the relapses of sympathetic ophthalmitis, he did not think such facts were more difficult to explain on his than on any other theory. Symmetrical cancer and sarcoma, also, though rare, were not unknown; cases of secondary tumor of the eye had been shown at the Society that evening and at recent meetings. Moreover, the sequence of the development of secondary growths varied exceedingly, and there was a general law to that effect.

The change of government is not without its effects on medical interests. There is now not the slightest chance of the Medical Bill being brought forward, and as the new Parliament will be busied with weightier matters, it may be regarded as practically shelved for some years at least. The Lunacy Acts Amendment Bill has been withdrawn, to the great relief, doubtless, of the owners of private asylums. The Poisons Act introduced by the late government has also been abandoned, but in future the stamps on patent medicines are to be altered so as to remove all appearance of a government guarantee. The new stamps are to bear the words, "This stamp implies no government guarantee." The question of disqualification for medical relief has assumed a new phase. Greatly to the surprise of every one, the new Conservative Government have taken up the matter and have introduced a bill to remove the disqualification. The bill is very similar to that brought forward by an independent Radical member while the late government was in office. I have previously referred to the opinion of the profession on this subject, and will only add that there seems to be some justice in the opinion freely expressed by many, viz., that the introduction of the present measure is simply a bid for the votes of the new electorate.

At a recent meeting of the Obstetrical Society the question of antiseptics in obstetric practice was discussed at some length. The subject was introduced by Dr. Priestley, who gave an account of a visit he had paid to some maternity hospitals at Copenhagen, Helsingfors, and St. Petersburg, and the antiseptic measures used therein. These had resulted in a considerable reduction of mortality. In the ensuing discussion Dr. Matthews Duncan remarked that the subject of antiseptics was the greatest in the obstetric department, but it got very little attention. It was more important than the prevention of epidemics, for they only came occasionally, while puerperal deaths continually occurred. In the history of the subject all measures had failed to reduce mortality till antiseptics were introduced.

Dr. John Williams said that while it was not possible to abolish by antiseptics the effects of pregnancy and labor, we might hope to do away with deaths from puerperal fever. Taking the deaths in childbed at one per cent., the lowest mortality after the destruction of puerperal fever would be a quarter per cent. The object should be to reduce the mortality to this level, and he believed it might be attained by antiseptics. This was the object of Dr. Champneys and himself at the General Lying-in Hospital, but it had not been attained. They had used in succession carbolic acid, permanganate of potash, and corrosive sublimate as antiseptic agents. The last had been in use since May, 1884. Since it had been employed there had been no deaths from puerperal fever and scarcely any morbility. Dr. Champneys said the total mortality at the hospital during the last four years and a half was 0.66 per cent. The last two deaths were from phthisis, with which the patients were practically moribund on admission. Dr. Playfair, Dr. Braxton Hicks, Dr. Harvey, of Calcutta, and others also spoke.

All the speakers agreed that the use of antiseptics was of great value in obstetric practice. Several of the speakers referred to the paramount importance of antiseptic cleanliness of the hands, including the nails, and this as much on the part of the nurses as on the part of the medical men.

At the anniversary dinner of The Sanitary Institute of Great Britain a rather sharp passage of arms took place between the Right Hon. G. Sclater-Boothe and Mr. Ewan Christian, President of the Institute of British Architects. The former roundly accused architects of gross ignorance in sanitary matters, and maintained that the medical profession had been the pioneers in sanitary reform. The latter defended the architects and laid the blame on the Metropolitan Board of Works, who had, he said, allowed whole estates around London to be covered with houses which were "mere rubbish," and a disgrace to the metropolis. He said the Board of Works ought to acquire new Parliamentary powers to check this building of unsanitary districts and to provide a proper proportion of open spaces, after the example of Chicago, which had reserved seven parks and thirty miles of boulevards.

THE OPERATIVE TREATMENT OF INTESTINAL OBSTRUCTION.[1]

By FREDERICK TREVES, F.R.C.S.,

HUNTERIAN PROFESSOR AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON TO, AND LECTURER ON ANATOMY AT, THE LONDON HOSPITAL.

In the history of the science of surgery it is not difficult to find instances where the progress of surgical therapeutics has been hampered by a nomenclature; and were such instances not forthcoming the present subject would, at least, afford an excellent example. By conventional usage intestinal obstruction is spoken of as if it were a clearly differentiated ailment, possessed of unvarying characters and a precise individuality. It is in reality a generic term, and one that embraces many conditions. At the most, it expresses a prevailing feature common to many different anatomical states. It is the product of clinical and not of pathological knowledge. It is the surviving relic of the old term "ileus," a term that was applied to a certain combination of symptoms at a time when the anatomical basis of those symptoms was without form and void. It is now known that the "ileus" of the ancients may depend upon a great variety of anatomical causes, separated from one another in many instances by the most diverse characters. Operative surgery obviously can concern itself solely with anatomical data. A symptom is beyond the reach of the surgeon's knife. I venture to think, therefore, that any discussion as to the operative treatment of intestinal obstruction must be founded upon our pathological knowledge of the disease, and must start from that standpoint. "Intestinal obstruction" is hardly a translatable term. It has different meanings to different minds. It is impossible to discuss under one heading the treatment of a collection of symptoms that, although alike, may depend upon such different conditions as a fibrous structure of the bowel on the one hand, and an impacted calculus on the other. It would be as reasonable to consider retention of urine as a distinct and isolated malady without recognizing that it may depend upon a stricture of the urethra in one case and an impacted calculus in another.

The operative treatment of intestinal obstruction is most conveniently considered under three heads. 1, The treatment of acute obstruction; 2, the treatment of chronic obstruction; and 3, the treatment of chronic cases that have become acute. Time will not permit a full consideration of the subject, and I think it would be better, therefore, in the present instance to deal solely with one phase of the affection, and to limit the discussion to the acute form, since it presents the most urgent claims to the surgeon's attention.

Acute Obstruction.—The fairly defined collection of symptoms that make up the condition clinically known as acute obstruction may, for our present purpose, be ascribed to three anatomical conditions: 1, To the hernia-like strangulation of the bowel; 2, to volvulus of the sigmoid flexture; and 3, to acute invagination.

1. Under the former heading many structural causes of obstruction may be placed. The following are the most common: Strangulation by peritoneal bands of all kinds, strangulation by omental ligaments or cords, strangulation by Meckel's diverticulum or by an adherent appendix or Fallopian tube, and lastly, strangulation through slits and apertures. With the last-named would be included internal herniæ. In their precise anatomy these various forms may be, and indeed are, often very unlike one another. The lack of resemblance, however, is no more pronounced than is the difference between an adherent appendix and an adherent diverticulum, or between these structures and a cord-like adhesion or an omental band. In every instance a knuckle or loop of bowel is held and kept in bondage until it is strangulated. The mechanism of the obstruction is in all main points identical with that of strangulated external hernia, the general pathology is the same, and, with some minor modifications, the symptoms are the same. For these reasons I have ventured to class all these forms of occlusion under the one heading of "hernia-like strangulation of the bowel." I do not know by what means the condition of the intestine in these cases could be distinguished from that met with in strangulated hernia, and it is also well to note that the segment of the intestinal canal that is usually involved in rupture is identical with that that is most frequently implicated in the internal form of occlusion. The varieties of intestinal obstruction that are classed under the above general heading are comparatively common, and, indeed, they form together no less than one-fourth of all known varieties of intestinal occlusion, both acute and chronic.

The *treatment* I would venture to propose is the following: The patient should be placed in bed and kept absolutely at rest. Some relief to the abdominal pain may be given by warm applications to the belly. The primary object in the general management of the patient should be to secure complete physiological rest to the alimentary canal. Physiological activity means increased peristalsis; increased pain, vomiting, and collapse; increased engorgement of the bowel, and an aggravation of the condition of the damaged part. No food of any kind should be administered. The dryness of the mouth and the intense thirst may be relieved by sucking ice, or in instances where this is not well borne, by sipping hot tea. Perfect rest may be brought to the disturbed intestine by means of opium. Some surgeons prefer belladonna, but it appears to me that a hypodermatic injection of morphia acts with greater readiness and certainty, and brings about a more complete paralysis of the gut.

It must be borne in mind, however, that by the use of opium the symptoms are masked, and the administration of that drug should be directed cautiously before the diagnosis has been established. It is as well to have the colon emptied, when occupied by fæces, by means of an enema, and, when once the bowel is stilled by opium, thirst may be relieved by copious enemata of lukewarm water without producing increased intestinal disturbance. So far for the preliminary routine treatment. The next step should be an attempt at the relief of the obstruction by laparotomy.

I would venture to urge that laparotomy should be performed, when possible, within the first twenty-four hours; provided, of course, that the diagnosis is in its main point clear. The arguments that may be urged in favor of an early interference are these: The course of the malady is rapid. Its average duration is six days. Its termination is fatal. The final issue appears to depend not so much upon the age and state of the patient, or the immediate cause of the obstruction, as upon the amount of bowel involved and the rigor of the strangula-

[1] Read before the British Medical Association, Cardiff, Wales, July, 1885.

tion. It is to the speedy relief of the dying intestine that all the surgeon's attention should be directed. With regard to the question of spontaneous cure, it is certainly not impossible; but I have been unable to find any recorded case or any museum specimen that affords an instance of it. Patients who have died of acute obstruction of the kind now under discussion have had previous attacks of acute occlusion in no way differing, except in duration and mode of ending, from the final fatal attack. It would be fair to assume—and it is only an assumption—that the previous attacks were of the same pathological character as the final one, but that they ended in spontaneous cure. Certain specimens also point to the possibility of relief by means of gangrene of the obstructing band or diverticulum, and also by the formation of a protected perforation with the subsequent development of an artificial anus. It must be evident, however, that these meagre data form no excuse for delay. Laparotomy is in itself not a serious undertaking. Its high mortality in the present class of cases depends, I venture to believe, upon the fact that the operation is usually undertaken too late. It is regarded as a last resource, whereas it should be the first resource, since it is the only resource. When once the diagnosis of a strangulated hernia has been established, and taxis has failed, no surgeon, I imagine, is disposed to temporize. The condition of the bowel in these cases is identical with that found in strangulated rupture, and the therapeutic principles that apply to the one should apply to the other. It seems to be tampering with life to waste time over the administration of metallic mercury and enemata of tobacco and the like. To thrust an aspirator into the abdomen, as some advise, is a stab in the dark, an empirical proceeding that leaves everything to chance. Massage or abdominal taxis has its advocates, but the procedure is at the best a blind one. The manipulation of the abdomen may, by a rare combination of circumstances, reduce a snared loop, but it is as likely to aggravate its condition and to produce a perforation in a segment of intestine that is approaching gangrene and that needs the tenderest handling. Even if the diagnosis be ill founded, the laparotomy merely resolves itself into an exploratory incision. Such incision adds but a fractional part to the sum-total of the risk to life involved; it displays a course of action, and even if it be found to be of no avail it is questionable whether in many cases it hastens the inevitable ending. The use of laparotomy in other than acute intestinal diseases for purely diagnostic purposes has been clearly established, and has been accredited a position of considerable and undoubted value.

With regard to the technique of the operation, I take it that the incision should be made in the linea alba, below the umbilicus; that it should be large enough to admit the entire hand at once, and that it should be made under antiseptic precautions. With regard to the latter point, it does appear to me—speaking only from my own experience—that much of the success of these operations depends upon the observance of the strictest Listerian methods, including the use of spray throughout the whole of the operation. It is well also that the incision should be a clean cut, and that the use of that uncouth weapon, the steel director, should be discarded. When the abdomen has been opened, the carbolized hand should be cautiously introduced, any protrusion of intestine being prevented by means of a flat warm sponge. The hand should be directed toward the cæcum; and if that part of the colon be found empty and flaccid, it may be assumed that the obstruction is in the small intestine. It is well next to search for the seat of trouble in the right iliac region, about which it is most commonly placed. If the affected loop be not readily discovered, I would strongly advocate Mr. Halke's plan of feeling for the collapsed coils below the obstruction. These coils are most commonly hanging in the pelvis, and by passing them through the fingers the constriction may be reached without much loss of time. It is needless to point out the difficulty of finding the point required by simply passing the small intestine in review inch by inch. Such a procedure is as likely to direct the surgeon's fingers to the pylorus as to the obstructed loop. The method also of straightening the mesentery, so as to make out its right and left side, is of much value in preventing the error just named. I think that the practice of allowing the intestinal loops to protrude, and of then examining them in detail, is open to serious objections, apart from the fact of its being quite unnecessary. The procedure is, however, advocated by some surgeons of considerable note. I am in the habit, as soon as the abdomen is opened, of placing a large, warm, carbolized sponge deep in the pelvic cavity. It is removed just before the operation is completed, and its use certainly economizes time, and saves much manipulation of the pelvic viscera and intestines by sponging. Should the bowels protrude and any difficulty exist in their proper reduction, I would point out that the puncture of the engorged intestines above the obstruction, for the purpose of relieving distention, is by no means either a simple, or a harmless, or even a useful addition to the operation. The closure of these punctures in instances where the bowel is much distended, paralyzed, and hyperæmic is, I venture to think, often not so certain as is sometimes supposed. When the obstruction has been found, small bands may be torn across, while larger ones may be divided between two catgut ligatures. An appendix or a diverticulum should be excised close to its base, and the opening so made closed by Lembert's suture in such a manner as to bring the serous surfaces in contact. Any persisting slit or aperture may be closed by a few points of catgut, so as to prevent any further trouble at the same spot. The involved bowel, if in good condition—that is to say, if still of good color, smooth surface, elastic, and resisting—may be returned free into the abdomen; but if it have lost its elasticity, be of dull surface, or visibly gangrenous, I am of opinion that it should be resected and an artificial anus established. I think that in these cases the immediate suture of the divided bowel after the resection is to be condemned, and that all the recorded cases, so far as at present known, are in favor of the establishment of a temporary artificial anus. In the first place, the suturing of the bowel after the excision would greatly prolong the operation, and the condition of the patients upon whom these operations are performed is usually not such as would encourage prolonged narcosis. In the second place, it is the obstruction to the bowel that clamors for relief, and not the mere circumstance that a segment of intestine is gangrenous. It must be remembered that the bowel above the obstruction is greatly distended, and if the intestine be sutured and returned, that distention will remain but imperfectly relieved. The bowel at the suture line will be entirely paralyzed, and will itself form a cause for an abiding obstruction. In the third place, it is difficult to precisely define the limits of the gangrenous action; and even if those limits are widely trespassed in the resection operation, there is still the circumstance that the state of the bowel above the occlusion is exceedingly unfavorable for the kind of healing process that the operation demands. Lastly, there is the mechanical difficulty of uniting the large and distended tube of bowel above the constriction with the shrunken and collapsed segment that exists below it. On these grounds, I think, therefore, that strong claims may be founded in favor of a delayed union of the parts separated by the excision.

The abdominal wound is closed in the usual way, and unless any peritonitis exists, I take it that no drainage-tube is required. If, however, peritonitis should have been established, and especially if it has led to much effusion, I would suggest that the whole abdominal cavity should be freely washed out with a weak carbolized solution, at a temperature of 98°, and that the peritoneal sac should be drained.

One point remains, and it is not perhaps a very important one. It is usual, with many surgeons at least, to have the abdomen supported, for a considerable period after any operation involving an opening of the belly, by a broad bandage or binder. The object, I take it, of this support is to prevent any yielding of the parietes at the seat of the wound, and to protect the patient from the possibility of some degree of ventral rupture. In stout women with pendulous abdomens this practice may be of value, but in patients of ordinary build its adoption appears to me to be a little against reason. If the abdominal parietes yield when the patient has left her bed and is up and about, such condition may fairly be ascribed to structural weakness of those parietes. It may also not be unfair to assume that if the abdominal walls were to become strengthened, such protrusion would not occur. Now I take it that a musculo-aponeurotic structure like the anterior abdominal wall is only to be strengthened by exercise ; and the use of the bandage not only greatly limits such exercise, but causes the responsibility of supporting the viscera to be thrown upon the fabric, and not upon the abdominal muscles. No man would endeavor to strengthen a weakened arm by holding it in a sling. I have been in the habit, in all cases in which I have opened the abdomen, for any cause, of keeping the patient in the recumbent position for—on the average—three weeks, and then of allowing her to move about without any kind of artificial support to the abdomen. So far I have never seen anything but a dense, firm cicatrix as a result of this practice.

With regard to the prognosis that has been given, as pertaining to the present form of obstruction, it must be noted that certain cases have been recorded where symptoms of an acute character existed, and where a recovery followed after a non-operative mode of treatment. Some of these cases may be examples of spontaneous cure. It would, perhaps, be not unfair to surmise that others may have been the subjects of an imperfect diagnosis, while the remainder may have belonged to certain rare forms of acute strangulation that can hardly be clinically distinguished from the hernia-like obstruction just dealt with. Among these forms may be named strangulation *over* a band, acute kinking of the small intestine, some cases of volvulus of the lesser bowel, and of occlusion by the pressure of an external tumor, or by a foreign substance inside the intestine. These forms are all quite rare, but may all be the subject of spontaneous relief. It will perhaps be allowed, however, that a laparotomy in such cases would not be a serious complication, and would render recovery somewhat more definite and certain.

2. Acute volvulus of the sigmoid flexure. Volvulus of any part of the intestinal canal other than the sigmoid flexure being comparatively rare, and chronic volvulus being still more uncommon, it will be convenient under the heading of volvulus to limit all observations to the acute twisting of the sigmoid flexure. This species of volvulus forms one-fortieth part of all varieties of intestinal obstruction. Its diagnosis is not obscure, and there is indeed little difficulty in differentiating it from all other forms of acute occlusion save that due to the kinking of the loaded sigmoid flexure above some stricture at the commencement of the rectum. So far as I can ascertain, there would appear to be no prospect of spontaneous recovery in these cases when once the twist has become complete. The average duration of life in twenty cases that I collected was six days, and the usual cause of death would appear to be from peritonitis, which is apt to set in somewhat early in the case.

I have pointed out in my Hunterian lectures, at the Royal College of Surgeons, that the arrangement of the normal sigmoid flexure is liable to considerable variation. The condition of the gut that is necessary for the production of a volvulus is the following: The loop must be of considerable length, the meso-colon must be long and narrow, and the two extremities of the sigmoid or omega loop must be brought as close together as possible. It is about this neck of the loop that the twist takes place, and the prognosis does not seem to be affected by the particular direction of the volvulus. The anatomical condition just named may be congenital, or it may be brought about by some contracting peritonitis involving the sigmoid meso-colon, although without doubt the commonest cause of the peculiar arrangement of the loop is chronic constipation. It may be necessary to point out that volvulus is much more frequently met with in males than in females, and that the bulk of the cases fall between the ages of forty and sixty.

The treatment of volvulus of the sigmoid flexure involves many points of serious difficulty. I take it that in the first instance the treatment by rest and starvation would be insisted on as a matter of routine ; opium would be administered, and it may be as well to empty the rectum by an enema. With regard to more active interference I believe that all attempts at relief by means of enemata or rectal tubes are likely to prove not only quite useless, but actually harmful. If the precise relation of the parts be borne in mind it will be perceived that a forcible injection into the rectum will tend to tighten rather than to relax the twist. In one subject, who had died of an unrelieved volvulus I found that when the twist had been nearly reduced on the post-mortem table it could be made to reappear by injecting water into the rectum.

Simple laparotomy, it must be confessed, is not a very promising procedure in these cases. In the first place, the distended coil often reaches to the ribs, or even to the diaphragm, and by no ordinary incision could the great loop be dealt with. Through such an incision, however, a volvulus may be reduced with success, as shown by a case reported by Mr. H. Clark (*Lancet*, 1883). If the abdomen be opened, I would suggest that the gut be reduced in size by a puncture with a capillary trocar, and then that attempts be made to replace the distorted flexure. This procedure may succeed, and it is possible that the surgeon may convince himself that the probability of a return of the volvulus would not be very considerable. In actual practice, however, I anticipate that the trocar will not sufficiently empty the loop to render it easy to be handled, and that after the reduction the operator will have reason to believe that if no further steps are taken a return of the twist will be exceedingly probable.

In any future case, therefore, that may come under my notice, I intend to adopt the following operation : To perform a laparotomy in the middle line, to puncture the gut and attempt its reduction. If this fail, or the result appears unsatisfactory to evacuate the involved gut through an opening in the summit of the flexure, to unfold the volvulus, and establish an artificial anus, using the opening just alluded to for that purpose. By this method the volvulus could be relieved in a very short space of time and without much handling, and the distended colon above the twist could empty itself through the artificial anus. Inasmuch as this artificial opening would be at the summit of the sigmoid flexure, a return of the volvulus would be impossible. The flexure would be permanently retained in good position by means of the adhesions that would form about the fecal fistula. In process of time the artificial anus would be closed by one or other of the operations adopted for that purpose. It may be unnecessary to point out that there is no anatomical difficulty in establishing an artificial anus leading to the sigmoid flexure through the middle line of the abdomen. The operation just alluded to is little more than a simple colotomy, since the manipulation of the bowel antecedent to the opening of the colon need not be prolonged. One thing is certain, that these cases of acute obstruction demand very prompt treatment. The rapidity with which peritonitis sets in in the present form of occlusion is very striking, and there is, moreover, great risk of the involved loop passing into a state of gangrene. A left lumbar colotomy in these

examples of volvulus would certainly relieve the obstruction, but it would probably effect no change in the volvulus, and there would be great likelihood that the artificial anus established would have to be a permanent one.

3. Acute intussusception. The chief point of interest in connection with this form of obstruction is concerned in the question of the frequency of spontaneous relief, and the matter that presents itself most prominently to the surgeon's notice relates to the reliance that is to be placed upon the prospect of such relief. This form of obstruction is quite common, and forms, indeed, no less than one-third of all known varieties of the affection, excluding hernia and obstructions due to congenital defects. The acute cases are defined as those that—if they follow an uninterrupted course—end in death within seven days. These cases form about fifty per cent. of the whole number of invagination cases. It is well, also, to bear in mind that the enteric and ileo-colic forms are not usually acute, and that fifty per cent. of all the examples of the disease are met with in patients under ten years of age. Spontaneous cure may be met with under two circumstances. In the first place, the invagination may reduce itself before the period has been reached when from structural changes it has become irreducible; and secondly, spontaneous cure may occur after the invagination has become irreducible, either by the formation of fecal fistula above the obstruction—a form of relief that is very rare—or by the elimination of the gangrenous intussusception.

The method of relief named in the first category is certainly not infrequent. Most surgeons must have met with instances of acute invagination that have become cured without elimination of the intussusception, and with no more elaborate treatment than that comprised by rest, starvation, and the use of opium or belladonna. It is to be regretted that statistics are not forthcoming to show with what frequency this termination of the case may be expected. To enter at once into the treatment of acute invagination, I imagine that general approval will sanction the immediate use of opium or belladonna, together with practical starvation and perfect rest.

By these measures the peristaltic movements are stilled, the irregular muscular action in the bowel that has provoked the malady is arrested, and the prospect of spontaneous reduction is greatly favored. Presuming that no benefit attends this mode of treatment at the end of twelve hours, it will be expedient to attempt reduction by means of insufflation or forcible enemata. Considerable success has attended these measures. By far the best instrument for the purpose—no matter whether water or air is used—is the admirable insufflator invented by Mr. Lund. I think that in children under ten years of age the injection should be cautiously administered while the child is under the influence of an anæsthetic; but in patients above that age it is, perhaps, safer to carry out this treatment without chloroform. There is no doubt that in adults the best guide to the amount of force to be used is the patient's own sensation. In any instance the colon should be distended gradually. When the bowel is fully distended the air or water should be retained for at least twenty minutes. The injection may be accompanied by gentle kneading of the intussusception tumor, when such exists. I think that it is a matter of primary importance that the bowel should have been rendered quite still by means of opium or belladonna before the attempt at reduction by injection is commenced.

I cannot understand upon what mechanical principles the inversion or shaking of the patient is recommended in these cases. Before such a method were adopted the exact position and extent of the invagination would have to be most accurately diagnosed.

It is obvious that these measures will have no effect when once the invagination has become irreducible. It is to be regretted that at present little is known of the precise circumstances under which such irreducibility takes place. It is known that the invagination may become fixed within a few hours of its formation, and it is needless to remark that adhesions play comparatively a small part in causing an *acute* invagination to become irreducible. Should the measures so far advocated fail after a patient trial, I would strongly urge that a laparotomy be at once performed. If enemata fail early in the case, they are not likely to succeed at a later period, and every hour that elapses renders the prospect of gangrene more immediate.

Against laparotomy in these cases many objections have been urged. In the first place, it is pointed out that an acute attack may become a chronic one. This is true, but the occurrence is very rare. By far the greater number of the patients do not live long enough to enter upon the chronic stage. Moreover, chronic invagination is exceedingly fatal, and out of fifty-nine recorded cases, taken without any selection, I find that there were no less than fifty-one deaths. A far more important objection, however, depends upon the frequent occurrence of spontaneous cure at a period when the patient is *in extremis* and the case desperate. Temporizing is constantly being urged upon this ground. One case of spontaneous cure is an argument against a score of proposed operations. An examination of the matter shows that little dependence is to be placed upon this mode of ending. "Elimination of the gut by gangrene occurs in about forty-two per cent. of all cases; but when it has occurred it by no means follows that the patient recovers. In fact, no less than forty per cent. of the subjects of spontaneous elimination die of the immediate results of the process of separation. Moreover, during the first year of life spontaneous elimination occurs in only two per cent. of the cases, and between the ages of two and five in only six per cent.; and when it is remembered that more than fifty per cent. of the total number of examples of intussusception occur in children under ten, it will be seen that elimination by gangrene offers no very extensive prospects of spontaneous relief. It is true that the older the patient the more chance has he of recovery by this means; but it unfortunately happens that the older the patient the higher is the mortality after the occurrence of the elimination, so that the chance of cure becomes remarkably slight" ("Intestinal Obstruction"). In favor of the operation it must be pointed out that the affection is very acute, that the general mortality of the disease is seventy per cent., and that eighty per cent. of the patients die before the seventh day. I would venture to urge that in these acute cases laparotomy should be performed at least within the first forty-eight hours, and if possible within the first twenty-four hours, provided, of course, that all other measures have failed.

When the abdomen has been opened, the invagination should be reduced if possible. The reduction is best effected by squeezing the intussusception with one hand, while gentle traction is brought to bear upon the gut entering the invagination with the other. Should the mass be found to be irreducible or in a condition that threatens gangrene, the whole of the involved bowel should be resected and a temporary artificial anus established.

It appears to me that there is little to recommend the operation of enterotomy for this class of cases. This measure is certainly readily performed, but it is of the nature of a cut in the dark. It will relieve the obstructive symptoms, it is true; but it will leave the invagination untouched, and leave it possibly to pass on into a state of gangrene or a condition that may lead to diffuse peritonitis.

Antipyrine in Rheumatism.—Dr. Immermann has found antipyrine a most efficient remedy in acute and marked articular rheumatism. He states that it not only reduces the temperature, but also exerts a specific action on the joint manifestations. In one case of marked rheumatism of the trifacial nerve a permanent cure followed the exhibition of only one drachm of the remedy.

PRESBYKOUSIS.[1]

By D. B. ST. JOHN ROOSA, M.D., LL.D.,

PROFESSOR OF DISEASES OF THE EYE AND EAR, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

A certain degree of impairment or diminution of hearing power is, I think, inevitably an accompaniment of old age, or even of life after fifty years. This impairment or loss cannot usually be detected unless certain tests are employed, hence it is usually not noticed in ordinary intercourse. It is produced by a physiological or senile, rather than a pathological, change in the ear, and it is for this reason fairly analogous to presbyopia, and may be termed presbykousis.[2]

Presbykousis may be readily distinguished from the impairment of hearing resulting from chronic catarrhal or proliferous processes in the tympanum and Eustachian tube. By means of the tuning-fork (C^2) and watch, or acoumeter, we may make certain tests, more or less objective, which will make this differential diagnosis between these affections and the impairment of hearing arising from the inevitable changes belonging to advancing years. If a "C^2" tuning-fork be held while vibrating in front of the external meatus and then upon the mastoid process, presbykousic patients always, if they have no disease of the middle ear, hear louder and longer through the air than through the bone. If they do not, a morbid condition of the middle ear, a pathological change, is added to the senile changes. The tick of a watch or of the acoumeter is heard by presbykousic subjects relatively much worse than the human voice. Besides the evidences from these two tests, presbykousis is marked by the fact, that its subjects are more sensible themselves of the impairment of which they complain, than are those about them. In other words, although there is an actual loss of hearing, it does not appear in the ordinary social and business intercourse of life. The fact that the conduction of sound to the ear through the bones of the head, notably of the mastoid process, is lessened as years go on, has been observed, but no attempt has been hitherto made to give this fact any particular significance in relation to the hearing power, nor has it been noted that the symptom exists in old persons in connection with others—the others which I have just described.

It will also be found that persons who are presbykousic, like young persons with good hearing power, hear much better in a quiet place. Indeed, if the circumstances be favorable, if the room be quiet and the distance from the speaker be not too great, then patients not only hear well, but perfectly well. An octogenarian in excellent general health, who consulted me a few mornings since in regard to his sight and hearing, exclaimed, as we sat conversing in an ordinary conversational tone: "Why, I hear you as well as I ever heard any one in my life." And yet this gentleman, a lawyer, said that his hearing was not sharp. On inquiry, I found that he could hear the judge when the court-room was quiet; that he also could hear his clients in his consulting-room; that no one spoke to him of not hearing well; that he was chiefly troubled in noisy places, such as a railway train or a large and vivacious dinner-party, or when the voices or other sounds came from a great distance. This inability to hear at long range is not marked, for the presbykousic patients that I have tested, if free from any inflammatory trouble of the middle ear, can hear an ordinary voice addressed to them in a quiet room, when in a listening attitude, at least fifty feet.

How much worse is the condition of a person, young or old, who suffers from a chronic catarrh of the Eustachian tubes and tympana! He hears badly under all the conditions of ordinary human intercourse. It is only in a din that his hearing power becomes acute enough to enable him to follow and join in ordinary conversation, although carried on very near him, no matter how distinct the tones of the speaker, nor how quiet the room. He thus finds himself unable to carry on any ordinary business, or hear a lecture, a play, or a sermon. His usefulness in any such profession as law or medicine is greatly impaired, if not destroyed. The presbykousic patient, on the other hand, may be greatly annoyed by the subjective loss of which he is so conscious, and which he usually and correctly attributes to senile decay; but he may so arrange matters—not as he does to relieve his presbyopia, by glasses—so as to go on with the ordinary work of life.

The anatomical conditions which form the basis of presbykousis, in the absence of *post-mortem* examinations of a large number of ears of old persons, cannot, as yet, be positively determined. The evidence of the tuning-fork points toward a lessening of the perceptive power of the acoustic nerve. Indeed, the symptoms are characteristic of those generally considered as evidences of a lesion of the nerve. It is possible that there are more factors than one involved in the causation of presbykousis, as there are in presbyopia. Besides the changes in the nerve, there may be, as suggested by Orne Green,[1] a senile dryness and rigidity in all the tympanic structures, a want of vacillancy, which prevents a normal vibration of the drum-head, and a proper conduction of sound to the senile nerve.[2]

It is not probable that presbykousis is caused by abnormal pressure through the base of the stapes bone upon the vestibule and semicircular canals, for vertigo does not attend it.

[1] Read before the American Otological Society, July, 1885.

[2] From πρεσβυς, an old man, and ἀκούω, I hear. Presbykousis is a more euphonious word than presbyakousis, and I hope etymologists will justify me in dropping the vowel.

RECTAL ABSORPTION CONSIDERED THERAPEUTICALLY AND WITH ESPECIAL REFERENCE TO THE RELIEF OF CONSTIPATION.

By C. M. FENN, M.D.,

SAN DIEGO, CAL.

Hitherto the rectum seems to have been studied from an exclusively pathological standpoint, while its lesions have been relegated chiefly to the domain of surgery. Anatomical authorities have seldom done more than describe it as a portion of the colon, and define its surgical relations. Physiologists also have been silent as to any special or important function that it may possess, aside from defecation, being satisfied to regard it as a division of the large intestine, "the office of which is mainly confined to the separation and discharge of certain excrementitious substances;" or still further ignoring its capabilities, to style it "a reservoir for the fæces as they pass from the colon." More recently O'Beirne, Bodenhamer, and others, have been discussing the existence and purposes of its sphincters, in the endeavor to settle certain anatomical and technical questions which they evidently regard as *sub judice*.

For centuries, it is true, clysters have been employed to improve the complexion, to relieve the lower bowel of a portion of its contents, and as doubtful adjuvants to slowly-acting cathartics. But their action was supposed to be chiefly mechanical. In certain emergencies, also, physicians have resorted to medicated injections and suppositories to mitigate pain in the adjacent organs. Nourishing enemata were recommended by the divine Celsus as early as 50 A.D.; but the reliance upon such methods to sustain life, besides being of comparatively modern origin, is yet attended with doubt as to their efficacy. I am not aware, however, that any writer has yet suggested, or attempted to demonstrate, the probability of any other function pertaining to the rectum than that of defecation.

[1] Discussion: American Otological Society, July 15, 1885.

[2] The term presbykousis cannot be fairly criticised because the conditions causing it are not completely analogous to the changes in the crystalline lens and the ciliary muscle, for presbykousis means simply the hearing of an old person, having nothing to do with its causes, as does presbyopia, the *sight* of an old person.

At times, during the past two years, availing myself of such meagre facilities as are afforded by a private practice, I have been pursuing certain studies and experiments which have convinced me that the entire function of the rectum has not been fully appreciated, if, indeed, understood. That it is not sufficiently appreciated may be fairly inferred from the recent researches of Fubiné, with reference to the power of the lungs to absorb defibrinated blood; of Ziemssen, with subcutaneous injections of human blood; and from such comments thereon as the following, from a leading medical journal:[1] "It would be a great help in therapeutics if the functions of the stomach could be temporarily transferred to the lungs, . . . thereby giving the affected organs a rest."

Reasoning from analogy, then, the relative importance of any organ of the human economy may be predicated if it is a duplicate; if it is composite in construction and character, and especially if it is well provided with those elements of action, nerves, blood-vessels, etc. Furthermore, its lesions bear a striking relation to its functional activity. Now, whether we regard the rectum as a duplicate of the stomach, which it greatly resembles in everything save the ability to elaborate peptones, or consider its highly organized structure (in connection with the fact that defecation can be successfully performed through an artificial anus), the conclusion is legitimate that it is something more than a mere gateway for the passage of fæces.

Anatomically viewed, the rectum is the terminal eight inches of the large intestine, capable of great distention, empty except during defecation, and somewhat abruptly putting off the semblance of the lower bowel, of which it forms a part. It is but little shorter than the stomach, and has all of its muscles except the oblique. In the vascularity of its mucous membrane, as well as in many other respects, to which attention will be called as we proceed, it resembles the small intestine. Contrasted with the colon its longitudinal muscular fibres are no longer so distinctly marked, while the circular fibres, arranged in a thick, uniform layer, combine to form the sphincter; its sacculated appearance is lost, and the tube becomes a cylinder, contracted at each end. The connection between the muscular and mucous coats is much less intimate than that of other portions of the intestine, and in this respect, also, is suggestive of the upper portion of the canal. Still greater differences are presented by the mucous coat or membrane, which, pale and comparatively smooth in the cæcum and colon, now becomes thicker and much more vascular. When contracted the membrane is gathered into folds, called by Morgagni columns of the rectum. It also forms three valvular prominences of crescentic shape, their free surfaces looking upward and inward, which may be likened to the valvulæ conniventes of the small intestine. Like the jejunum, it is paved with columnar epithelium. The villi, which disappear at the termination of the ileum, again make their appearance and are inverted. They are so numerous, also, that the width of the intervening tissue is said to be "only one-sixth of the diameter of the follicle."

From the brief description given above it will have been observed that the structure of the rectum is not only in striking contrast with that of the colon, but that it is also of a composite character, so to speak, resembling the œsophagus, stomach, and portions of the small intestine, besides having peculiar features of its own. It will not be necessary to refer in detail to the number and size of the lymphatic vessels and glands of this region, nor to the extensive and elaborate arrangement of the nerves, which are derived from the cerebro-spinal and sympathetic systems. The evidence would be simply cumulative.

Whatever may be our conclusions with regard to so large a number of nerves and lymphatics as connected with a simple excremental gateway, the immense number of its follicles, and especially its vascular supply, are of still greater interest in this discussion, and point to some function more important than secretion and defecation. Whether the follicles secrete or absorb, for purposes of defecation an artificial anus has been found sufficient. Its arterial pabulum, then, is derived from two large arteries, the superior and middle hemorrhoidal, and three smaller ones, making five in all, whose aggregate volume must quite equal that of the three gastric arteries. Of its three sets of veins, the internal hemorrhoidal is chiefly concerned in the function which we would accord to the rectum, viz., the absorption of alimentary, and especially of medicinal substances. The latter certainly are not involved in the doubtful question of peptones. Having verified, by dissections, Kelsey's very accurate description of these veins, I have less hesitancy in using a few paragraphs from his recent monograph.[1] He says: "When the venous circulation of the rectum proper is in-

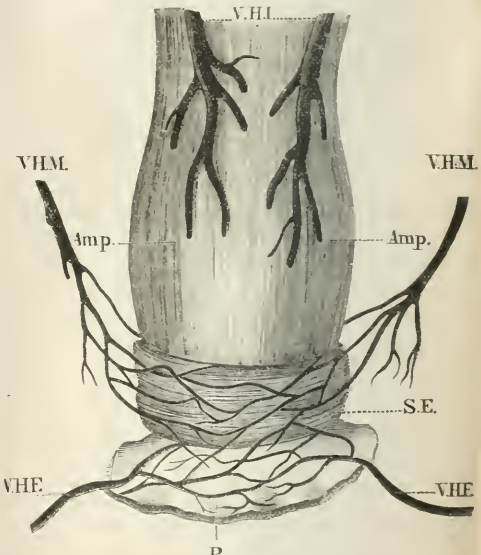

Fig. 1.

jected from the inferior mesenteric vein, three or four large venous trunks may be seen on the external surface of the rectum, ascending on the sides and posteriorly. These veins make their appearance suddenly by five or six branches, which peforate the wall of the bowel about three inches from the margin of the anus. If the rectum be opened longitudinally, and the mucous membrane dissected up to a sufficient height (about four inches), it will be seen that these five or six large veins, already visible on the outside of the bowel, come from within, and that they have already pursued quite a long course under the mucous membrane. They are formed by collateral branches, and especially by about a dozen primitive branches which originate about half an inch above the anus, and ascend in parallel and flexuous lines for several centimetres, to unite into common trunks. (The main trunks referred to, stand out in such bold relief that injection is not required to render them visible. The primitive branches also can be made out clearly by holding the intestine up to the light. From my observations, the accessory branches, or veinlets, are so numerous as to give to the membrane the appearance of a net-veined leaf.) Each of these little ascending branches

[1] New York Medical Record.

[1] Diseases of the Rectum and Anus. (See also woodcut from same work (Fig. 1), showing internal hemorrhoidal vein and ramifications.)

has its origin in a minute pool of blood, the size of which varies in the normal state from that of a grain of wheat to that of a small pea. (In one of my dissections, several of these radicals arose from quite a lacuna of blood near the anus. I did not make out the little pools as clearly as described by K.) These little sacs are arranged in a circular form around the extremity of the rectum. If carefully dissected, they may be seen to be connected with the little veins before mentioned, and also with another little vein which perforates the internal sphincter near its lower edge, and empties into one of the rudimentary branches of the external hemorrhoidal plexus. Many of these little communicating branches between the external and internal hemorrhoidal systems pass through the substance of the external sphincter." It is worthy of remark that, through the hemorrhoidal plexuses, there are anastomoses with the internal iliac veins, by which a direct channel, or communication, is made with the general circulation, while the mesenteric veins which relieve the small intestine, and the large one as far as the descending colon, convey their blood directly to the liver, via the portal vein. May not this in part explain Savory's experiment, showing a more rapid absorption of strychnine per rectum than through the stomach?

Having demonstrated the presence of veins in such large numbers and of such peculiar arrangement, it will only be necessary to refer very briefly to the important function performed by these vessels in other portions of the intestine, and system generally. The intestinal villi, for example, are essentially vascular organs, consisting of epithelial cells covering a network of blood-vessels, while the duct found in each is probably its excretory tube. The occasional presence of fat in the blood, though in small quantity, is a proof of venous absorption, as it could not enter through the lacteals without modification.

Panizza's [1] old, yet interesting, experiments in this line demonstrated that the blood-vessels absorb fluids from the intestinal canal even more rapidly than the lacteals. Küss [2] says that poisonous substances are undoubtedly absorbed by the veins, intoxication taking place so rapidly that the poisons can scarcely be supposed to pass through the lymphatics. Savory's [3] experiment with strychnine, already alluded to, is yet another evidence of this venous function. As a matter of fact, the veins, in contradistinction to the lacteals and lymphatics, may be called the common carriers of the system. This process is repeatedly and well shown in the liver, to which the veins bring materials for the formation of bile, and in certain pathological states diffuse it through the system. The sugar secreted is taken up by the veins and eliminated through the kidneys. "Albumen is transformed, because it comes in contact with the hepatic cells by means of the portal circulation." If these are facts, the question naturally arises, Why may not saccharine and albuminous, in fact, all substances, be taken up by the rectal as well as the portal veins?

Let us now recall a few facts taken at random from comparative and human physiology.

The powerfully digestive function of the lower bowel in solipeds is well established. Again, Bauer [4] has shown that the rectum of the dog can absorb pure albumen, as well as acidulated and saline meats. Liebig [5] found that a solution of salt (one to eighty) was entirely absorbed by the rectum within an hour. A recent investigator,[6] after injecting arsenic into the rectum *post mortem*, found it diffused through the intestine and system.

Upon the supposition that the rectum had neither digestive nor absorptive power, because unable to change colloids into crystalloids, it has been attempted to explain the disappearance of various enemata by *retrostalsis*. A recent contributor to one of our medical journals [7] vouches for the presence of portions of an injection in the small intestine, and for the taste of quinine introduced per rectum. So, too, the "Medical and Surgical History of the War" [8] cites instances of rectal injections reaching the stomach. *Per contra*, Dana's [9] experiments upon sixteen living dogs, seem to establish the fact that fluids, even in large quantity, *seldom* penetrate beyond the ileo-cæcal valve, and hence do not reach the so-called absorbent territory. Professor Dawson,[10] of the Ohio Medical College, in summing up the results of fourteen injections, two of which passed the valve, says, "the experiments performed show that the valve, when intact—when in normal condition—will not allow retrograde passage." Inasmuch as large quantities of fluid and force are required to penetrate the valve, the question does not particularly concern us.

Still further evidence of the existence of this function of the rectum may be drawn from the many cases [11] of rectal alimentation lately placed upon record. Flint writes of a patient whose life was prolonged for fifteen months chiefly by the aid of nutrient enemata. Another case, occurring in a German hospital, was not only kept alive for a considerable period, but gained a pound in weight in one month. C. Kay, Jr.,[12] records, as an evidence of retrostalsis (?), a case of peritoneal tuberculosis kept alive by rectal injections for more than three months. A foreign journal [13] gives an instance of a Roumanian wine-merchant, whose throat was cut by gypsies. By rectal alimentation his life was sustained for two years, until the œsophagus was restored.

I may be pardoned for giving here the details of a case which came under my own observation and treatment about two years ago, especially as it suggested the studies embodied in this paper. It was a typical and protracted case of gastritis, with all the attendant symptoms, such as nausea and retching, burning palms, constipation, low fever, and, of course, great prostration. For more than six weeks there was complete intolerance of solids as well as liquids, even melted ice being regurgitated. Hot-water draughts had not then become so fashionable as at present, though my patient used large quantities of it per rectum. Nourishment was administered only through the same channel. For the constipation, clysters of tepid water, sometimes with the addition of olive oil, were almost daily employed, some of which produced evacuations, while others were absorbed. Her condition was still further complicated from the fact that, believing herself of bilious habit, she had for a long period been tampering with patent and other remedies for the liver, and in the absence of its accustomed stimulant, besides its sympathy with the stomach, this organ now ceased to act. A dose of calomel was given, and after a considerable interval an attempt was made to assist its action by carefully selected adjuvants. But the result was so disastrous that no further appeals were made to the stomach. The exigencies of this case, then, taught me that not only was it possible to sustain life by food administered through the rectum, but that the liver could also be reached through the same avenue.

I need not stop to discuss the question of peptonizing alimentary enemata. As a matter of fact, nitrogenous and albuminous injections have been employed with more or less success for centuries, while the use of peptones as an aid to digestion is of comparatively modern origin. Furthermore, as most medicinal substances are not included in either of these classes, they require no such adjuvants for their assimilation.

I now come to a summary of facts, or "provings," as our homœopathic *confrères* might style them, most of which personal observation and repeated experiment permit me to corroborate. For example, the cathartic effect of aloetic injections has been frequently noted. It

[13] British Medical Journal, 1883.

has often become necessary to suspend their use because of even drastic tendency. "Headland," I believe, says that many remedies are absorbed and eliminated near the same region. Upon that theory, gums, resins, and medicines which do not seem to act until they reach the colon, should be introduced into the rectum. Inunction of the rectum with mercurial ointment will often not only produce loose evacuations, but if employed in sufficient quantity will act as a cholagogue. For certain types of constipation it is often only requisite to anoint the rectum with the unguent the previous evening. If guarded with sufficient opium or belladonna, and repeatedly applied, the specific effect of mercury may be expected; in fact, with more promptness than when rubbed into the skin. In some instances, by rectal medication I have been enabled to cause the expulsion of tæniæ which had resisted the usual methods. In certain cases of gonorrhœa, in which idiosyncrasy of the stomach precludes the continued exhibition of copaiba, cubebs, and oil of sandal-wood, I introduce capsules of the same into the rectum. I believe that the duration of the disease can be materially curtailed by this method, to say nothing of relieving the stomach from such nauseous dosage. Uterine and vesical hemorrhage can be more promptly arrested by administering ergot and other remedies per rectum. A few minims of copaiba, in capsule or emulsion, introduced into the rectum of the child, will ward off many an impending attack of spasmodic croup! In several rheumatic cases, requiring remedies for the relief of constipation, I have employed suppositories of blue mass, colocynth, physostigma, or aloes, as the occasion suggested, with satisfactory results. I have repeatedly noted the disappearance or absorption during a night, of fifteen grains of blue mass, with half as much colocynth. In two cases of paraplegia, a combination of aloes, calabar bean, or cascara sagrada, with or without belladonna and nux vomica, was quite sufficient to regulate the bowels for long periods. Ox-gall in form of suppository, or incorporated with fluid menstrua, not only softens scybala, but not infrequently relieves the constipation arising from a deficiency of the natural secretion. Enemata of hamamelis virginica I regard as almost specific in cases of intestinal hemorrhage, whether of hemorrhoidal or higher origin. Some months since, the writer was summoned in consultation upon a critical case of intestinal obstruction, which had already reached the stage of stercoraceous vomiting, etc. Copious clysters of various kinds having been frequently repeated without accomplishing the desired result, at my suggestion a small injection of olive oil with a few drops of croton oil was employed, and with almost magical effect. Within fifteen minutes the normal peristaltic action seemed to be restored; large doses of castor-oil, as well as nourishment, were retained by the stomach, and convalescence was uninterrupted.

Within a twelvemonth, ether [1] has been successfully administered per rectum, both in Europe and on this continent. Dr. Pepper,[2] of Philadelphia, also reports the successful use of chloroform in the same way. Drs. Vincenzo,[3] Cantani, and others, during the recent epidemic of cholera at Naples, tried injections of tannic acid and opium with excellent results. More recently the panacea, muriate of cocaine, has been employed by injection into rectum and piles,[4] rendering the operation for hemorrhoids a painless one.

But I need not further multiply instances from my own notes, nor from current medical literature. It is evident that, as never before, the profession is directing attention to the possibilities of the rectum as an aid to therapeutics, and the object of this paper is to assure them that their "faith is well founded;" that rectal absorption is no longer a matter of speculation and theory. Furthermore, in my opinion, the time is not far distant when this method of therapeusis will at least supplement, if it does not supplant, most of the means now employed to "regulate the bowels;" the fact that nine tenths of all cases of constipation, acute and chronic, originate in the large intestine, from want of contractile power, irregular peristaltic action, flatulent distention, and deficient moisture, should stimulate us to further investigation and experiment in the direction I have endeavored to indicate. Besides this, the mobile colon, with its gas-harboring flexures, is a most fertile source of the left-side pains, and of many other functional and sympathetic disturbances of thorax and abdomen, which can be soonest dispelled by remedies administered through the rectum. Furthermore, the class of medicines called irritant cathartics, including most of the resins, are absorbed, it should be remembered, with difficulty, if at all. It is manifestly unphilosophical, therefore, as well as hurtful, to pass these through twenty feet of normal intestine, when the colon alone is responsible. An authority [1] upon this subject has written: "Whenever a practicable line of treatment, with little or no medicine, can be successfully adopted in any individual case of constipation, such treatment certainly claims a primary consideration;" meaning, I infer, that the best course is one which interferes least with the general system. In this view of the case, I can suggest nothing better than rectal medication. Yet I would not ignore the hypodermatic use of remedies, a method susceptible of extended application. In my opinion, the administration of medicines should be, and ultimately will be, restricted to these two means. The size of the dose should be diminished, and the interval of administration materially shortened, especially in maladies attended with suffering. When these methods prevail, as I believe they will, the liver and pancreas, so rarely at fault *per se*, will not be called upon to respond to every cathartic combination, and the now much-abused stomach will assert and maintain its prerogative to be the receptacle for food, and food alone.

A few details as to the *modus operandi* may not be out of place at this point. Drugs must be selected, and the quantity modified with reference to the immediate or remote, moderate or full, effect desired. There must also be discrimination as to the doses for different individuals; as for example, the fourth of a grain of belladonna will sometimes seriously disturb vision. The law of endosmosis does not seem to prevail here, whatever may be the fact in other portions of the alimentary canal, the specific gravity of an enema being of less importance than its bulk. Powders may be incorporated with vehicles of varying consistence, of which morphine in water, or dry in capsule, may be taken as a type. In the absence of capsules, syringes, and ointment instruments, one may use blue mass, mercurial ointment, and some of the extracts in mass, though it is better to wet them up with syrup or glycerine. With a little dexterity in manipulation, a bolus or suppository may be introduced into the rectum at bedtime, with fair promise of an evacuation in the morning. For general purposes, the most convenient appliance that has yet come to my notice is a hollow shell, or capsule, of cacao butter, with adjustable cap, manufactured by Hall & Ruckel, of New York. There are several sizes of these, and to fill one of them with powders or extract is the work of a moment. Although drugs seem to be quickly diffused over the absorbent surface by these means, I have thought a long rectal suppository, or bougie, might offer some advantages. Emulsions, if not too bulky, form eligible vehicles for some medicines. If from any cause, such as hemorrhoids, the rectum is irritable or intolerant of medication, it is well to add a portion of belladonna or opium to the dose. Besides this, the former possesses laxative properties, and often may profitably enter into the combinations against constipation. Nux vomica is also a desirable adjuvant where deficient peristaltic action or absence of muscular

[1] Birch on Constipation.

tone is the cause of trouble, its tonic effect seeming to be increased by such immediate application.

In conclusion, we find the rectum to be the antipode of the stomach, as to its position in the alimentary tract, yet presenting many analogies to the latter. It is capacious and, for the most part, empty. As a reservoir, it is superseded by the sigmoid flexure of the colon, and is not indispensable in defecation. Its mucous membrane is thickly inlaid with Lieberkuhn's follicles, or inverted villi, which must be allied in function to those organs in other portions of the intestine, or be superfluous. Besides these, and beneath them, we meet with a congeries of veins and capillaries, or veinlets, which are at least suggestive of the portal vein and its capillaries.

The preponderance of evidence is against retrostalsis, except in rare instances. But admitting the permeability of the ileo-cæcal valve, even under circumstances of great force or quantity, we shall derive no assistance from the lacteals, for the reason that they are especially arranged for the absorption of fat, and are probably only active during digestion. It therefore becomes a question of villi and capillaries at last.

Accumulated facts outweigh all theories with regard to rectal absorption.

Medicinal substances do not require peptones for their digestion and absorption, and, with suitable appliances and in proper combination, may be administered in this way, to the great relief of the stomach and with full assurance of the desired effect.

Clinical Department

THE TREATMENT OF DIPHTHERIA.

Dr. J. W. Alexander, of Newark, O., writes in favor of the constitutional treatment of diphtheria. He thinks that local applications of any sort are of doubtful utility, although, as palliative measures, antiseptic and disinfectant washes are not to be ignored. All caustics and irritants are injurious, he maintains, and should never be used. The following is the formula which he has used with success in many cases: ℞. Chlorate of potassium, 40 grains; simple syrup (slightly warmed) 2½ ounces; dissolve and add aromatic sulphuric acid and tincture of chloride of iron, of each one fluidrachm. The dose for adults is a teaspoonful every two to four hours, according to the urgency of the case. As soon as the symptoms begin to improve the dose should be decreased and the interval extended, but the remedy should not be discontinued until the throat is entirely free from the diphtheritic deposit. Dr. Alexander states that he has used this method of treatment constantly for several years, during which time he has lost but one case of diphtheria, and that one was not seen until the disease was too far advanced to be stayed by any remedy. He writes in conclusion: "It may seem that there is nothing remarkable in the above combination, as chlorate of potassa and tincture of iron are used by nearly everyone, but the union of the three articles combined in these proportions has produced very marked results. I will not attempt an explanation of the *modus operandi* of this medicine, but will leave it to those who are more competent; but if I can persuade any of my professional brethren to give this simple remedy a trial, I shall have accomplished my purpose."

TRAUMATIC TETANUS—RECOVERY.

In January of the present year, Dr. J. G. Stair, of Manteno, Ill., reported a case of traumatic tetanus which resulted fatally, notwithstanding a most heroic treatment with bromide of potassium, gelsemium, and chloral. A second case, which was recently under his care, has terminated in recovery. The patient, Mrs. M——, fell against an old corn cultivator, cutting the palm of the hand near the thumb on the rusty corner of one of the shovels or ploughs, forming part of the machine. The wound was about three-fourths inch in length and one-eighth inch in depth, caused the patient no anxiety, and had nearly healed without suppuration on the third day after the accident. At this time Mrs. M—— was seized with stiffness of the muscles of the left arm and the jaw, and pain, which started from the wound in the hand and extended up the arm to the jaw and the epigastrium. Soon the paroxysms became more general and involved all the muscles of the body; they continued for from one to two hours, and recurred at varying intervals of six to thirty-six hours. During the first week of the disease the temperature was 101° F., and the pulse ranged from 120 to 130. In the second week the temperature was from 99° to 99.5° F., and the pulse-rate between 90 and 100. The treatment consisted in the administration of bromide of potassium, chloral hydrate, and fluid extract of physostigma. These were given in succession until their physiological effects were observed. In addition, morphine was given in small doses as needed, to induce sleep. The wound was thoroughly cauterized with nitrate of silver and nitric acid, and covered with a soft poultice; it was freely incised several times and bled quite freely. A fly-blister was applied along the whole extent of the spine, and ice was placed from time to time over the lower portion of the back. Cascara and calomel were also given as occasion required. In two weeks the paroxysms ceased, and at the time of writing Dr. Stair reports the patient as having nearly recovered her usual health.

ACUTE ŒDEMA OF THE EPIGLOTTIS.

Dr. G. B. Hope, of No. 34 West Fifty-first Street, reports the case of a man, fifty-four years of age, who presented himself at the clinic of the Post-graduate Medical School, suffering from urgent dyspnœa. Laryngoscopic examination showed acute œdema of both ventricular bands rising high in the larynx, with the narrowest possible opening of the glottis, especially during inspiration. The swelling was most pronounced in the anterior portion, though pretty general throughout, and the cords were not visible in any part. Following the examination such a marked spasm occurred as seemed to threaten suffocation and to demand instant tracheotomy. The extreme urgency passed by, however, and as soon as a laryngeal knife could be procured the parts were freely incised. There was considerable hæmorrhage, and the relief afforded by the operation was immediate. There was no return of the œdema, and four days later the parts had resumed their normal appearance. Subsequent examination showed that the œdema was limited chiefly to the epiglottis and aryteno-epiglottic folds. The shape of the epiglottis was somewhat unusual, it being more than ordinarily short and broad, and when first examined had an appearance like that presented by the ventricular bands when largely infiltrated. The cause of the attack appeared to have been irritation, excited by the use of the finger in the throat to provoke vomiting. This case shows the readiness with which even extreme œdema may yield to free incisions, the necessity of the graver operation of tracheotomy being thus obviated.

HOUSEMAID'S KNEE—RECOVERY WITHOUT REMOVAL OF THE SAC.

Dr. Charles H. Carter, of Chicago, Ill., relates the case of a plasterer, aged thirty-four, who had received a fall three weeks before coming under observation, striking his knee against the edge of a board. No pain was felt until about a week after the injury had been received, at which time also a swelling was noticed. This tumor increased in size until it covered the lower two-thirds of the anterior surface of the patella, and was found to contain pus. There being no time for temporizing, Dr.

Carter proceeded to operate as follows: "With a bistoury I made an incision from above downward on the external side of the swelling, carrying it, with the aid of a grooved director, to the extreme lower limit of the cyst, so as to avoid leaving a 'pocket,' and to facilitate complete evacuation. The incision was made on one side, and from above downward, rather than from side to side, to prevent any gaping of the wound when the knee was flexed.

"After thoroughly emptying the sac by gentle pressure and gravity, I washed out the cavity with a two per cent. solution of carbolic acid in hot water, continuing until the water returned perfectly clear and unstained by either blood or pus. The time consumed by this part of the operation was probably ten minutes. I used hot water because that was more certain to dislodge any portion of pus which might, by its greater consistence, be retained around the edges of the sac, where the walls are reflected on the surface of the patella.

"Gently pressing out the water, but not taking any pains to thoroughly empty the sac, I carefully brought together the edges of the wound and hermetically sealed it with strips of silk isinglass-plaster, moistened with a ten per cent. solution of carbolic acid. Then, with the leg extended, I applied strips of mole-skin plaster to the whole knee-joint. I used strips about half an inch wide, and long enough to go about three-fourths around the joint, leaving the posterior surface uncovered.

"Commencing above the patella, I applied the first strip, drawing the ends strongly downward. The second slightly overlapped the first in front, but nearly covered the ends of it on the sides. The strapping was continued in this manner so that the strips firmly compressed every portion of the emptied sac, keeping the walls accurately in contact. The patient did not experience the least pain or discomfort in the part after the dressing was applied.

"Using no further means, except complete rest and low diet, I removed the dressing on May 5th, four and one-half days after the operation, and found the sac perfectly closed and not a drop of liquid to be felt in it.

"After remaining in-doors two days longer, the man went to his work, and has had no sign, as yet (June 30th), of a return of his 'housemaid's knee.'"

How an Opium Habitué was Cured.—Mr. S. T. Morton describes in the *Popular Science Monthly* his personal experience with opium, and denounces in vigorous terms the practice of treating opium-eaters by sudden withdrawal of the drug. He says: "I had been an *habitué* ten years, having reached at the end of that period the daily amount of thirty-six grains of gum-opium, taken only into the stomach. The 'habit' had been begun by a very small amount, and its increase had been extremely gradual. I knew not where to turn for help in effecting a cure: one thing seemed certain, it could not be done without help. At a venture merely, I called upon the late Dr. George M. Beard, feeling that, at any rate, I should be free from the risk of charlatanism; and I shall always remember him with gratitude, for it was through his recommendation that I placed myself under the care of another physician, who immediately undertook the treatment of my case. The gentleman whom, through the good fortune of Dr. Beard's introduction, I thus came to know, I found to be a young man, in the prime of good health and spirits, and one who at once inspired me with that confidence so important in such a case. His residence, it was manifest, was no ordinary 'institute' or 'asylum.' I was simply a courteously received guest in a private family." The patient was not placed under restraint, and was allowed to walk out and ride alone. His opium was gradually reduced until at the end of a week it was all withdrawn. He was subjected only to tonic treatment, and in the course of a few months was practically well. For a long time after, however, he was reminded at times of his old enemy.

Progress of Medical Science.

The Cutaneous Manifestations of Gonorrhœa.—M. Andret affirms that gonorrhœa may cause erythema of a nodose or papular kind and a rash resembling scarlatina. The author reports a case of "scarlatiniform erythema," and attributes such eruptions to the specificity and virulence of gonorrhœa, which, in his opinion, is a parasitic disease, depending on the presence of a special micro-organism. M. Raoul Mesnet, like M. Andret, looks upon gonorrhœa as a parasitic disease (*Thèse de Paris*), and, as such, liable to affect the skin like other infectious maladies. The greater part of the rashes commonly attributed to copaiba and similar drugs, the author considers to be really due to the gonorrhœa itself. Balsamic drugs alone, he maintains, cannot cause erythema, because they do not do so when given in other diseases than gonorrhœa; nor can the continuance or return of the eruption be procured by the administration of the drug even in large doses. Gonorrhœal eruptions are polymorphous (nodose, scarlatina-like, measles-like, etc.), and generally occur only in patients who have other symptoms of infection. They are usually accompanied by fever, and sometimes by a general condition of some severity. These eruptions cannot be dependent on reflex vaso-motor disturbance, which Lewin believes to be their cause; they are probably due to the presence of the gonorrhœal micro-organisms in the skin.—*London Medical Record*, June 15, 1885.

The Anæmic State.—At a recent meeting of the Brighton and Sussex Medico-Chirurgical Society (*The British Medical Journal*, July 4, 1885), Dr. Joseph Ewart read a paper on the anæmic state. This was manifested as an antecedent, accompaniment, or sequel, of specific fevers and "constitutional" diseases, of many local disorders, and of derangements which interfered with the nourishment of the blood or its depuration. As regarded the white and red corpuscles, it was probable that the same mode of genesis which led to their evolution in the blastema of the area vasculosa of the embryo, continued to insure their renewal and repair during their fully developed condition in thoroughly oxidized blood. Why should it be doubted that the red corpuscles possessed independent and self-reproductive powers? They were the analogues of the lungs, modified in structure, constitution, and distribution, so as to effect the interchange of oxygen and carbonic acid in the minutest recesses of the economy. The various phases of the anæmic state were then detailed; and, with regard to treatment, it was needful to note diathesis and temperament. In most cases, regulation of the bowels, improved hygiene, and open-air exercise, sufficed, especially if coupled with removal of the cause. In others, ferruginous preparations were demanded; the necessity of keeping the bowels free by means of salines in all cases of constipation being remembered. It had often seemed to Dr. Ewart, in managing malarial and other forms of anæmia, in which there was frequently manifested great intolerance of steel, that changing the particular preparation employed, a reduction of the dose, or a diminution of the number of doses administered in a given period, sometimes sufficed to get rid of the fulness in the forehead, headache, indigestion, and gastric or intestinal irritation attributed to its use. But, in the main, in such cases, and they were numerous, perhaps the best plan was to give very minute doses indeed; to assimilate them, in this respect, as much as possible to the condition in which they were found in chalybeate waters in a most diluted form, so that they might be taken between meals in large quantities of water during those periods of the morning and afternoon when out of-door exercise could best be taken. In summer, Dr. Ewart invariably recommended such persons as could afford it to try the excellent chalybeate springs of St. Ann's Well, Brighton, Tunbridge Wells, or Harrogate;

or the pure iron waters of Schwalbach or Spa; or the compound iron springs of Pyrmont, or St. Moritz, etc., under the direction of one of the physicians on the spot, and with the best results. Digestion, assimilation, and the nutrition of the blood, as regarded both albuminous material and the red corpuscles, were promoted by good but not too rich food, by drinking of the mineral waters, by open-air exercise, suited to the growing capabilities of the patient under the most agreeable surroundings of fine equable weather; by brilliant sunlight, tempered by abundance of shade; by society, and the best of music. The same mode of management was applicable to chlorosis, also, in anæmic Anglo-Indians, who had returned to their native country after long residence in or near the tropics; but very free purgation to remove portal plethora in such patients was necessary when the treatment was conducted in this climate. In the winter there was often practically no alternative. But in summer it was better to recommend them to drink, first, the saline waters of Carlsbad or Homburg on the spot, and to wind up with a course of any of the chalybeate springs already mentioned.

The Criminal Responsibility of Drunkards.—The Paris correspondent of *The British Medical Journal* (July 11, 1885), writes that M. Mottel, at a recent meeting of the Académie de Médecine, treated the important subject of the responsibility of criminal drunkards. Crimes, murders, etc., committed when the perpetrators are under the influence of drink, are much on the increase. Alcoholism at the present time presents unusual characteristics. M. Mottel believes that MM. Dujardin-Beaumetz and Audigé's researches explain this. Manufactured spirits currently sold are more toxic than pure vinous alcohols; they contain empyreumatic substances, which exercise a most dangerous influence on the nervous system, which is manifested by sudden fits of frenzy, and savage and brutal impulses. Magistrates are at a loss how to judge a criminal who suddenly commits a crime without any reason or previous intention. If the momentary delirium were the result of a former cerebral lesion of alcoholic origin, the medical expert's evidence would give some clue; but after the momentary influence of these manufactured spirits has passed away, the drunkard is in a normal condition, and no symptoms can be detected suggesting the probability of a return of mad impulses.

Trigger-finger.—Several Italian surgeons have recently published observations on the *dita a scatto*, or trigger-finger, first described by Rusconi in the *Gazzetta degli Ospitali*, in 1878. This affection consists in a sudden check to voluntary extension or flexion of a finger, only overcome by a violent effort, or by the aid of the other hand, when the finger suddenly completes the desired movement with an audible snap. It most frequently attacks the thumb and ring-finger, but has been observed in other fingers, in several simultaneously, and also in the toes. The patients are generally between forty and sixty years of age, and men are less frequently affected than women. Rusconi has collected thirty-six cases. Romei has since (1884) described another case in the same journal above quoted; the patient was a woman, sixty-five years of age, and the ring-finger was the part affected. Solaroli gave notes of a severe case, where the great toe was involved, in a strumous housemaid, twenty years of age. In one-third of the cases already observed, rheumatism was the predisposing cause; in others, there was a distinct history of injury; in some, the origin of the disorder could not be traced. There is generally severe pain, and in the cutaneous fold between the first phalanx and the palm, a thickening has been detected. Possibly this condition may indicate some inflammatory change in the tendons or their sheath, or even a loose cartilage, as in the knee-joint. Notta and Nélaton speak of a distention of the blind end of the synovial sheath at the free border of the palmar fascia, observed when the affected finger moves in the act of writing; some distinct protuberances have also been detected on the bulging flexor tendons. These swellings appear to press against the palmar fascia, and hinder further movements of the tendons. Notta has found a thickening of the long flexor tendon in a "trigger-thumb," and attributes the sudden check to the transverse aponeurotic fibres which pass across the sheath over the metacarpo-phalangeal joint. "Trigger-finger" is an obstinate disease, and a great hinderance to work. Passive motion, fixing the finger in splints, shampooing, and electricity, have been tried as remedies. As surgical operations, excision of the tuberosities, tenotomy, and subcutaneous division of the palmar fascia, have been proposed; but none of these measures have proved of permanent benefit.—*The British Medical Journal*, July 4, 1885.

Treatment of Asthma with Pyridin.—Professor Germain Sée has recently communicated to the Paris Academy of Sciences a valuable series of observations on the action of pyridin in the treatment of both neuro-pulmonary and cardiac asthma. Pyridin is a colorless liquid, which evaporates when exposed to the air, and possesses a very penetrating odor. This substance has been discovered by chemical analysis in the products of dry distillation of a variety of organic substances; in such alkaloids as quinine and morphine; and by Wohl and Eulenberg in the products of tobacco-smoke. Various anti-asthmatic cigarettes and burning papers have been found to owe all their virtues to this uniform base, which is developed by the combustion process. The best mode of application consists in evaporating a drachm or more of the liquid in a close room in which the patient sits, for twenty minutes or a half hour, three times daily. Absorption is immediate, as the pyridin appears almost at once in the urine. An almost immediate diminution of the oppression takes place, respiration becomes free, and the heart-beat calm and regular. Immediately after the séance, or an hour later, many experience a tendency to sleep. Usually after the second or third séance the wheezing in the chest disappears. Professor Sée observed the effects of pyridin on fifteen patients, five of whom were affected with heart disease. In all cases decided benefit was noted. In three cases of nervous asthma the attacks disappeared completely after from eight to fifteen days of treatment. The heart cases were immediately and markedly benefited. From these observations the author concludes that all forms of asthma are more benefited during the attack by pyridin than by morphine or any other palliative treatment, but that in the iodides we have the most efficacious curative means.—*Bulletin Gén. de Ther.*, June 30, 1885.

The Contagion of Mumps.—The Paris correspondent of the *British Medical Journal*, writes that M. Jaccoud, in a recent clinical lecture at the Hôpital de la Pitié, drew attention to a case of mumps presenting infectious symptoms. The patient entered after the first symptoms had abated. The swelling of the parotid glands had diminished; the right testicle was much swollen and very painful. The temperature was very high, at night reaching 104.2° F.; the subsequent evenings it reached 108.8° F. Endocarditis, affecting both the sigmoid and mitral valves, set in. Dr. Jaccoud regarded this complication as an indication of the infectious character of this case of mumps. Gradually the symptoms disappeared; but the cardiac *bruits* remained, though much enfeebled. M. Netter examined the blood of the patient, and found that it contained microbes. Dr. Jaccoud enumerates the three following symptoms as clinical indications of infection: fever, endocarditis, and transient albuminuria. M. Auguste Ollivier, in a communication to the Académie de Médecine on the contagious character of mumps, stated that the contagious character of this affection can be no longer doubted. MM. Capitan and Charrin have made some researches to ascertain the agent of this contagion, and assert that it is a special micro-organism contained in the

blood and saliva. Inoculations made with it furnished negative results. M. Barth, in a recent thesis, published notes of a serious case of parotiditis in Dr. Bouchard's wards. Microbes were present in his urine and saliva. In the urine and saliva of a male child, aged eleven, suffering from mumps, Dr. Ollivier observed epithelial cells, lymphatic corpuscles, short rods, and micrococci, dispersed in couples or in fours. Zoöglœa were also present, but gentian-violet did not stain them. The urine was highly colored, limpid, free from albumen, and contained a considerable quantity of micrococci, arranged in small masses, two together; rods and bacteria were not so abundant as in the saliva. The saliva of children not suffering from mumps, examined by Dr. Ollivier, was free from rods, but contained micrococci and zoöglœa, which were stained by gentian-violet. In their urine there were neither rods nor micrococci. M. Ollivier afterward examined the saliva and urine of children suffering from parotiditis, and detected the presence of micrococci, diplococci, and zoöglœa.

Extemporaneous Examination of Woman's Milk.—Dr. Hélot, in the *Union Médicale de la Seine Inférieure*, recommends a simple method of determining the quality of human milk. He undoubtedly accords superiority to chemical analysis, but as this process is so long and difficult the common practice has been to rely upon the appearance of the milk. Dr. Hélot's method consists in comparing the number of drops in a given volume of distilled water at 60° F. with those of the same volume of milk. Good milk, such as produces a mean increase of an ounce per day in the child's weight, gives thirty-five drops in the same volume which, of water, gives but thirty. If the milk be of superior quality the volume may yield as high as thirty-eight drops. If, on the contrary, but thirty-three or less are obtained, the milk should be mistrusted. Both breasts should be examined while the nursing is going on.

Diaphoretic Treatment of Puerperal Eclampsia by Hot Baths.—Dr. Breus reports (*Archiv für Gynäkolog.*, xxi. i.) eleven cases of puerperal eclampsia treated by the hot bath, with ten recoveries. He had previously treated six cases by this method, losing in this series, likewise, one case. He first places the patient in a bath of 100° F., and gradually increases the temperature from two to four degrees. He then envelops the patient in blankets to excite an abundant diaphoresis. Of these eleven women, four had had convulsions at the commencement of labor, two during gestation, one at the moment of delivery, and four after delivery. The author affirms, from his experience with these seventeen cases, that neither abortions nor hemorrhages are to be feared from the employment of the bath, and that when the presence of albumen in the urine indicates a threatened complication, the bath constitutes an excellent prophylactic means. One of the cases reported was that of a primipara, aged twenty-six, who was attacked with œdema and albuminuria. In the eighth month baths began to be given After taking forty-five, she was successfully delivered of a large and healthy child.

Stammering and Stuttering.—Alex. J. D. D'Orsey writes to the *British Medical Journal*, June 27, 1885, that as much misapprehension exists concerning the above subjects, the following may be of interest: 1. Speech, or articulated voice, depends for its perfect production on vigor of mind, on sound natural organization, and on due training of the vocal and articulating apparatus. 2. Stammering is inability to articulate, marked by slowness, stoppage, hesitation, and indistinctness, but not with repetition; whereas stuttering consists in a painful repetition of the same consonants, often attended by flushing and facial contortions. 3. Stammering and stuttering may sometimes be caused by organic defects, such as cleft palate, harelip, enlarged uvula, inflamed tonsils, etc.; but these impediments are far more frequently due to functional causes, that is, habit, imitation, heredity, etc. Nervousness is often the consequence, or concomitant of stammering, rather than its cause. Organic effects must, of course, be treated medically or surgically, but the subsequent cure belongs to the elocutionist, while functional derangements (wrong action of the voice apparatus) are peculiarly his province. 4. The sooner the curative process begins the greater is the prospect of success. What is easily eradicated at an early age becomes hard to remove at a later period; though at any time of life, alleviation, if not cure, can be assured as the result of perseverance. "He will grow out of it," is a fatal saying. A fair time ought to be given, according to the nature of the case; for "a few lessons" cannot reasonably be expected to undo the mischief of many years; and the teacher is often accused of failure, when the blame is solely attributable to the patient or the parent.

Alkaloids in Urine.—The Paris correspondent of the *Lancet* (July 11, 1885), writes that a short time ago Drs. Bouchard and Poulet, after a series of researches undertaken by them conjointly, announced the existence of alkaloids in normal urine. Dr. A. Villiers has since studied the subject, and, in a paper lately read by him at the Academy of Sciences, has arrived at a different conclusion—that is, that alkaloids exist only in abnormal urine, and that in the normal condition this liquid does not contain any alkaloidic substance; that in the course of a great number of maladies, even those that are slight, alkaloids—the proportions and toxic properties of which are probably very variable—form in certain organs, pass into the current of the circulation, and are eliminated by the kidneys. Between this formation and elimination a struggle takes place; if the elimination is less rapid than the formation, a veritable intoxication supervenes. In this line of argument Dr. Villiers attributes a great number of fatal cases to the existence of lesions of the kidneys, produced either by some extraneous cause or even by the action of the poison on these organs, lesions diminishing their eliminative action. The ingestion of large quantities of water in the organism may, in a great number of cases, facilitate the elimination of alkaloidal substances, and this is probably the real mode of action of the greater part of the ptisans or infusions administered in divers maladies.

Leprosy with Invasion of the Tongue.—Dr. Campana reports the case of a youth, aged fifteen, of leprous parents, who had tubercles and macules of leprosy on the face and legs. The tongue was also involved, the disease there being manifested by little papilliform tumors grouped together in an oval patch the size of a cent, slightly raised and with roughened surface. These little tumors varied in size from that of a lentil to that of a hemp-seed. Some were conical in shape, others rounded, they were red in color, and painless. One of these tumors was removed and examined under the microscope, when numerous bacilli characteristic of leprosy were found.—*Revue Médicale*, June 13, 1885.

Perforating Ulcer of the Hand.—At a recent meeting of the Surgical Society of Paris, M. Terrillon (*Revue Médicale*, June 13, 1885), presented a patient, aged twenty-six, who had on both hands ulcerations surrounded with thickened epidermis resembling exactly perforating ulcer of the foot. The lesions were surrounded with an anæsthetic zone. There could be no doubt of their origin from a central nervous lesion, and the patient also had other symptoms pointing unmistakably to locomotor ataxia. M. Terrillon had also presented a similar case at a previous meeting. M. Trélat recalled an observation previously made by him, of the relation between perforating ulcer and a central nervous lesion, and stated that he has seen the ulcers upon both hands and feet in the same subject, who was ataxic.

Herpes following Operations on the Teeth.—In a paper in the *Journal de Médecine de Paris*, of June 14, 1885, Dr. T. David writes of a form of so-called traumatic herpes which he has observed after operations upon the teeth or with dental caries. The eruption is seen more often in women and young people, and is seated upon the mucous membrane of the gums, lips, or cheek, or upon the skin of the face. It may be confluent or discrete, and may or may not be accompanied with fever. When there is an elevation of temperature, the eruption may be regarded as a local manifestation of hepatic fever determined by the dental irritation. When there is no fever, the herpes is to be regarded as due to nervous troubles excited by the traumatism of pulling or filling a tooth, or by the irritation arising from the carious process. Dental herpes, when accompanied by fever, swelling of the face, and redness of the skin, may lead to a diagnosis of erysipelas. The affection is otherwise of trivial importance, and disappears spontaneously in a few days.

Orchitis following Catheterization.—At a recent meeting of the Société Médico-Pratique, Dr. Barette read an interesting paper upon the different forms of orchitis due to urethral catheterization, of which the following are his conclusions (*Journal de Médecine de Paris*, Nos. 23 and 24, 1885): 1, Patients with stricture or enlarged prostate are the more exposed to inflammation of the testicles after catheterization the older they are and the more vascular is the urethral mucous membrane; 2, the inflammation of testes and epididymus may be simple or suppurative; 3, in all cases the point of departure of the trouble is a lesion at or near the ejaculatory orifices; 4, starting from this point the inflammation seems to advance by way of the lymphatics of the seminal apparatus, and to thus gain the testicle and tunica vaginalis; 5, whether the orchitis shall be simple or suppurating seems to depend in great measure upon the condition, whether normal or otherwise, of the urine, and upon the nature and extent of the pre-existing lesions of the genito-urinary apparatus.

Resorcine in the Treatment of Whooping-cough.—In a recently published monograph, Dr. Moncorvo, of Rio de Janeiro, reaffirms the opinion, advanced by him in a previous work, that pertussis is a local disease and that it is not primarily an inflammation of the bronchial tubes. Bronchitis may coexist, he admits, with whooping-cough, but when it does so it is to be regarded as a complication, and by no means an essential part of the disease. He further maintains that the affection is apyretic in its course, leaving out of consideration the complications which may occur, and cannot therefore be classed, as it is by some writers, among the fevers of childhood. The writer holds to the view, and it is upon this that his treatment is based, that pertussis is a parasitic disease confined to the larynx, essentially local, and to be combated by local measures. His treatment consists in the application of resorcine, in one or two per cent. solution, to the larynx at intervals varying from two to twelve hours, according to the severity of the case. The first application may cause an apparent aggravation, but improvement soon follows, and in a short time the paroxysms cease. The author insists upon the necessity of using pure resorcine, occurring in silvery-white needles, very soluble in water, possessing but a faint taste, and free from any odor of benzine or creosote. The author reports upward of forty cases in which resorcine was used, in every one of which recovery took place in a very short space of time.

Poisoning from the Bite of a Rat.—M. Millot-Carpentier reported to the Paris Academy of Medicine the case of a young boatman on the Saint-Quentin Canal who was bitten on the hand and lip by a rat. The wounds healed promptly, but fifteen days later symptoms of lymphangitis appeared, but soon went away again without suppuration, and then purpuric spots appeared upon the integument. The latter affection was accompanied by acute anæmia, prostration, muscular atony, and irregular febrile attacks. At the same time there were singular nervous troubles, intense dysphagia, congestion of the face, laryngeal whistling, temporary inability to speak, swallow, or breathe, and a frothing at the mouth. These attacks were attended with an increase of fever, and left the patient in a condition of extreme prostration. Sometimes the attacks were preceded by an aura starting from the cicatrix in the hand and passing up to the throat. A cure followed the employment internally of permanganate of potassium and sulphate of quinine with tonics and a nourishing diet. The author of the communication considered the case to be one of poisoning by an animal virus.—*L'Union Médicale*, June 21, 1885.

Euphorbia Pilulifera in Asthma.—Euphorbia pilulifera is a plant quite common in Brazil, and has recently taken rank with other drugs employed in asthma. Dr. Marset reviews its properties and mode of administration in the *Bulletin Général de Thérapeutique*, March, 1885. The active principle of the plant is soluble in water and dilute alcohol, but only slightly soluble in ether and chloroform. In small doses it kills animals, by arresting the respiratory movements and heart-beat, which, however, are first accelerated under its influence. Its effects are not cumulative. It appears to act directly on the respiratory and cardiac centres, leaving all other organs intact, and seems to be eliminated by the liver. Locally it is without action on the skin or mucous membrane, excepting that of the stomach, which is irritated by it. It produces good results in the attacks of dyspnœa caused by asthma, emphysema, or chronic bronchitis. It should be employed in daily doses equal to not more than fifteen grains of the dry plant, and taken largely diluted, preferably at the beginning of a meal.

Bromide of Zinc.—Dr. Testa has recently published an interesting study on the action of bromide of zinc, to which he appends the following conclusions (*Revista Médica de Sevilla*, June 15, 1885): 1. This remedy in small doses diminishes sensation, and in large doses destroys the power of voluntary motion, leading thus by its double action to complete paralysis. 2. These effects, unless the dose has been very large, gradually diminish and disappear spontaneously. 3. Bromide of zinc arrests the frog's heart in extreme diastole, but this is a late symptom. 4. The action of this drug resembles more that of zinc than of bromide of potassium. 5. The action of the zinc is, however, modified by that of the bromine, since somnolence, which is caused by it, is not an effect of zinc. 6. The remedy acts first upon the peripheral extremity of the sensitive nerves and then upon the spinal nervous centre. 7. That it also acts upon the cerebral centres is evidenced by the somnolence caused by it.

Strychnine in Acute Alcoholism.—Dr. Lardier has long employed strychnine in the treatment of delirium tremens, and regards it as the best remedy which we possess for this condition, as, in fact, a veritable specific. He insists upon the necessity of giving the drug in large doses. In one case he had given granules containing each $\frac{1}{13}$ grain every two hours for several days without any appreciable result. He then increased the number of granules and also administered the drug hypodermatically, giving in all $1\frac{3}{4}$ grain in the space of twenty-three hours. The result was a most happy one. The patient soon fell into a refreshing sleep, never exhibiting the slightest symptom of strychnine poisoning.—*Journal de Médecine et de Chirurgie Pratiques*, June, 1885.

Treatment of Nasal Polypi.—The following powder is recommended by a French writer as oftentimes efficacious in the treatment of polypi of the nasal passages: Morphine hydrochlorate, $1\frac{1}{2}$ grain; powdered cubebs, $2\frac{1}{2}$ drachms. A pinch of the powder to be snuffed up five or six times a day.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, August 15, 1885.

THE PHYSIOLOGICAL ACTION OF HYDROCHINON.

THE recent successful use of hydrochinon as an antipyretic, in St. Luke's Hospital[1] and elsewhere, has led to a fuller study of the physiological action of this new drug. A two per cent. aqueous solution of hydrochinon immediately and permanently stops the active movements of fresh- and salt-water amœba, of animalculæ, and of a great variety of bacteria. The common rod-shaped bacteria of urine are to some extent affected, but their movements and reproduction do not cease entirely. Fresh urine to which a two per cent. solution has been added in equal bulk does not ferment so rapidly as it otherwise would. Bacteria do, however, develop in it, and in a few days a bright-green fungus appears upon the surface, while the urine becomes dark-red, owing to oxidation of the hydrochinon. Five minims of a two per cent. solution of hydrochinon injected into the aorta of a decapitated land-tortoise produce in three or four seconds violent convulsive movements and tremors of the entire body. These movements are irregular and very rapid, and they affect different groups of muscles successively.

A piece of fresh muscle moistened with the solution shows increased irritability. The heart beats regularly at first; subsequently the rhythm is disturbed; the force of the systole is increased, and its duration is prolonged.

In the rabbit a few drops of a two per cent. aqueous solution, placed in the eye, causes irritation and hyperæmia, with slight swelling of the conjunctiva. This effect is, however, very transient. A drachm of the two per cent. solution may be swallowed without effect, but .25 gramme, given hypodermatically (in hot water) to a rabbit weighing seven hundred and seventy-five grammes, causes a series of interesting symptoms. In from two to five minutes the animal becomes much excited and restless, its ears, lips, and alæ nasæ twitch violently, the respirations become very rapid, and in eight or ten minutes the fore-legs, and subsequently the hind-legs, exhibit violent clonic spasms. The animal tries to walk, but its efforts end in a sprawl.

The eyelids and lips, and, in fact, all the muscles of the body, are violently affected; the teeth chatter, and the saliva is considerably, the tears slightly, increased; the bowels move frequently, and there may be micturition; priapism also occurs.

[1] Hydrochinon, a New Antipyretic, by Francis P. Kinnicutt, MEDICAL RECORD, May 30, 1885.

No longer able to stand, the animal falls upon the side and vainly kicks in the air. Slight opisthotonos may occur, but the muscles do not pass into tonic spasm until just before death. Cutaneous sensibility is not diminished, and reflexes appear increased. Capillary congestion and heat of the ears is mentioned by Brieger,[1] but is not always observed. The clonic spasms having lasted an hour and a half, the animal suddenly recovers completely, though it is naturally weak for an hour or so longer. No after-effects are noticeable, and no abscess follows the injection. The convulsions are of spinal origin, as they take place in a decapitated animal.

During the active convulsive movements the temperature rises to 104.5° to 105° in the rectum. This is not of much moment in the rabbit, whose normal rectal temperature is about 101° F. Mental excitement, movement, or defecation readily affect this temperature by several degrees. The pulse remains full, regular, and very rapid throughout.

If a larger dose be given, say .5 gramme, to a rabbit weighing nine hundred grammes, the symptoms are the same, but death occurs in a tonic convulsion (opisthotonos) in about ten or twelve minutes. The pupils appear dilated at first, they react normally, and just before death contract somewhat. The heart continues beating for some time after the animal has ceased to breathe, but the action is labored, and when removed from the body it ceases to beat sooner than usual. Rigor mortis occurs at once, and is well marked. The blood coagulates promptly; the cerebral meninges do not appear congested, nor do the lungs; the kidneys are hyperæmic, and the mesentery is congested; peristaltic movement is enhanced, and it persists with greater activity than usual after death in both stomach and intestines. Other organs are normal.

Hydrochinon occurs in grayish-white acicular crystals, having a slightly bitter taste, and a neutral reaction. It is moderately soluble in cold water, readily soluble in hot water, alcohol, ether, and in acid solutions. The usual adult dose, as an antipyretic, is fifteen to twenty grains, best given in alcohol. Forty grains have been taken without disagreeable effects. Hydrochinon is at present somewhat dearer than quinine. Thus far only two writers have reported their clinical experience with the drug, but their results have been so encouraging that much benefit may be expected from its further employment.

Dr. Kinnicutt's cases were fully reported in the RECORD (loc. cit.). The other article, by Seifert, occurs in the *Berl. Klin. Woch.*, No. 29, 1884. Seifert used hydrochinon with benefit in fifteen cases of typhoid fever, and in twenty-three other cases of severe fever of various types.

DANGERS OF MEDICAL SPECIALISM.

UNDER this title, Dr. H. B. Donkin writes, in the *Fortnightly Review* for July, an interesting reply to Dr. Morell Mackenzie's contribution to the preceding number of the same journal. This latter article, it will be recollected, we noticed editorially some time since. The tone of Dr. Donkin's reply is forcible and dignified,

[1] L. Brieger: Dihydroxybenzol; Archiv für Anat. u. Physiol., 1879, supplement-band, p. 67.

though at times sarcastic, and in one or two instances decidedly caustic. He goes all over his opponent's ground, and controverts him at nearly every essential point. He says: "The real object of his (Dr. Mackenzie's) attack is the main body of the medical profession, with the Royal College of Physicians in the fore-front of the opposing ranks," and he denies that there has ever been any overt opposition to specialism in the wide sense of devotion of special attention to certain subjects.

According to Dr. Mackenzie, specialism is the "concentration of a man's best powers on a single object." "He may," says Dr. Donkin, "for object read 'organ,' and if his premises apply to medical practice at large, as well as to the occupations he cites as analogous, it must be shown that the whole territory of medicine can be subdivided, without injury to its cultivation, into small and separate fields; but it is equally clear to those who, without technical knowledge, even for a moment seriously contemplate that territory—the human body—that no such division can take place. . . . The body is an organism, not a mechanism; it cannot be studied piecemeal, . . . and he who has the widest knowledge of that body, and of its diseases and its disorders, is best able to find out what is the matter with his patients, and consequently (with certain exceptions) to tend to help them toward recovery."

Dr. Donkin then proceeds to sketch what would be the state of affairs if such a division of labor should occur as would logically result from the carrying out of his opponent's principles. Suppose, he reasons, all physicians were specialists, all high-minded men, each careful not to intrude upon the province of the other. A patient comes complaining of heart-trouble: now, we know that some of the gravest cardiac maladies often exist without any premonitory symptoms, while a slight physiological disturbance may cause very grave ones; furthermore, that often the brunt of the trouble is borne by some organ remote from the heart: to whom, he asks, are such patients to go? which specialist can claim them as his legitimate clientèle? "Surely," he adds, with a side-thrust at his opponent, "the heart is at least as worthy an 'object' as the larynx," and he drives the blade home by continuing: "Laryngology offers, from the facility it gives of actually seeing a part of the body beyond the patient's own ken, a strong temptation to those who are not immaculate to fabulate when they do not find disease."

Dr. Donkin does not regard popular sentiment in regard to specialism, particularly in America, as either a safe or reliable guide to a true estimate of its worth. Nor does he regard Dr. Mackenzie's analogies between the medical and the other professions as holding. According to him, sanitary engineers and electrical engineers (alluding to one of his opponent's analogies) have simply two things in common—a mere part of a name, and the fact that their respective sciences deal with material things which can be seen, felt, and calculated with generally mathematical exactness. Not so, however, with the human body, that variable factor with which the physician has to deal. The specialist has already branched out from his logically legitimate field, and "'Diseases of the Throat' now include almost every affection, be it local or general, accidental or acquired, which affects a gratuitously limited area between the level of the chin and breastbone."

Diagnosis he regards as the great point of the whole matter. If that is accurate, we shall nearly always harmonize in the matter of treatment. Such accuracy is in direct proportion to the wideness of our knowledge and experience. Finally, he partially begs the whole argument by saying: "It is clear to all who know anything of clinical medicine and pathology, that the men who pay special attention to special organs of the body are not those best qualified to investigate or to treat even those diseases that are assumed to belong to those special organs which but rarely suffer alone, or still less to throw light on indefinite or obscure cases."

There is considerable animus in both the papers above alluded to. Here in America we are not attempting to solve the problem of specialism on purely theoretical grounds, but are letting the matter take care of itself, with, on the whole, fairly creditable results. Specialists have appeared in proportion to the demand for them. We believe that every practitioner should know enough about the pathology of special organs to know when special measures are demanded—in other words, when to invoke the aid of the specialist. Furthermore, we believe, and experience has shown, that the successful specialists of to-day are those who have laid a broad foundation in years of general practice, and who, while speaking one dialect, as it were, of the language of medicine, are yet to a creditable extent conversant with the entire tongue.

ACCURATE TEST-TYPES.

An interesting paper concerning test-types was read by Dr. W. S. Dennett at the Ophthalmological Society, which met at New London, last month. Attention was called to the fact that the test type ordinarily in use was inaccurate for the purpose of testing visual acuteness. Of the ten or dozen letters of equal height composing a line on the test-card in general use, some with an emmetropic eye can be seen clearly at half the distance of others. Oculists up to the present time have been testing eyes at a fixed distance, not understanding the *distance value*, so to speak, of each of the letters. This has been determined by Dr. Dennett after a series of experiments performed in the following manner: The light was excluded from a bowling alley except that given by Edison lamps, whose illumination was so arranged as to give an equivalent of one candle power at a distance of ten centimetres from the type. The letters were made of India ink on white paper. Each letter was properly arranged and the observer slowly advanced to the place where he could distinguish it from one or two of those that it most resembled, and with which it was most likely to be confused. This plan was found to work better than exploring all the letters at once. The result was A, L, U, V, and I were always seen at the greatest distance, and B and S at the least.

As a result of these experiments Dr. Dennett exhibited to the Society a test card on which were displayed letters of a size made in accordance with mathematical laws, to give them all a uniform value.

It is not a little singular that it should have been left until to-day to make the demonstration of the inaccuracies

of a test which has been constantly employed by oculists for twenty years.

It may be remarked that many who make the eye a specialty have recognized the fact that some letters of the same size are much more easily distinguished by patients than others, but Dr. Dennett has discovered the true scientific reason and has placed the matter on a basis of physics and accuracy.

DISPENSARIES—THEIR USE AND THEIR ABUSE.

From time to time there appear in The Record and other medical journals complaints in regard to the abuse of medical charity in New York, and questions as to how it can be regulated. Every physician with a dispensary practice recognizes the fact that many people who could pay a doctor receive medical advice free. It requires but little experience to diagnosticate "the dispensary tramps." They are of every sex and age, and have made the rounds of almost all the dispensaries.

They become connoisseurs of doctors and their methods of treatment. Some of them are very much puffed up with pride if their ailments have been such as to draw the attention to them of distinguished members of the profession, and to have brought them forward in college clinics.

The patients are not the ones to blame for the existing state of free medical services. It is the physicians who attend the clinics, most of whom are professors, instructors, or assistants at clinics held at the colleges or post-graduate institutions. To them patients who will well illustrate diseases dwelt upon by lecturers in the various departments are at a premium. Patients are sought after with eagerness, and devices resorted to to secure them. It is often a matter of how to induce people to come to the clinics rather than how to make them stay away.

Dispensaries, too, are multiplied every year. Once started, the managers desire to make them successful. Success is measured by numbers. Every inducement is offered to the moderately poor in the city to avail themselves of free medical services.

Therefore, if there is to be a reform in this matter, the doctors must give up wishing to hold large clinics—wishing to display to their followings of graduates and undergraduates a variety of cases. Strict inquiry into the circumstances of the patients who apply for aid will do this. Some it will drive away from the clinics to give up all notion of doctoring; others it will send to the physicians who depend upon this class for the small fees which enable them to obtain a foothold among the numerous struggling practitioners of New York.

ANTI-VACCINATION.

The stubbornness of the British character is well shown in the martyr-like spirit with which the anti-vaccination people persist in their determination not to submit to this preventive to contagion from small-pox.

The *Lancet* reports that small-pox is spreading in a very serious way through London and other neighboring cities, and that it is due largely to this unwillingness to be vaccinated.

Occasionally the power of the courts is invoked to compel persons to submit themselves and their families to vaccination, but it frequently happens that the self-opinionated Briton will allow himself to be imprisoned rather than yield. The agitation on the subject goes on vigorously, and there are some educated people who still insist that vaccination is harmful rather than beneficial.

In this country vaccination is generally required, but there is little opposition manifested even when the vaccination has to be done under the direction of the Health officers.

SOME RECENT STATISTICS REGARDING CANCER OF THE TONGUE AND MOUTH.

The report of the Middlesex Hospital, London, for 1883, contains tabulated histories and statistics of 9 cases of cancer of the tongue, 37 cases of cancer of the breast, 41 cases of cancer of the uterus, 2 cases of cancer of the mouth, 8 cases of cancer of the lip, and 6 cases of cancer of rectum and anus, with 18 miscellaneous cancers. This makes a total of 121. Of these the cancers of the tongue (9) and mouth (2) constitute over 12 per cent., a rather larger proportion than the average.

Of the cancers of the tongue eight occurred in men and one in a woman. The cancers of the mouth occurred in men. The age ranged from 35 to 72, eight of the eleven cases being over fifty-one years old.

Very little information is given as to the cause; a history of syphilis was obtained in two cases, and in one of the cases of cancer of the mouth the patient had been a great smoker of a clay pipe. No family history or constitutional taint appears to have existed in any of the cases.

Five of the cases died when in the hospital. In one of these (tongue-cancer) the disease lasted twelve months, there being no operation. A second patient, who had had the disease only four months, died suddenly while under nitrous oxide gas. A third patient, who had been operated on twice, died in thirteen months after the disease first appeared. A fourth patient lived for three years after first noticing some glandular enlargements in the neck. In a fifth case, in which the floor of the mouth, the lower jaw, and the tongue were involved, the patient lived for a little over a year.

Missouri State Board of Health.—Under date of July 25th, the secretary of the Missouri State Board of Health has issued a circular to the public and the local boards of health concerning the use of impure water by the manufacturers of soda and mineral waters. It states that much of the water is obtained from unknown or suspicious sources, and that there is strong probability that disease may be caused by its use. It recommends that dispensers of such liquids ask the manufacturers from whom their stock is obtained to secure a certificate from their local health authorities declaring the sources from which the water used in the manufacture or preparation of their goods are derived to be pure and wholesome.

The services of the members of the New York Pension Board have been dispensed with by orders from the Commissioner of Pensions. The members of the late Board were Drs. S. S. Burt, A. B. Judson, and W. O. McDonald. The new Board has not as yet been formed.

News of the Week.

The Pennsylvania State Board of Health.—The new State Board of Health and Vital Statistics of the Commonwealth of Pennsylvania was organized at Harrisburg, July 2d. Dr. E. W. Gerner, Health Officer of Erie, was elected president, and Dr. Benjamin Lee, of Philadelphia, secretary. The first session was taken up mainly with the discussion and adoption of by-laws. Regular meetings will be held on the Second Wednesdays of May, July, and November. At the July meeting the election of officers will be held. At the November meeting an annual report will be adopted to be presented to the Governor on the first Monday in December, according to law. At the May meeting a public address will be delivered on some sanitary topic. Standing committees were established as follows: Executive Committee, headquarters in Philadelphia, Chairman, Dr. P. Dudley; Committee on Registration and Vital Statistics, Chairman, Dr. J. F. Edwards; Committee on Prevalent Diseases and Supervision of Traffic and Travel, Chairman, Dr. J. F. Edwards; Committee on Water-supply, Drainage, and Topography, Chairman, Rudolph Hering; Committee on Adulteration of Foods, Beverages, and Drugs, Chairman, not named; Committee on Public Institutions and School Hygiene, Chairman, Dr. McClellan; Comittee on Sanitary Legislation, Rules and Regulations, Chairman, Dr. P. Dudley; Committee on Mines, Poisons, Explosives, and other special sources of danger to life or limb, Chairman, Rudolph Herng.

No more Fortunes in Pills.—According to a Philadelphia druggist, within the past three or four years the price of patent medicines has steadily declined, and fortunes are not made so rapidly as formerly out of pills and bitters. This cutting in rates began in Philadelphia, and has gradually extended all over the country. On some medicines the cut was as high as fifty per cent., and the reduction on all patent medicines will average over twenty-five per cent. Formerly a good patent medicine that was properly handled and liberally advertised would make a fortune for its proprietor in a few years. Remedies warranted to cure all the ills that flesh is heir to, and greedily purchased by a credulous public, sold readily at retail at one dollar per bottle and cost little to manufacture. They can now be bought for fifty cents, and the bottom price has not yet been reached. There is no longer any money in patent medicines, either for the druggists or the manufacturers. Prices have been cut so that the margin of profit hardly pays dealers for handling them, and the proprietors complain that the reduction has affected their business also. They claim that their medicines cost to manufacture and put on the market nearly what they are obliged to sell for to the jobbers. There has been a great revolution in the patent medicine business, and no one can tell where it will end.

New York State Board of Health.—This board held a meeting recently at Rochester, Drs. E. M. Moore, J. Savage Delavan, George W. Cooke, Woolsey Johnson, William M. Smith, Alfred Mercer, and A. L. Carroll, the secretary, being present. A financial statement showed an unused balance of $6,750 to the board's credit, an appropriation of $3,000 to carry out the law for the prevention of the adulteration of beer and similar liquors, and an appropriation of $10,000 for the administration of the law to prevent the adulteration of food and drugs, and the use of explosive oils. It was announced that the collection of samples of ales and beers for analysis by the board's chemist had begun. Dr. William Manlius Smith, of the quarantine committee, reported, calling attention to the chances for infection in importing rags. The health officer of the port of New York was directed to make such rules as seemed proper in the emergency, and the board recommended the Federal Government to resume the regulation of such importation. The administration of the law preventing the adulteration of food and drugs was referred to the sanitary committee with power to act. It was recommended that Professors S. A. Lattimore, of Rochester, Willis G. Tucker, of Albany, and E. C. Caldwell, of Ithaca, chemists, be employed as occasion required.

University of Vermont.—Dr. L. M. Bingham, of Burlington, Vt., has been recently appointed Professor of General Surgery in the Medical Department of the University of Vermont.

Mr. Hart Criticised.—The London correspondent of the *Philadelphia Medical Times*, August 8, 1885, expresses his decided dissatisfaction with the behavior of Mr. Ernest Hart, in his double position of editor of the *British Medical Journal*, and Liberal candidate for Parliament. He writes: "They seem to have made up their minds about the Contagious Diseases Acts at the East End. The Mile-End electors have not only made up their own minds, but they have even changed the mind of Mr. Ernest Hart, who pledged himself to vote for the unconditional repeal of the obnoxious measure. For the better understanding of the Contagious Diseases Acts, it may be said briefly that the Contagious Diseases (Human) Act refers to the public women of garrison-towns, who are by its machinery largely prevented from spreading disease by their trading in their persons. Of the good which the Acts have accomplished there is no question, and, next to vaccination, the profession is most solid on the Contagious Diseases Acts. Yet, at the imperative mandate of the radical riff-raff of Mile-End, this prominent member of the medical profession deserts his colors, and goes over to the enemy."

Plymouth's Latest Epidemic.—The people of Plymouth, Kingston, and the west side of the river are becoming alarmed over the prevalence of an epidemic of bloody dysentery, which is just now making itself felt. At Plymouth it is particularly bad, and is very virulent and fatal in its results. It is estimated that in Plymouth alone over one hundred persons are lying sick, and several deaths have occurred within the last week from this disease, and many others are in a critical condition. In Plymouth it is said to attack many who are just recovering from the typhoid fever, and in their weakened condition they fall easy victims. It is supposed to be caused by drinking the river-water, which is now largely used throughout the valley. The relatives of those who fell victims to the Plymouth epidemic are making preparations to commence suit against the water company for damages. The truth of the above has been denied.

The State Board of Medical Examiners of Virginia will meet at the Alleghany Springs (Virginia) on Wednesday, September 16, 1885, at 10 o'clock A.M., for the examination of candidates for the practice of medicine in that State, and for the transaction of such other business as may be brought before it.

Death of Dr. J. Savage Delavan, of Albany.—Dr. J. Savage Delavan, of Albany, a member of the State Board of Health, and one of the owners of the Delavan House, was drowned in Tupper's Lake, in the Adirondacks, on August 7th. Dr. Delavan was a graduate of the Albany Medical College, pursued special studies in Paris, and afterward became a homœopath. During the war he served with distinction as Assistant Surgeon of the First Connecticut Artillery, and was one of the first pension examining surgeons appointed by the Government. While a resident of Geneva, Switzerland, between 1872 and 1876, he was for a year United States Vice-consul. On the organization of the State Board of Health in 1880, Dr. Delavan became a member, being one of the three commissioners appointed by the Governor. In 1884, upon the expiration of his term, he was reappointed.

The Owens College Professorship of Anatomy.—The competition for the Professorship of Anatomy in the Owens College promises to be an animated one, several candidates of considerable reputation being in the field. Apart from local aspirants to the post, the principal competitor is Dr. W. P. Mears, who is at present in possession of the Chair of Anatomy in Durham University School of Medicine, with which his connection has lasted for over seven years. The value of the professorship at Owens is £700, but as the office of Dean of the Medical School would probably be associated with it, the annual income of the holder would be increased by £150.

Histohæmatin.—This is the name given by Dr. MacMunn to a class of pigments, or modifications of the same pigments, which are widely distributed in the animal kingdom, and to which myohæmatin belongs. The histohæmatins are respiratory pigments, as can be proved by oxidizing and reducing them in the solid organs. Their bands occupy almost the same place as those of myohæmatin. In the supra-renals of man, cat, and some other animals, the medulla gives the spectrum of hæmochromogen, while the cortex shows that of histohæmatin. Hæmochromogen in a vertebrate body is probably excretory, and must be so regarded here, hence the function of the adrenals must be (at least in a part) to metamorphose effete hæmoglobin or hæmatin into hæmochromogen. An active metabolic process takes place in the adrenals, and Dr. MacMunn concludes that they have a large share in the downward metamorphosis of effete coloring matter, and that his observations will help to throw some light on Addison's disease.

A New Constituent of the Blood.—Mr. L. C. Wooldridge describes, in the "Proceedings of the Royal Society," his method of obtaining "a new constituent of the blood" which he has lately discovered, and dwells upon its physiological import. The plasma of the blood of a peptonized dog, having been completely freed from all corpuscular elements by means of the centrifuge, is cooled down to zero, when the plasma rapidly becomes turbid, and a decided flocculent precipitate is formed. This is the body which gives rise to the fibrin ferment, and if examined microscopically the precipitate is found to consist of a number of minute transparent bodies, nearly circular in shape, but much smaller than the red corpuscle, and having a great tendency to run together into granular masses. These peculiar bodies may, perhaps, explain the granules, blood-plates, and hæmatoblasts of Osler, Bizzozero, and Hayem.

Death of Milne-Edwards.—Henry Milne-Edwards died at Paris on July 29th. He was born at Bruges in 1800, and studied medicine at Paris. He then devoted himself to natural history, and in 1838 succeeded Cuvier in the Academy of Sciences, and from 1841 he was Professor at the Jardin des Plantes, eventually taking the place of Geoffroy St. Hilaire. He resigned the chair of physiology in 1876, when his son Alphonse was appointed to it. Milne-Edwards was President of the French Scientific Association. The eminent professor was also Grand Officer of the Legion of Honor. His services to science are well known. The "Manual of Zoölogy" is probably the best known of his works in this country, but his most important contributions to scientific literature are contained in the twelve volumes of his "Leçons sur la Physiologie et l'Anatomie Comparée de l'Homme et des Animaux" (1857–1877). He was of English parentage.

The Pall Mall Gazette Endorsed.—The Committee consisting of the Archbishop of Canterbury, Cardinal Manning, the Bishop of London, Mr. Samuel Morley, M.P., and Mr. R. T. Reid, Q.C., M.P., who have undertaken the investigation of the truth of the statements recently published in the *Pall Mall Gazette* on the subject of the treatment of young girls, has concluded its sittings. They report that, after carefully sifting the evidence of witnesses and the materials before them, and without guaranteeing the accuracy of every particular, they are satisfied that, taken as a whole, the statements in the *Pall Mall Gazette* on this question are substantially true.

The Berlin University Institute of Public Medicine is about to be removed to the newly-built morgue. A wing of this building is to be furnished with offices, post-mortem rooms, laboratories, and two lecture-rooms. The Director is Professor Loman, who has held the post since 1864. He is also the town physician and forensic physician of Berlin. His predecessor was Joh. Ludw. Caspar, the well-known medical jurist, who founded the Berlin Institute of Public Medicine.

A Bust of Dr. De Mussy.—The Société Médicale des Hôpitaux has opened a subscription toward providing a bust of Dr. Noël Gueneau de Mussy, recently deceased, which is to be placed in the Hôtel Dieu, to which hospital he had been attached for many years.

A Physician Honored.—Dr. Vintras, Senior Physician of the French Hospital, London, has been appointed an Officer of the Legion of Honor.

A Scientific Centenarian.—The anniversary of M. Chevreul's birthday was celebrated on August 5th. On July 31st he had reached his one hundredth year.

What is Said of the Prospects of the International Medical Congress.—The leading medical journals both at home and abroad continue to speak in unequivocal terms of the deplorable results following the rash action of the new Committee at Chicago. *The New Orleans Medical and Surgical Journal* for August, 1885, says: "Already it is painfully evident that it is simply impossible to organize the American meeting of the International Medical Congress upon the plan adopted by the Chicago committee. Truly, we stand to-day a divided household, and unless some reconciliation can be effected, the failure of the Congress is inevitable. The present situation is deplorable beyond expression. A mighty responsibility rests on the present Committee on Organization. The members must realize the impossibility of organizing the Congress in further pursuance of the policy recently adopted. For the sake of harmony, through which alone the Congress can succeed and the profession escape a national disgrace, the Committee should make concessions to the gentlemen who feel aggrieved by their action; and such concessions to those who have resigned, as well as those who have been displaced, should meet only friendly responses and pledges of harmonious co-operation. We favor the organization of a national committee of peace-makers, composed of representatives from the States and Territories, to be appointed by the presidents of State and Territorial societies; from the District of Columbia, to be appointed by the president of the District society; and from the Army, Navy, and Marine Hospital Service, to be appointed by the ranking medical officer of each service. It is contemplated that a committee, constituted as above suggested, would be very potent in reconciling the differences now existing between the Committee of Arrangements, on the one part, and, on the other, the gentlemen who have been displaced and those who have voluntarily resigned all connection with the organization as now proposed. This committee failing in its purpose, we suggest that it is better to appeal the matter, as it now stands, to the American Medical Association for final adjudication."

The Medical Press, July 29, 1885, writes: "There is something very ludicrous in the attitude of the committee appointed by the American Medical Association, and which on its own authority alone presumed to undo the work already accomplished by the committee specially appointed by the Congress at Copenhagen. The former self-constituted body has deposed the well-known and respected physicians elected by the latter to preside in the various sections, many of whose names are of world-wide renown, and replaced them by a long string of non-entities, scarcely one of whom has ever been heard of outside the village in which he gains a living. The few celebrated physicians who were graciously permitted to retain official posts have naturally and properly shown their disgust by declining to be associated with the strangely mixed representatives of American medical science who are elevated into notoriety by the action of the Association ring; and things are now at such a pass that even the home journals are reckoning up the meeting as certain to be a miserable failure. The more sensible organs, however, are tendering the malcontents a piece of advice which they will do well to act upon; namely, that at their next meeting they should quietly determine their official existence, and resign the organization of the Congress to men of standing in the profession, and who will be able to command confidence and respect on this side the Atlantic. Unless some definite action of this kind is speedily taken, it is a moral certainty that the Congress, if persisted in, will lose every atom of its international character; for no one is going to contribute papers, or be at the expense of reading them to an assembly of mutual admirationists whose meddlesome conceit is scarcely equalled by their obscurity in the world of medicine. We have still, however, sufficient faith in the good sense of our American *confrères* as a whole, to feel assured that the little band of nobodies will speedily be sent to the rightabout, and the direction of the arrangements reassumed by the men who ought never to have resigned the trust reposed in them."

From an editorial in *The Lancet*, August 1, 1885, we quote the following: "We regret to have to inform our readers, that the ill-feeling which has been excited in the United States by the action of the committees appointed to carry out the preliminary arrangements are such as to imperil not only the success of the Congress in 1887, but the very existence of the Congress itself. . . . We cannot discuss the merits of this far from edifying quarrel, but we are too greatly interested in the International Medical Congress not to raise our voice in protest against a state of matters which is both a professional scandal and a serious peril to the continued existence of the Congress. Hitherto it has been considered binding upon all participating in the Congress that medical politics shall be entirely excluded from all its proceedings. But apart from that, we must impress upon our American friends the simple consideration that unless the whole profession in the United States combine cordially in the work of the Congress the meeting in Washington is foredoomed to failure. Party spirit is so alien to the whole spirit of the International Congress, that a large proportion of those who have previously joined in the meetings would certainly, and with justice, refuse to visit the United States to be the guests of a faction. But we have too high an opinion of our Transatlantic friends to believe that this unseemly quarrel, which is disgracing them throughout Europe, will be allowed to continue. We trust that moderating influences will be brought to bear upon both parties, and that, forgetting the past and their own personal predilections, they will cordially unite to promote the success of the meeting in 1887. If, however, the breach now formed is allowed to widen and deepen, it will be the duty of the officers of the Congress in Copenhagen to seek at once an invitation from some country in which the medical profession will not find it impossible to combine for international purposes."

Dr. Leroy M. Bingham, of Burlington, Vt., has been appointed Professor of Surgery in the University of Vermont, as a successor to Dr. J. L. Little, deceased.

Canine Excrements and Peptones.—The *Monthly Journal of Sciences* states, on the authority of a well-informed French contemporary, that the excrements of dogs are now collected in Paris and worked up into peptones and powdered extracts of meat.

Dr. W. W. Jaggard has been elected Professor of Obstetrics in the Chicago Medical College.

Dr. Tilt and Dr. Heywood Smith have been elected Honorary Corresponding Fellows of the Gynecological Society of Boston, U. S. A.

The British General Medical Council a Failure.—Dr. Fothergill writes, in the *Philadelphia Medical Times* of August 8, 1885, that the General Medical Council is a dead failure. Consisting of the representatives of the medical corporations, with a sprinkling of members chosen by the crown, it has disappointed every hope entertained of it, and falsified every prediction of its utility. It is hopeless. It does not even undertake the labor of prosecuting unqualified practitioners, leaving this part of its duty to anyone who will undertake it. The medical corporations do not represent any interests but their own, and no good can come or be expected from them. It is notorious that the much-talked-of Medical Bill has been thwarted by the persistent opposition of the threatened corporations.

The Prize Committee of the Medical Society of the State of New York.—For the information of all interested, the Prize Essay Committee of the Medical Society of the State of New York desires to state that the Society offers a prize of $100, payable out of the Merritt H. Cash Prize Fund, for the best original essay on any medical or surgical subject. The conditions are: That the competitors shall reside in the State of New York; that all essays offered shall be either printed or type-written; that each essay shall be designated by a motto on the title page; that in a sealed envelope attached to the essay shall be placed the name of the writer and the corresponding motto; and that all essays shall be sent to W. W. Potter, Buffalo, N. Y., on or before January 1, 1886.

The Cholera Still Active.—From Marseilles comes the report that at a tumultuous meeting of the municipal authorities there, on August 11th, the sum of one hundred thousand francs was appropriated for sanitary purposes. The cholera panic increases daily. The average of departures from Marseilles by railway alone has already increased 2,000 per day. As an instance of the laxness with which the Marseilles sanitary authorities perform their duties, the case of the captain of an English vessel lying in the port is mentioned. The captain's daughter died of cholera aboard the ship. He at once notified the authorities and requested a disinfection of the vessel. At the time of this report thirty hours had elapsed since the girl's death and yet no official action had been taken concerning the event by the Marseilles authorities. In Spain the cholera mostly prevails in low-lying, damp regions.

Criminal Carelessness.—Some repairs were recently made in the plumbing at Bellevue Hospital. Through the carelessness of one of the workmen, a pipe connecting directly with the sewer was left open in the room of one of the house-surgeons. The latter, unaware of the fact, slept in the room several nights, and was soon stricken down with typhoid fever. He now lies in a critical condition. We think the hospital authorities should institute proceedings against those having the repairs in charge.

Cremation Increasing in Popularity.—The cremation societies are increasing in number, and some of those which are open have their facilities pretty well taxed. The crematory at Lancaster, Penn., is in use very frequently, and there are a large number of bodies lying in vaults awaiting the completion of the one near New York. A society has just been formed at Worcester, Mass., and a bill authorizing the formation of corporations for the purpose of disposing of the dead in this way has passed the Legislature of that State. The recent decision in England that cremation was not illegal has had the effect of creating a number of societies, and one cremation at least has taken place. It certainly appears to be true that this practice is rapidly on the increase, both here and abroad. At a recent sitting of the Corporation of Hamburg, Germany, a motion for permitting cremation in the State of Hamburg, introduced by Dr. Grieschen, was carried unanimously. It is believed that the Senate of the State will give its consent to this resolution.

Reviews and Notices.

Poisons: Their Effects and Detection. A Manual for the Use of Analytical Chemists and Experts. With an Introductory Essay on the Growth of Modern Toxicology. By Alexander Wynter Blyth, M.R.C.S., F.C.S., etc. With Tables and Illustrations. Volume I. New York: William Wood & Co. 1885. Wood's Library of Standard Medical Authors.

The present work, we are informed in the preface, completes an entirely rewritten and greatly enlarged Second Edition of the author's "Practical Chemistry." It constitutes a companion volume to the author's work on Foods. Together they form a noble monument to Mr. Blyth's labor and erudition.

A good many works upon Toxicology have appeared of late years and any new volume must have some especial merit in order to enable it to claim a place among standard works. The present one promises to be the most complete and satisfactory work of its kind which we have yet seen. It should be understood, however, that the author limits his work to poisons alone, and does not take up questions of jurisprudence in connection therewith. The volume before us begins with an extremely interesting chapter on the history of poisons, or rather of the history of the use of poisons, and the gradual development of the science of Toxicology. Part II. takes up the subjects of the definition and classification of poisons, statistics of deaths by poison, and the methods of searching and testing for poisons. The special descriptions begin with Part III., in which the poisonous acids and alkalies are described. Part IV. discusses the volatile poisons, and Part V. concludes the book with descriptions of the alkaloids and other poisonous vegetable principles.

Each particular article is gone over exhaustively, and information is brought down to date. We believe that the general practitioner will find the present work a most valuable one both for reading and reference in the not infrequent emergencies when a thorough toxicological knowledge is needed.

An Excellent Face-Wash consists of a one per cent. solution of boric acid in rose-water, with five per cent. of honey added.

Died of an overdose of reconstruction! A good epitaph for a dead Congress.—*Louisville Medical News.*

Reports of Societies.

THE AMERICAN OPHTHALMOLOGICAL SOCIETY.

Twenty-first Annual Session, held at the Pequot House, New London, Conn., Wednesday and Thursday, July 15 and 16, 1885.

DR. WILLIAM F. NORRIS, OF PHILADELPHIA, PRESIDENT, IN THE CHAIR.

(Continued from p. 167.)

WEDNESDAY, JULY 15TH—FIRST DAY—AFTERNOON SESSION.

DR. S. D. RISLEY, of Philadelphia, read a paper on

HYPERMETROPIC REFRACTION PASSING INTO MYOPIC REFRACTION.

The Doctor had on previous occasions called attention to five cases of a similar kind, and the object of his paper to-day was simply to report six additional cases seen within the past year.

DR. W. S. DENNETT, of New York, made a few remarks on the importance of the examination of spectacles. He exhibited a series of drawings showing the effect of different kinds of lenses on straight lines.

He also exhibited an electric light ophthalmoscope, a description of which has been printed in THE MEDICAL RECORD.

DR. LUCIEN HOWE, of Buffalo, N. Y., exhibited

AN ARRANGEMENT FOR THE DEMONSTRATION OF REFRACTION AND ACCOMMODATION.

This consists of two bands of thin metals bent in such a manner as to represent the outlines of a double convex lens, and passing through it two jointed rods representing the rays of light ordinarily figured as passing through such a lens and joining at its focus. The flexible bands were attached to each other above and below, so that by approaching or separating the sides they could be made to show less or greater convexity. The rods representing the rays of light were jointed near the centre in such a way that while the two halves could be placed in such a direction as to show the light as entering parallel to the axis of the lens, the other two portions could be bent to a point to show the convergence of rays at the focus. By alteration in the position of these rods and also in the forms of the bands representing the lens, all the different variations of the laws of refraction and the changes in accommodation can be demonstrated to a class.

DR. E. DYER, of Newport, R. I., demonstrated a perimeter which he had described at the last meeting of the Society.

A paper on

TWO CASES OF UNILATERAL TEMPORAL HEMIANOPIA

was read by DR. C. S. BULL, of New York.

The first case was that of a man aged sixty-six, first seen in 1884. In 1882 he received an injury which rendered him unconscious. When he regained consciousness found that he was blind in the right eye. In 1883 he noticed a central obscuration of vision in the left eye. There was no syphilis, no disease of the heart, and no indication of Bright's disease. He had never used alcohol to excess, but smoked and chewed tobacco in large amounts. There was an irregular central scotoma. The media were transparent and the iris normal. Both optic disks were of a dirty-white color, and in both there was a deep excavation with pulsating veins, and in the left eye there was a large retinal hemorrhage. The tension was normal.

The second case occurred in a man aged sixty. He had been knocked down by a horse, receiving a depressed fracture of the frontal bone above the left eye. The patient was unconscious or delirious for four weeks following the accident. When he regained consciousness he found that the left eye was blind. Examination showed that in the left eye there was somewhat irregular temporal hemianopsia. This may have resulted from fracture of the superior orbital plate, with injury to the fibres of the optic nerve going to the temporal half of the retina.

DR. H. DERBY, of Boston, read a paper on

TWO CASES OF PENETRATION OF THE EYEBALL WITH SCISSORS, IN THE OPERATION FOR STRABISMUS.

The first case was that of a young man on whom an operation for strabismus had been attempted. The surgeon inadvertently picked up a pair of sharp-pointed scissors. The point of the scissors suddenly penetrated the eyeball, and a portion of vitreous equal in size to a cherry-stone escaped. The operation was abandoned, and Dr. Derby was called to see the case. The eye was bandaged and the patient put to bed. Several attacks of inflammation supervened, but the patient was discharged on the forty-first day with V. = $\frac{1}{10}$.

In the second case the scissors also entered the sclerotic, but after a somewhat tedious convalescence the wound was found closed on the twenty-first day with vision as good as before the operation.

DR. KNAPP stated that he had done three thousand squint operations, and in three cases he had punctured the sclerotic. He, however, completed the division of the muscle, and the patients recovered as readily as from an uncomplicated operation.

DR. MITTENDORF stated that he had been present at a strabismus operation where the sclera was opened. He advised the surgeon to complete the operation. This was done and the wound had healed in four or five days. He thought that, in case the accident happened, the division of the muscle should be completed.

DR. E. WILLIAMS, of Cincinnati, reported a case in which he had punctured the eye. The patient recovered without difficulty.

DR. E. E. HOLT, of Portland, Me., read a paper on

STRABISMUS; ITS CORRECTION WHEN EXCESSIVE AND IN HIGH DEGREES OF AMBLYOPIA.

The writer had employed advancement of the weakened attenuated muscle in connection with tenotomy in certain cases of squint, and after tenotomy alone had failed to correct the deviation. He also exhibited an apparatus he had devised for showing the associated and accommodative movements of the eyes and the effects of tenotomy and advancement of the muscle in correcting squint.

DR. KIPP at one time employed advancement, but he had given it up because it was difficult to graduate the result.

A paper on

THE TREATMENT OF STRABISMUS INTERNUS

was read by DR. W. W. SEELY, of Cincinnati, in which the author said that each year with its added experience had strengthened the conviction that early operations (up to the tenth or fifteenth year) are questionable and possibly should be entirely abandoned. He combated the idea that crossed-eyes never become straight without an operation. Nothing is better established than the relation between ametropia and strabismus; and all recognize the necessity for glasses to prevent the recurrence of the squint after tenotomy. Everyone knows that it is possible to correct the squint by setting aside the ametropia by means of glasses.

The author's early conviction that something should be left to time and glasses has long since grown into an absolute law of action, for he had become thoroughly persuaded that immediate perfection meant later in life insufficiency or even divergence. Operative procedures should not be the first consideration, but should be looked

on as an adjuvant to be resorted to later on if necessary. He summed up as follows: 1. That, with our present light, routine operative interference is wrong. 2. That to thoroughly correct the deviation in young children by operative interference is extremely liable to subject them in after life to insufficiency or external squint. 3. That a later period of life if anything favors better results from operative interference.

Dr. Knapp thought advancement a dangerous operation. He had always been able to correct the deviation by two or three tenotomies, and, if necessary, stitching the eye to the commissure.

Dr. Theobald, of Baltimore, endorsed Dr. Knapp's views in reference to advancement. He was surprised at the conclusions of Dr. Seely. Squint operations in his hands had been very satisfactory. If postponed, they are likely to prove unsatisfactory on account of the amblyopia which is liable to develop.

Dr. O. F. Wadsworth had studied the subject for a long time, and had convinced himself that amblyopia from squint did not occur. The ability of the patient to use the vision which he has does seem to be lost by a continuance of the squint, but it may be recovered by practice. If the examination of vision was carefully made, he was certain that it would be found that the vision was not improved after the operation. It, however, is often difficult to get the full amount of vision which a squinting eye possesses.

Dr. R. H. Derby, of New York, read a paper on

ECTROPION OF BOTH LIDS—BLEPHAROPLASTY BY THE ITALIAN METHOD.

The displacement of the lids was the result of cicatricial tissue from a severe and extensive burn of the face. The lids were loosened from these attachments and the new lids formed from flaps raised from the arm. The arm was bound to the head with water-glass plaster, and the pedicle was not divided until union had taken place. Photographs were exhibited showing the appearance of the patient before and after the operation.

Dr. Hasket Derby exhibited a box of trial lenses, made by Nachet, in which the following features were embodied: 1, The doubling of the prisms; 2, the distinguishing of the cylindrical lenses by coloring the positive settings black and the negative red; 3, the adaptation of the trial frames to receive the glasses without removal from the patient's head; 4, the removal of the handles from the prisms and cylindrics.

A paper on

PLASTIC OPERATIONS WITHOUT PEDICLES

was read by Dr. B. Joy Jeffries, of Boston.

The object of the paper was to make one or two suggestions which the author had not yet put in practice, but which he was ready to try when opportunity offered. He suggested the use of the prepuce from the circumcision of Jewish children for operations about the eyes. He also suggested that in plastic operations the desired result might be obtained without the use of a flap by employing carbolized-oil dressings to retard healing, for it is well known that some time after a plastic operation the transplanted tissue has almost entirely disappeared.

Adjourned until evening.

Wednesday, July 15th—First Day—Evening Session.

Dr. Harlan, of Philadelphia, reported

TWO CASES OF CONGENITAL PARESIS OF THE EXTERNAL RECTUS.

Dr. Harlan also exhibited and described Borck's sphero-cylindrical lenses.

THE REMOVAL OF A BIT OF STEEL FROM THE LENS WITH THE ELECTRO-MAGNET

was the title of a paper by Dr. J. L. Minor, of New York.

M. S—— was struck, one week before coming under observation, by a piece of steel. There was a small scar in the cornea, and vision was much reduced. There was clearly a piece of steel in the lens, which the doctor desired to remove at once. After consultation, it was thought advisable to await the development of some symptoms. The patient was, therefore, given atropine, and instructed to return if the eye gave any trouble. Some time later the eye became irritable. There was considerable ciliary injection. There was haziness, and the tension was increased. Cocaine was employed and iridectomy performed. The shank of a strabismus-hook was touched to an electro-magnet, thus making it a magnet. The extremity of the hook was then carried into the lens, and the piece of steel at once attached itself to it and was removed. Thirteen days later the eye had recovered from the operation. The lens has not yet been removed.

Dr. R. H. Derby, of New York, reported a case of

MALFORMATION OF THE UPPER LID.

In this case there was a fissure of the upper lid, from the angle of which a portion of skin projected in a peculiar manner.

REMOVAL OF EPITHELIOMA OF THE EYELID BY APPLICATIONS OF BENZOLE AND CALOMEL,

by Dr. A. Matthewson, of Brooklyn. O. D——, laborer, fifty years of age. was seen October 3, 1881, with tumor on the right lower lid. This first appeared as a warty growth three years previously. Of late it had been rapidly growing, and presented a raw granulation surface. Careful examination by an expert showed it to be undoubted epithelioma, It was treated by frequent dustings of calomel, after brushing the surface with benzole. The tumor entirely diappeared until a few months ago, when a granular spot appeared at one edge of the site of the former growth. This disappeared under a renewal of the same treatment.

Dr. H. S. Schell, of Philadelphia, read a paper on

LIPOMATOUS PTOSIS.

Under this head the speaker reported four cases of ptosis from excessive accumulation of fat in the upper lids. The condition occurred in young women between the ages of eighteen and twenty-five. The deformity was symmetrical, the weight of the lid causing it to cover one-half of the cornea. The excessive fat was removed through a horizontal incision. The smallest amount taken away was thirty-five grains; the largest, seventy-one grains. The levator regained power in from one to four weeks. In one case it was necessary to repeat the operation.

Dr. L. Webster Fox, of Philadelphia, reported some

CLINICAL OBSERVATIONS.

Case I.—*Congenital cataract in both eyes successfully operated on in a patient sixty years of age.*—H. H——, negress, aged sixty, presented herself at the Germantown Hospital, February 4, 1884. Congenital cataract of both eyes was found. The use of a four-grain solution of atropia produced no dilatation of the pupils. There was simply light-perception. Shortly afterward the right lens was removed, and the wound rapidly healed. At the end of eight days the patient could see, but could not name objects without touching them. The lens of the left eye was subsequently removed. The effect of the acquisition of sight after sixty years' blindness was carefully described by the doctor. The lenses when removed were found to be of a spheroidal shape. The optic nerve presented an oval outline.

Case II.—*Recovery of useful vision after eighteen years' blindness.*—R. L——, aged thirty-seven years, was injured in the left eye when three years of age. Two years subsequently sympathetic ophthalmia developed in the right eye, resulting in qualitative perception of light only. An iridectomy was done at the Germantown Hospital in June, 1884. The media were found to be clear. When admitted to daylight com-

plained of erythropsia to such an extent that dark glasses were ordered. This disappeared in the course of three months. A + 10 D. spherical glass was ordered for distant use, and a + 14 rendered near objects visible. Subsequent examination showed that better vision was obtained by a combination of spherical and cylindrical lenses.

He also related the history and treatment of five cases of retinitis pigmentosa by electricity (constant current). There was marked improvement, which, in one case, remained nine months after discontinuance of the treatment. Five cells are usually employed, the positive pole being placed over the closed eyelid, and the negative pole at the nape of the neck.

Dr. Lucien Howe, of Buffalo, N. Y., read a paper on

THE PULSATING VARIATIONS OF INTRA-OCULAR TENSION AS MEASURED BY THE MANOMETER.

In calling attention to the variations of intra-ocular tension some attention also was given to various forms of manometer, or instruments for its measurement. The earlier forms consisted simply in a U-shaped tube of glass connected by a flexible tube to a trocar. When the trocar was introduced into the anterior chamber of the eye the intra ocular pressure would tend to force the fluid through the tube and show the degree of pressure by a rise in the opposite column of the U-shaped tube. This was imperfect, for the reason that when the aqueous humor escaped from the eye it was at once in an abnormal condition. The double manometer described by Grasser and Holzke obviated this difficulty. In this, however, there was an imperfection in the trocar, which was rather complicated and liable to get out of order. An improvement was accordingly suggested in having a stopcock attached to a needle of the hypodermic syringe and this the writer found to serve the purpose much better than any other. The animal best adapted to this class of experiments is the cat, on account of the deep anterior chamber.

In the earlier experiments with the manometer, it was noticed that the intra-ocular tension varied with the heart's action. In addition to this the writer called attention to the fact that these variations in the pressure, as indicated by the manometer correspond to pulsations which can be seen with the ophthalmoscope in the vessels in the interior of the animal's eye. In other words, if the same thing holds in the human subject we must infer that when pulsation is seen in the interior of the eye there is also a variation of intra-ocular tension, although not enough to be detected by the touch or by an ordinary instrument. This connection between pulsation and pressure is a demonstration of the cause of venous pulse in the eye as explained by Donders. It was also observed that after the introduction of the needle there was at first considerable pulsation, but after a short time this ceased, the eye evidently adjusting itself to the unusual condition. The experiments referred to were made in the laboratory of Professor Zunt, of Berlin.

Dr. H. Knapp, of New York, reported nine successive cases in which the electro-magnet was used for the extraction of chips of iron from the interior of the eye. These cases were operated on during the past three and a half years. In two the chip of iron was located in the iris, in one for two days, causing inflammation, and in the other for seventeen years, remaining quiet until recently. Both were successfully removed without deterioration of the eye.

In the seven remaining cases the foreign body was in the vitreous, had produced cataract and could not be seen. In three cases the atttempt to extract them with the magnet failed and the eyes had to be enucleated. In four cases the chips of iron were brought forth at the first, second, or third introduction of the tip of the magnet. In all these four cases, the recovery was smooth. All four are still cataractous. In two the form, size, and tension of the globe is not changed and the perception of light is good over the whole field. In the two others the globe is slightly smaller and softer and the field of vision defective, corresponding to the wound made for the extraction of the foreign body. There was no irritation in any of the four eyes as long as they were under observation.

Dr. H. Knapp, of New York, also read a paper on

THE ACTUAL CAUTERY IN DESTRUCTIVE CORNEAL PROCESSES.

The Doctor cited a number of cases in which its use had been of service and considered it a valuable measure.

Dr. Howe had employed this measure in three cases and the corneal ulcer had been somewhat lessened.

Dr. E. Williams, of Cincinnati, had for the past fifteen years been in the habit of treating phlyctenular ulcers of the cornea by the application of pure carbolic acid and had found it to act admirably.

Dr. O. F. Wadsworth, had for several years been in the habit of using carbolic acid for ulcus cornea serpens and for sluggish, painful infiltrations of the cornea. In sluggish infiltration the application is preceded by scraping and in some cases the simple scraping had been sufficient. When the ulcus cornea serpens had been severe, he did not recall that it had entirely stopped the process. In a recent case in which the acid was applied at the beginning of the affection, three applications checked the disease.

Adjourned to Thursday morning.

Thursday, July 16th—Second Day—Morning Session.

Dr. W. F. Mittendorf, of New York, read a paper on

PNEUMOPHTHALMOS, OR AIR IN THE VITREOUS HUMOR.

The entrance of air into the interior of the eye will occur at times during an operation, as, for instance, a cataract extraction. In such cases the air may get into the anterior chamber, whence it can be removed with ease. It is, however, entirely different when air gets into the vitreous chamber. Fortunately this accident is of such rare occurrence that so far no description of it has been given. The writer had seen two cases of this kind within the last two years. Both occurred in connection with injuries caused by the entrance of foreign bodies into the interior of the eye. Such accidents are usually so serious that any complication of them becomes a matter of great interest. The first case was that of a young blacksmith who was wounded by a piece of iron penetrating the sclera and lodging in the vitreous humor. The foreign body, surrounded by a clot of blood, was found at the bottom of the eye. Behind the lens and a little above it three air-bubbles were seen by means of the ophthalmoscope. These appeared to be of the size of a small pea, the smallest about as large as a rape-seed. They closely resembled the air-bubble as seen under the microscope, their centres being bright and the outlines well defined and surrounded by a sharp black border. Their recognition was not difficult. The foreign body could not be removed with the magnet, and it was decided to allow it to remain. The eye was carefully bandaged and the day following it was found that the air-bubbles had united and located at the posterior pole of the lens, the patient having remained quietly on his back some time before the examination. While he was in the upright position the air began to rise slowly until it reached the upper part of the vitreous chamber. During this trip the bubble looked oval and decidedly pointed at its lower portion, resembling oil-globules as they are seen ascending in water. Forty-eight hours after the accident every trace of the air-bubbles had disappeared.

The second case reported was the result of a drilling accident. A pretty large piece of stone or iron had perforated the sclera at the lower and outer part of the

eye. In the semi-transparent vitreous an air-bubble of the size of a hemp-seed could be seen distinctly.

In order to determine the exact appearance of air in the vitreous, the writer experimented upon rabbits' eyes. Four of them had air introduced into the vitreous humor by means of a hypodermic syringe, and four were subjected to the introduction of oil, also by means of the hypodermic syringe. Nearly all these experiments were successful. The difference between the air- and the oil-bubble was so marked that they could be readily diagnosed by means of the ophthalmoscope. The latter were more highly refractive, heavier in appearance, and the contour decidedly darker than the air-bubbles, which were entirely colorless.

The conclusions reached by the author were as follows: 1. The entrance of air into the vitreous body can occur only after a part of the contents of the vitreous chamber has escaped. 2. It is favored by the entrance of a foreign body which makes a large, gaping, irregular wound of the sclera. 3. In order to allow air to enter the vitreous humor, this must either be quite fluid or its anatomical arrangement must have been disturbed by the entrance of a foreign body, or the air must have been attached to the foreign body and be thus carried with it into the eye. 4. The air in the vitreous humor appears like an air-bubble as seen under the microscope, it is more or less round, highly refractive in the centre, and has a sharply defined black outline. 5. Oil-globules in the vitreous present a similar appearance, but they look heavier, are not perfectly colorless, and their outlines are darker; they are also more glittering in the centre. 6. Air-bubbles will be completely absorbed within two or three days. Their presence is not a source of great danger to the eye. Oil-globules last longer, but they are likewise non-irritating.

Dr. Myles Standish, of Boston, reported

A CASE OF TUBERCLE OF THE IRIS.

The history was as follows: A girl, fourteen years of age, both of whose parents were living and had never presented any evidences of syphilitic or tuberculous disease. There was no suspicion of specific taint. During the past winter intense pain in the epigastrium and ascites had been noted. Acute hepatitis was the diagnosis reached by the family physician. No pulmonary lesion was detected.

The eye trouble had existed for four weeks when seen by the speaker. There had not been much pain or photophobia. The iris was attached by its pupillary margin to the capsule, and on it there was a growth, two millimetres in diameter, pink in color. This projected from the iris near its ciliary border.

In the course of a month the eye was enucleated on account of increase in size of the growth and the appearance of other growths.

The vitreous, retina, and choroid were found to be normal. The lens was somewhat opaque. The iris was very adherent to the capsule of the lens along its pupillary border and also beneath the entire area of the principal growth. The largest mass sprang from the surface of the iris near its ciliary border, and at its base was 2.5 mm. in diameter and it was 2 mm. in height. At the top its diameter was 4 mm. This was apparently due to the pressure of the growth against the cornea. There were three other growths, but none of them involved the ciliary body or even the ciliary border of the iris.

Under the microscope the evidences of tubercle were quite distinct, giant cells and bacilli tuberculosis being found.

Dr. Knapp had seen growths presenting exactly the same appearance which had disappeared under the use of specific treatment with mercury even where there was no evidence of syphilis. He had never felt warranted in making the diagnosis of tubercle in such cases, although the presence of the tubercle bacilli in this case would seem to confirm the diagnosis.

A CASE OF CONGENITAL COLOBOMA OF THE IRIS, CHOROID, ETC.,

was reported by Dr. C. J. Kipp, of Newark.

The patient was a woman, sixty-nine years of age. She was first seen four years ago. There was at that time no inflammatory symptoms, but a small triangular coloboma of the iris was found exactly in the vertical meridian. The tension was above normal. The patient had never seen with this eye, but it had never given pain. Four years later the patient was again seen, and the eye presented the signs of inflammatory glaucoma. The pain had prevented sleep for many weeks. The eye was enucleated and healed promptly. There was also found a large ectasia of the sclerotic, and over this the choroid and retina were wanting. The ectasia extended close to the optic papule. There was also a deep kettle-shaped excavation of the optic nerve.

A paper on

COLOBOMA OF THE CHOROID ON THE TEMPORAL SIDE

was read by Dr. S. D. Risley, of Philadelphia.

A young physician consulted Dr. Risley for asthenopia. There was a considerable degree of myopia in the left eye. In the right eye vision was much diminished, $\frac{20}{70}$. The ophthalmoscope showed a large hiatus in the choroid on the temporal side, the depth of which was 3 D. There had been no pain. The speaker thought that these cases were comparatively rare.

Dr. Mittendorf had seen several of these excavations in the outward direction. Where the coloboma was so deep he thought that it was probably a coloboma of the optic nerve-sheath with excavation of the nerve. A difference of 4 D. would indicate a greater defect than would correspond to absence of choroid and retina alone.

SEROUS EFFUSION IN THE VITREOUS DUE TO MALARIA.

In a paper on this subject Dr. W. W. Seely, of Cincinnati, considered the occurrence of this complication not infrequent and he reported one case of this affection.

Dr. William F. Norris read a paper entitled

GRAY DEGENERATION OF THE OPTIC NERVE WITH ABNORMAL PATELLAR REFLEX.

After an elaborate review of the literature of the subject the speaker gave the results of his observations in cases where the patellar reflex was increased or diminished. He described three cases of gray degeneration associated with tabes dorsalis which had come under his observation. While he did not hold that this symptom indicated beginning tabes dorsalis, yet it was a danger-signal calling for rest of the brain and cord with attention to improvement of the general condition.

Dr. O. F. Wadsworth, of Boston, reported

A CASE OF DOUBLE OPTIC NEURITIS AND OPHTHALMOPLEGIA FROM LEAD-POISONING COMPLICATED WITH TYPHOID FEVER.

A boy nine years of age had suffered from obscure febrile symptoms for several weeks and movements of the left eye had been observed to be imperfect. When first seen by Dr. Wadsworth there was pronounced optic neuritis in both eyes. The rest of the fundus normal. Vision was much diminished. No lateral movements of left eye could be made and movement downward was impaired. The outward movement of right eye was defective. The probable diagnosis was tumor in the region of the pons. The movements of the eyes became still more impaired and vision sank. The boy developed pretty distinct symptoms of typhoid fever. The spleen and liver were both enlarged. Lead was found in the urine and the diagnosis of tumor was then abandoned. The treatment was with iodide of potassium. The general condition gradually improved. The neuritis passed into atrophy, leaving too little vision to count fingers. The move-

ments of the eyes were completely restored and the lead disappeared from the urine. The cause of the lead-poisoning was found to be the presence of a piece of lead-pipe in the cistern from which the drinking-water was obtained.

Dr. Joseph A. Andrews, of New York, read a paper on

OLIVE OIL AS A MENSTRUUM FOR DISSOLVING COCAINE FOR APPLICATION TO THE EYE.

In addition to the occasional benefit from the use of oil, dropped into the eye in recent abrasions from burns and in other painful affections of the cornea in which atropia is indicated, cocaine may likewise be serviceable. The plan of dissolving the cocaine in oil seems to insure a longer contact of the remedy and a smaller quantity is required to effect anæsthesia, two qualities of especial advantage in operations on the eye.

Neither the salt of cocaine nor of atropia is soluble in olive oil, but the alkaloid of both dissolves readily in the menstruum without the addition of an acid, it being only necessary to expose the solution for a few minutes to a gentle heat in a water-bath. Castor oil is not a desirable menstruum on account of its irritating qualities, and the oleate of cocaine, for the same reason, is still more objectionable as an application to the eye.

A CASE IN WHICH ENUCLEATION OF THE EYE FOR GLAUCOMA HAD PRECIPITATED GLAUCOMA IN THE OTHER EYE

was reported by Dr. David Webster, of New York. The patient was a man aged fifty-four, the subject of glaucoma absolutum. He complained of periodical obscurations of vision in the good eye. V. = $\frac{20}{15}$ and there was no limitation in the visual field. As he was of dissipated habits he was advised to live properly. A week or two later returned, stating that he had had a worse attack. There was an excavation of the nerve in the good eye detected. The glaucomatous eye was now removed. Two days later acute glaucoma appeared. An iridectomy was performed and he recovered in a week or two with V. = $\frac{20}{40}$, with no cupping of the disk and no limitation of the field. This was the only case he knew of in which enucleation had precipitated an attack of acute glaucoma in an eye already predisposed to it. He had, however, reported cases in which iridectomy had produced the same effect.

Dr. E. Williams, of Cincinnati, reported

TWO CASES OF QUININE AMAUROSIS.

In the first case a man took about one ounce in the course of four days. This produced total blindness and deafness, but in six weeks he could see as well as ever; the hearing had never completly returned, although the quinine was taken eight years ago. The field of vision was concentrically contracted in both eyes. The optic disks were very white, the calibre of the arteries and veins was reduced, and the smaller capillaries could not be seen.

The second case was that of a boy, aged fourteen, who had received large doses of quinine, the exact amount not being known. He was totally blind for four days. When examined, the sight was much diminished, and the atrophy of the optic disks was extreme and there was great contraction of the field of vision.

A MEANS OF MEASUREMENT OF THE AMOUNT OF ANÆSTHESIA FROM COCAINE.

Dr. Lucien Howe, of Buffalo, exhibited the drawing of a kymograph which he had used for this purpose. The use of the instrument was based on the fact that irritation of a sensory nerve is followed by a rise of blood-pressure. The instrument is connected with an artery and the conjunctiva is irritated. Cocaine may then be applied and the results on the blood-pressure compared.

Dr. Harlan, of Philadelphia, presented a modified ophthalmoscope which had been devised by Dr. Jackson, of Philadelphia. In it the lenses moved vertically instead of circularly.

Dr. Dennett, of New York, exhibited an arrangement for using Stokes' lens for measuring astigmatism, and to avoid the inconvenience of constantly removing the frame from the patient's nose. The lens was mounted on a stand and could thus be placed in front of the patient.

The Society then went into executive session.

The officers for the following year are:

President—Dr. Wm. F. Norris, of Philadelphia.

Vice-President—Dr. Hasket Derby, of Boston.

Secretary and Treasurer—Dr. O. F. Wadsworth, of Boston.

Corresponding Secretary—Dr. J. S. Prout, of Brooklyn.

New members were elected as follows: Drs. Chas. A. Oliver, of Philadelphia; Edward Jackson, of Philadelphia; B. Alexander Randall, of Philadelphia; D. Pope Walker, of New York; William O. Moore, of New York; Frank G. Capron, of Providence; S. M. Burnett, of Washington; Wm. T. Bacon, of Hartford.

The next meeting will be held at New London, the third Wednesday in July, 1886.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

CLOSE OF THE ACADEMICAL YEAR—CHANGES IN THE CURRICULUM—THE TEACHING OF MATERIA MEDICA—PROFESSORS AND TEXT-BOOKS—MEDICAL CANDIDATES FOR PARLIAMENT—MR. WHARTON JONES AND THE PHYSIOLOGISTS.

London, July 25, 1885.

The academical year now closing has witnessed great changes in medical education in London. The entire curriculum has virtually been revolutionized by the establishment of the Conjoint Examining Board for England and Wales. The first step toward sessional examinations has been taken by the establishment of what has long been talked of, viz., a compulsory examination for students at the end of the first year. The first summer examinations under the new scheme are now being held. The wisdom of the new scheme is at any rate open to question, as regards one of the summer subjects, Materia Medica. This subject—using the word in its widest sense—has been cut in two. The therapeutical division of the subject has been relegated to the final examination, leaving the pharmaceutical, chemical, and botanical parts to be digested as best they may A fraction of the paper is devoted to the physiological action of drugs, but the actions and uses of medicines are regarded as being beyond the comprehension of first year's students, who are expected to enliven as best they can the hours devoted literally to the study of the dry leaves of the subject. I am not exaggerating. At the College of Physicians a question has actually been asked about the "Leaves" of the Pharmacopœia.

Under the new arrangement the London teachers of Materia Medica are somewhat in a quandary. One of them, Dr. F. T. Roberts, has boldly announced his intention of devoting his lectures entirely to therapeutics, and has issued a small text-book, devoted entirely to the other divisions of the subject. It is accurate, but dry as the specimens which it describes. Such a book may sell because Dr. Roberts is an examiner, but cannot enhance his reputation. Moreover, there cannot have been a real want for such a book, as Dr. Isambord Owen's little work, issued a year before, covers the same ground, and is more readable.

Another gentleman, who is also an examiner—Dr. Lauder Brunton—meets the difficulty by including all pharmaceutical, botanical, and chemical details in his recently issued book, and protesting in his preface against the importance attached to their study. He quotes with approval the *reductio ad absurdum* suggested by

the late Professor Sharpey—that we might as well require a knowledge of the whole art of cutlery before setting a student to dissect. Dr. Brunton follows this up by remarking that we now oblige a student to learn the physiological action of drugs, a subject about which little was known until recently, and that to require all this *in addition*, is to treat them as Pharaoh treated the Israelites. Coming from an examiner who sets such questions as those now given, this remark is, to say the least, rather unfortunate.

An examination of Dr. Brunton's elaborate work suggests some reflections not wholly favorable. Nearly half of it is devoted to what the author terms "General Pharmacology and Therapeutics," in which the actions of drugs on the various tissues and organs of the body are treated of at great length, and, it must be added, with great learning and ability. The multiplicity of details given throughout the work is bewildering; so are the numerous references to German authorities. The practical doctor who refers to its pages will often, however, be disappointed. He will remember it as a treatise in which nearly a page is devoted to an explanation of the probable mode of action of arsenic in phthisis, but in which, although arsenic is mentioned as useful in diseases of the skin, no one cutaneous affection is named for which it may be given; as one in which the use of sulphur ointment as a remedy for scabies is given, but no details as to how to use it; as one in which the old error of describing citrate of lithia as amorphous and deliquescent is perpetuated; and as one in which it is suggested that iodoform may be employed as a vapor. There are numerous references, but those to British writers are very few and far between, and not always given where they should be in justice. Koch's remarks as to the comparative inertness of carbolized oil are given, but the much earlier original observations of Dr. Sansom are ignored. Similarly, the method of giving aconite in hourly drop doses is incorrectly ascribed to Dr. Ringer, instead of to Dr. Prosser James, who introduced it to the profession before Dr. Ringer was in practice. Dr. John Harley's observations and experiments are not even mentioned under conium, and Dr. Garrod's observations on lithia salts are completely passed over. On the other hand, the book is burdened with the details of the effects of some drugs on birds and mammals, and no inconsiderable amount of toxicology is introduced. Such is our last work on Materia Medica—a book more for the physiologist and the laboratory than for the busy practitioner in daily practice. Much of our vaunted modern medical teaching has the same tendency.

Two more medical men have come forward as parliamentary candidates. Mr. Ernest Hart, the editor of the *British Medical Journal*, has come forward for a constituency in East London. Mr. Erichsen, late President of the English College of Surgeons, has appeared as a candidate for the Universities of Edinburgh and St. Andrew's. Mr. Erichsen has already received considerable support, though he has not the advantage of being an alumnus of either university. He is, though, an honorary graduate of the former university.

Mr. Wharton Jones, F.R.S., late Professor of Ophthalmic Medicine and Surgery in University College, London, has been busying himself in his retirement at Ventnor by penning a series of articles which are calculated to make some of our physiologists rub their eyes and ask themselves whether they are asleep or awake. The emigration of leucocytes is now taught as a well-established incontrovertible phenomenon. Mr. Wharton Jones believes that there is no such thing, and says that he has not yet been fortunate enough to meet with any professor who could satisfy his doubts from experience of his own, or demonstrate the fact to him. The suggestion is made that the belief of "hundreds of trained workers" in the phenomenon may be a mere parrot utterance. Those, he says, of whom he has made inquiry acknowledged that they had not observed the phenomenon. Mr. Wharton Jones similarly criticises unsparingly many other articles of faith in vascular physiology and pathology, and challenges the production of proofs. The physiologists meanwhile seem in no hurry to take up the gage he has thrown down. Is it because they are conscious of their own weakness, and that, in fact, many of them have not sufficient practical experimental knowledge of the points at issue to contradict Mr. Wharton Jones?

"A MEDICAL VIEW OF ARMY MORALS."

To the Editor of The Medical Record.

Sir: In a communication published in The Medical Record July 11, 1885, exception is taken to a remark attributed to Professor Gross. That this venerable surgeon may have been mistaken in ascribing a specific taint to the scrofulous children of all soldiers is possible, but I do not think it has been shown that he was. Your correspondent supplied facts and figures to repudiate the insinuation, which he declares to be untrue. Let us see with what result. He cites "three hundred and eighty careful and prolonged examinations of soldiers made during the last year," etc.; in only one was positive evidence of "syphilis found, and in five only was there presumptive evidence." The medical statistics of the Provost-Marshal-General's Bureau give the ratio of soldiers examined and rejected for syphilis as 12.8 per thousand, which corresponds very closely with that above, provided the five presumptive cases be included.

Assuming the correctness of this ratio for the present as well as the past, let us take the assertions in the order stated in the communication and see if they are corroborated by the statistics given in those reports. Your correspondent asserts that "the young men today between twenty and thirty-five years of age" will show a much larger proportion with evidences of acquired syphilis. In the words of your correspondent "this is untrue." The reports show for those between twenty and thirty-five years of age a ratio of ten per thousand, the average for soldiers being twelve per thousand. He challenges "any profession in America, not excepting the clergy, college professors, and editors." Even the sanctuary is invaded. *O tempora! O mores!*

But here again the figures show the doctor to be in error. Referring to the same authority, which, be it remembered, was compiled by military officers, we fail to find *any* one profession in which the ratio is so large as in that of the soldier, the ratios being for those professions particularly alluded to in the communication as follows: Editors, 0; teachers, 3; clergymen, 7; and soldiers, 12 per thousand.

The doctor thinks "that American soldiers deserve better treatment at the hands of physicians." How is it with the clergy, college professors, editors, and young men? But I see no ground for assuming the treatment to have been bad. Prophylactic measures might result in some good, but the laws of our land have placed no such powers in the hands of the profession. If "a careful examination of soldiers now living" should give a less proportion affected (?), however gratifying such a result might be, it would not affect the remark made by Professor Gross, which had reference to the past and not the present.

Would it not be better to divest such questions of sentiment and deal with them in the light of modern physiological and sociological laws, recognizing the causes and results, hoping for some improvement in the future, and not forgetting the injunction of that intrepid old lecturer, who was wont to turn upon his hearers, whose faces depicted horror and disgust at these unfortunate patients, and remind them that they should not show their disgust, but rather pity, for if they were fortunate enough to have escaped themselves, it was due more to good luck than any credit on their part?

Yours, Medicus.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 2, 1885, to August 7, 1885.

BILL, JOS. H., Major and Surgeon, U.S.A. Died, at Yonkers, N. Y., July 21, 1885.

MCDOUGALL, CHARLES, Lieutenant-Colonel, U.S.A. (retired). Died, at Fairfield, Va., July 25, 1885.

DEWITT, CALVIN, Captain and Assistant Surgeon. Promoted to Major and Surgeon, vice Bill, deceased, to take effect from July 21, 1885.

IVES, FRANCIS J. Appointed Assistant Surgeon, with rank of First Lieutenant, to rank as such from July 25, 1885.

GIRARD, A. C., Captain and Assistant Surgeon. From the Department of the East to the Department of Columbia. S. O. 170, A. G. O., July 27, 1885.

EBERT, R. G., Captain and Assistant Surgeon. From the Department of Columbia to the Department of the East. S. O. 170, A. G. O., July 27, 1885.

TESSON, L. S., Captain and Assistant Surgeon. Ordered from Fort Stockton, Tex., to Fort Davis, Tex. S. O. 90, Department of Texas, July 27, 1885.

CARTER, W. F., Captain and Assistant Surgeon. Ordered for duty as Post Surgeon, Fort Stockton, Tex. S. O. 90, Department of Texas, July 27, 1885.

APPEL, A. H., Captain and Assistant Surgeon. Ordered for duty with the United States troops forming portion of guard of honor over remains of ex-President General Grant, at Mount McGregor, N. Y. S. O. 36, Division of the Atlantic, July 29, 1885.

GORGAS, WILLIAM C., Captain and Assistant Surgeon. Granted leave of absence for two months, to take effect about August 10, 1885. S. O. 169, A. G. O., July 25, 1885.

BROWN, J. M., Surgeon; EWEN, CLARENCE, and TAYLOR, A. W., Assistant Surgeons. Ordered to rejoin their proper stations in Department of the Platte. G. O. No. 7, Division of the Missouri, August 1, 1885.

EDIE, G. L., and BLACK, C. S., Assistant Surgeons. Ordered to rejoin their proper stations in the Department of Texas. G. O. No. 7, Division of the Missouri, August 1, 1885.

POWELL, J. L., Captain and Assistant Surgeon. Assigned to temporary duty at Fort Leavenworth, Kas. S. O. 110, Department of the Missouri, July 30, 1885.

DIETZ, WM. D., First Lieutenant and Assistant Surgeon. Ordered from Fort Selden to Fort Stanton, N. M. S. O. 111, Department of the Missouri, July 31, 1885.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ending August 1, 1885.

FESSENDEN, C. S. D., Surgeon. Leave extended ten days on account of sickness. July 27, 1885.

GODFREY, JOHN, Surgeon. Granted leave of absence for thirty days. July 29, 1885.

IRWIN, FAIRFAX, Passed Assistant Surgeon. To proceed to Richmond, Va., and Wilmington, N. C., as inspector. July 28, 1885.

AMES, R. P. M., Passed Assistant Surgeon. Granted leave of absence for thirty days. July 27, 1885.

THE RELATIVE ESTIMATION OF DOGS AND DOCTORS.—In Michigan they assess a dog $1 for being a dog. In Tennessee they assess a man 50 cents to become a doctor. It costs half a dollar more to be a dog in Michigan than a doctor in Tennessee. Don't be a dog.—*Battle Creek (Mich.) Moon.*

Aug. 8, 1885	0	3	3	4	18	18	0	0

A "FAITH CURE."—At a recent meeting of the Philadelphia Clinical Society, Dr. D. M. Barr related a case of so-called faith-cure which had come under his personal observation. He had first seen the patient, a lady, forty-nine years of age, in January, 1879. She had then been suffering at intervals for several months from severe uterine hemorrhages. Examination revealed a cauliflower excrescence involving the posterior and part of the anterior lip of the os uteri. This was removed by the écraseur, the wound healed kindly, and for two years and a half the patient enjoyed excellent health. At the end of this time she again had uterine hemorrhage, and examination showed the presence of specific granulations covering the entire endometrium. These were destroyed by Vienna paste, and the patient passed another year of apparent health. Hemorrhage recurring again, another examination was made, and the epitheliomatous growth was seen to involve the vagina and the body of the uterus. The patient was greatly alarmed, refused all nourishment, and seemed to be rapidly approaching dissolution. At this juncture she was persuaded to try the faith cure, and after being prayed over and anointed she declared herself cured. And so she was to external appearances; she felt well and strong and was able to endure almost any exertion, and she looked so much better that Dr. Barr did not recognize her when he saw her three months later. She remained in this condition about a year when she began again to fail. She was again examined and the cancer was found to have been increasing steadily; it now filled the pelvic cavity, and the enlarged uterus extended as high as the umbilicus. She died a short time after this. In the discussion which followed this report, Dr. Montgomery related the case of a lady suffering from an organic heart affection who was desirous of trying the faith cure; but the examining physician told her that such cases were not benefited by that method of treatment.

PROLONGED GESTATION.—Dr. A. H. Crawford, of Buffalo, N. Y., relates the following case as one of presumably prolonged gestation: "Mrs. G——, married six years and the mother of two children, had always, except during pregnancy and lactation, been perfectly regular in her menstruation, the periods extending over a week in each calendar month. She menstruated the last time on June 15, 1884, and from that date considered herself to be pregnant. She first felt motion in December, if she remembers correctly, but is certain of having noticed it early in January. The child was not born until June 27, 1885, one year and twelve days from the last menstrual period. The infant was a girl of medium size, with an abundance of hair, but with no other signs of increased development. The mother was a perfectly healthy woman and had no uterine trouble or other condition than pregnancy to account for the cessation of the menses."

A Contribution to Hepatic Surgery.— Dr. C. G. Roehr, of Milwaukee, has been experimenting upon dogs and cats with a view of determining how well they would bear the removal of portions of the liver or gall-bladder. After opening the abdominal cavity he ligated a portion of the liver by a continuous double catgut suture drawn so tight as to cut through the hepatic substance while only compressing, but not dividing, the vessels. He then excised the portion lying on the distal side of this suture and closed the external wound antiseptically. The animals survived the operation, and subsequent examination showed the wounded surface of the liver adherent to the omentum and peritoneum. The catgut ligatures had been absorbed. In two cats he operated in a similar manner, excising a portion of the gall-bladder, having previously drawn off the bile. The cats were afterward killed, and the wound in the gall-bladder was found cicatrized, no adhesions being found with the neighboring parts.

Acute Inflammation of the Thyroid Gland.— Dr. E. B. Ward, of Greensboro, Ala., writes: "I see reported in the last Record a case of acute inflammation of the thyroid gland in a Bohemian woman. I would be glad if you will give space in your valuable paper to a report of a similar case occurring in an American woman. The lady had no goitre at all, no enlargement of the neck of any kind previous to this acute swelling; she was over fifty years of age, mother of a large family. She told me when I was called to see her that I was the first doctor she had ever had attend her. Stature was short and full, resembling very much the Swiss or Bohemian. The enlargement when I saw it had attained to considerable size, fully as large as a good-sized cocoanut. She suffered considerable pain at night from it. It did not interfere with deglutition or respiration. Iodine was injected into the tumor, suppuration came on, and when the knife was used to open it the pus shot out like water from an artesian well; at least a teacupful of pus was discharged. The patient convalesced without any more trouble."

Cold Hands and Feet.—Many people suffer from this trouble all their lives. They have difficulty in keeping the feet or hands warm in winter, and slight exposure to cold or mental excitement at once asphyxiates the extremities. These people generally suffer also from a palmar and plantar hyperidrosis. They constitute the class out of which the different forms of Raynaud's disease are drawn. Local and general exercise daily, hot pediluvia containing tr. capsici, general tonics, warm absorbing covering to hands and feet, are the therapeutic measures indicated.

Rhus Toxicodendron and Rhus Aromatica.—A correspondent from Boston writes: "Permit me to call your attention to a paragraph in your issue of July 25th, which you entitle, 'Rhus Toxicodendron in the Treatment of Enuresis.' The text says, 'rhus *aromatica*.' The distinction is not unimportant, as rhus toxicodendron is, as its name implies, poisonous, being the 'poison ivy,' while rhus aromatica is not so. If Dr. Willeford knows anything in favor of rhus toxicodendron (which is officinal), I wish he would say so."

Some Notes on the Dosage and Therapeutic Value of Convallaria.—Dr. Z. P. Dellenbaugh, of Cleveland, O., writes: "In The Medical Record for June 27, 1885, p. 706, Germain Sée is quoted as giving convallamarine to children in one-third to two-third grain doses. About one year ago McKesson & Robins supplied convallamarine in $\frac{1}{100}$ gr. pills, and cautioned the profession to only gradually increase the dose of one pill. As the discrepancy is very great, would you be kind enough to note in your next issue whether the translator has not confounded the extract of the drug with the alkaloid." Doubtless the aqueous extract was meant instead of the glucoside convallamarine. The alkaloid convallarin is inert. The dose of the aqueous extract of the whole plant is from gr. v. to gr. viij. t. i. d. Dr. Dellenbaugh adds: "I have used convallaria quite freely since its introduction to modern practice, and find the infusion, if anything, more efficient as a diuretic in feeble heart cases than digitalis. Though not as pronounced as digitalis in increasing the length of cardiac systole (not diminishing the number of contractions so well as digitalis), convallaria, being so much safer, I have relied on it to maintain the energy obtained by the digitalis, and am quite well pleased with the results."

The International Medical Congress, which is to convene in Washington, D. C., in 1887, it is to be feared will be a flat failure, on account of the questions of medical politics and geography which have been raised by a few gentlemen who are anxious to play the rôle of Atlas to the medical world. Since the action of the committee at Chicago, scores of eminent physicians, whose names shed the brightest lustre on American medicine, living in Philadelphia, Boston, Baltimore, Louisville, and other large cities, have withdrawn and positively refuse to have anything to do with the matter. It now looks as though the Medical Congress will be like the play of Hamlet with Hamlet left out.—*Indiana Medical Journal.*

Demagogues of Medicine.—One more extract in regard to medical demagogues—a very true picture: On no profession does the demagogue, in the English, not the Greek, sense of the word, inflict more damage than on the medical. Yet in no profession, be the truth plainly spoken, will you find a larger proportion of demagogues. I do not refer to unmatriculated or unlicensed or unregistered malpractitioners. They are an odious class apart. I refer to those in regular though not in good standing. You will find them boasting of their cures. You will find them organizing Cheap John dispensaries. You will find them exaggerating ailments in order to magnify recoveries which Nature would have made more quickly had they been out of the way. You will find them declaring that old and disproved remedies are new and infallible cure-alls. You will find them proclaiming to wide-eared laymen their works of wonder. You will find them with a noisy constituency of half-educated men and wholly silly women championing them as if they were a national issue or an evangel of deliverance. . . . This sort of lying is a form of demagogy. It passes for miracle and gospel among the credulous. It limits a man for his audience to the low associations to which you will be tempted and against which I warn you. It is a compound of Munchausen and Mumbo Jumbo. It works on its claque or victims the awe the German explorer worked on the African savages—who worshiped him, gave him provisions, and free and safe passage, because he could wag his ears and had a startling trick of removing his false teeth.—Mr. St. Clair McKelway, in *Gaillard's Medical Journal.*

A Very Young Case of Gonorrhœa.—Dr. E. B. Ward, of Greensboro, Ala., writes: "I would like to ask if any of your many readers can report as young a case of gonorrhœa as this: Patient a negro boy, seven years old, with a specific discharge from the urethra. The patient had contracted the disease from an older girl, who used him for her vile enjoyment. I had another youthful patient, aged nine, last year, but this one 'takes the cake.'"

An Antiseptic Ointment.—Dr. E. B. Ward, of Greensboro, Ala., writes: "The antiseptic ointment mentioned in your last paper by Dr. M. B. Ward is very much like the one I have been using for some time in my practice. The one I use, and which has given splendid results in wounds and sores, is composed of iodoform, subnitrate bismuth, and vaseline. For chronic ulcers I add calomel to this. I have had wounds heal very readily with this ointment."

PULMONARY PHTHISIS.

By J. MILNER FOTHERGILL, M.D. EDIN., HON. M. D. RUSH. MED. COLL., ILL.

PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST (VICTORIA PARK).

PULMONARY phthisis is a very common malady, killing a perfect array of victims annually. Yet my experience, covering a period of nearly ten years, at a chest hospital, tells me that it is a malady which is far from being necessarily fatal. Indeed, in the large bulk of cases a rally is made which may lead to recovery. Where the patient is living under fairly favorable circumstances, such, indeed, is quite commonly the case. Unfortunately for hospital patients, they cannot live under favorable circumstances.

It may be well to start with the less grave cases—or where the disease is in an early stage—first. A patient presents himself, or herself, complaining of cough, and looking ill. Perhaps not very ill, but there is something which tells the trained eye that mischief is on foot. There is a certain pallor, with a dirty hue of the skin. Sometimes the skin is distinctly greasy, and then the outlook is darker. On inquiry, the story is pretty much as follows: cough, night-sweats, losing flesh, and a defective appetite. Physical examination tells of a consolidated lung-apex as far as the third rib. Such is the most common out-patient with commencing phthisis. As to the prospect of each patient, much will depend upon the family history. If that be good, there is usually little ground for apprehension. If it be bad, then the case demands watchful care, and even then the result is doubtful.

As to how that lung-consolidation has been brought about, is a matter upon which it is difficult to say anything positive. It is there, and we know it to be due to a development of lowly connective-tissue corpuscles along the tiny blood-vessels. The fewer the corpuscles and the better their quality, the more favorable the prospect; the more profuse the production of them, the lower their quality, the more they crowd on each other, and the more likely is subsequent softening. How are we to distinguish these cases? Largely by the family history and the history of the patient. If it were practicable to take the temperature night and morning—which is not the case with hospital out-patients—light would be thrown on the difficulty. If the temperature keeps pretty even, the outlook is good. If the evening rise is marked, then a less hopeful outlook exists.

How is such a case to be treated? In one hospital of repute the routine treatment is quinine and cod-liver oil; not a bad line to take, but scarcely elastic enough for a malady which has such a variety of aspects. What is it we wish to achieve in such a case? That is the first question. We wish to procure absorption of the neoplasm, if possible. Failing that, we wish to save it from molecular necrosis—softening tubercle. Under favorable circumstances the lung may clear up. Our object is to raise the quality of the new growth, and that cannot be done directly, but only by improving the general nutrition. If we cannot achieve absorption, can we keep the new cell-growth from death? Even if some portion do soften and break down, can we save the rest, or build up healthy tissue around the perishing areas?

Our line of attack, then, is to improve the general condition, in which improvement the new growth will have its share. To check the body-expenditure and to increase the body-income are our aims. All outgoings must be stopped. That is the first step—to my mind. If a woman, attend to any leucorrhœa at once. Many a good line of attack has failed, many a woman sunk into her grave who might have been rescued, if only that outgoing had been attended to. If the catamenial loss be heavy, put an arresting finger upon it by some ergot, sulphuric acid, and sulphate of magnesia, commencing with this two days before the appearance of the flux, and continuing it during the flow, reverting to the usual treatment on its completion. "A penny saved is a penny gained;" and this is true of phthisis, almost more than anything else. Then, is there diarrhœa? If so, attend to it. Milk and farinaceous matters are indicated (no meat-broths, no beef-tea—"giving the patient a stone when he asks for bread"—unless some farina be added). Then for medicine some astringent preparation of iron may be given in the day, and a pill of sulphate of copper (gr. $\frac{1}{4}-\frac{1}{2}$) with opium (gr. $1-1\frac{1}{2}$) at bed-time. If there be both diarrhœa and night-sweats this pill will often "kill two birds with one stone."

If there be night-sweats, arrest them at once, or as soon as may be. Sweat is an excretion, and is highly charged with blood-salts. Consequently, profuse sweats are most exhausting. Check them, and the appetite returns, and between the two the patient does well. To my mind, Professor Sidney Ringer, F. R. S., has laid the phthisical world under a deep debt of gratitude by pointing out the potency of belladonna in the matter of hydrosis. The best preparation is atropia, not only because it is tasteless, but because we know exactly what we are doing when using it. But to secure its good effects it must be pushed. Its effect upon the pupil is nothing. Indeed, in a very extensive experience of belladonna the pupil has rarely been affected. (The effect upon the pupil is a bugbear which ought to be buried). Dry throat and dim eyesight are discomforts, but unless severe they need not disturb the treatment. There is a wide gulf between these and any real danger. The very lowest dose is $\frac{1}{75}$ of a grain. If this does not achieve the desired end, then $\frac{1}{50}$. If that is insufficient, then $\frac{1}{25}$. If that fails—which it rarely does—I begin to look seriously at the case. (And here I must do an ungracious act. No one knows better the high claims Dr. Lauder Brunton, F.R.S., has upon therapeutists than the writer. Personal knowledge is added to knowledge of his writings. But, admitting all this, I cannot but regard his commencing dose of atropia ($\frac{1}{100}$ of a grain) as far too small. It is given in his new work on "Materia Medica and Therapeutics," a work of which the profession may justly be proud, and which must be a guide to all. But in this matter it trips). One patient passed a comfortable night with two pills of $\frac{1}{25}$ of a grain in her stomach. When this dose is reached, and yet the sweats continue, I adopt the plan of an old New York quack, of which Lewis Sayre told me, viz., to sponge the patient over with hot vinegar ($\frac{1}{2}$ pint) with a teaspoonful of cayenne in it. This is not at all disagreeable, and is effective. If the combined measures fail, the patient's case is hopeless, but his physician's conscience is clear.

Perhaps the patient's rest is broken by cough. All familiar with consumption know that if the patient fall into a deep sleep hydrosis comes on. If he keep awake he

either does not sweat or the sweat is moderate in amount. The first effect of an accumulation of carbonic acid in the blood is to rouse the respiratory centre to greater respiratory efforts. If that is not sufficient, then the sweat-glands are brought into operation. Unfortunately, the sweat has other constituents than CO_2. It is well to keep this bit of physiology in mind. Belladonna is a potent stimulant to the respiratory centre; it also exercises a profound influence upon the sudoriparous glands. Consequently, it is of the highest value in the matter of night-sweats. By the combination of atropia and opium night-sweats can usually be kept in check. Morphia (gr. $\frac{1}{8}$), atropine (gr. $\frac{1}{100}$), with pil. galban. co. or "pil. al. et myrrh.," as the case may require, is a pill which has done me yeoman service in my warfare with phthisis. It has found its way into the Brompton Hospital, and more recently into Squire's "Companion to the Pharmacopœia." It will find its way before long into every consumption hospital in the world. This action of carbonic acid upon the sweat-glands has led Dr. Lauder Brunton to advocate strychnine (a potent stimulant to the respiratory centre) in the night-sweats of phthisis. No doubt it is useful. My practice is to give it in the day-medicine. My favorite mixture at the hospital consists of liquor strychnine (♏iv.), acid. phosph. dil. (♏xv.), tinct. capsici (♏ iv.), in infus. gent. (℥ j.), *ter in die*. This forms a capital tonic. Some quinine or sulphate of magnesia (or soda) may be added as required.

One of the rules which have formed themselves in my mind is to give acids when the tongue is clean or coated. When the tongue is bare, raw, or irritable, then alkalies are indicated, as am. carb. (gr. ij.–iv.), tinct. nuc. vom. (♏x.), inf. gent. (℥ j.), *ter in die*.

On such a line of treatment the patient usually improves. The night-sweats cease, the appetite returns, the cachectic look departs, and the patient feels much better. The improvement is maintained, and soon iron and arsenic can be added to the strychnine, and cod-liver oil to the dietary (but cod-liver oil is not the best form of fat, nor yet the most palatable, though it is the most digestible. Some forms of fat in an emulsionized state are now on the market which possess many advantages over cod-liver oil). Iron is a good hæmatinic.

Arsenic is an alterative and a tonic greatly believed in by many good observers in lung-consolidation. If the patient can be induced to take fat in any form, the healthy tissues can be built up. Very commonly the affected area is found to shrink, and air to pass into it. In a few months, in many cases, it is scarcely possible to detect any change in the lung. The threatened danger has passed away!

How far external applications of iodine are of service, I cannot say, knowing little about them. Some good men think highly of them.

All along in the treatment advocated the matter of improving the general condition has never been lost sight of for a moment. If the patient can get away to a dry soil and a bracing locality, all the better for him or her.

Another common patient is the person who has chronic phthisis with cavities. Such patient is always spare and badly nourished at the best; and when any intercurrent ailment still further lowers the general condition the lung trouble is aggravated. (And one matter has forced itself upon my attention, viz., that wherever there is old lung-consolidation any disturbance in the liver sets up irritation in this consolidated patch with resultant cough. And this cough, which is intractable to ordinary cough-medicines, is relieved by acting upon the liver.) The appetite has fallen off and the nutrition is impaired; and then the special danger in phthisis is set up. Very often the tongue is raw, or beefsteaky, or patchy. Here attention to the *primæ viæ* (as our grandfathers phrased it), is imperative. The patient must be sent to bed, to reduce the body expenditure to the minimum. The medicine must be bismuth, with alkalies; and the food, milk with malt-extract, or a malt preparation like Mellin's food, in small quantities at a time, oft-repeated. Any bulk of food is rejected by the irritable stomach (which remembers the offence), and so the dietary must be arranged accordingly. Even a blister over the stomach, with some powdered opium or morphia dusted over the raw surface, may be indicated. In young patients there is another reason for such food, and that is the danger of starting up tubercular ulceration in the bowels. It frequently happens that a poor patient when taken into the hospital is put upon the usual dietary, with the result of disturbance being at once set up in the alimentary canal. The bowels have not been accustomed to such food, however simple it may seem to well-fed persons. Again and again has this occurred in my experience; indeed, with almost every new clinical assistant, who has to learn—as I did myself by painful experience—what a very poor pasture these hospital patients come from. Some fish and potato—which the patient enjoys, doubtless—are enough to start up a diarrhœa which is troublesome, and sometimes, despite all we can do, passes on to tubercular ulceration and death. The food should consist of milk and malt, or meat-broth with biscuit-powder in it. No solid particle in it to vex and irritate the sensitive (because ill-fed) mucous membrane. Even an alkali—like carbonate of magnesia—may be required to neutralize acidity and prevent too firm curdling of the milk; as much as will lie on a sixpence to the half-pint of milk is usually sufficient. Having got the assimilating processes into good working order, the tonics may be given. "The more haste the less speed" is specially true of the treatment of phthisis; and the desire to push on with tonics and good food sadly too often defeats its own end. Sometimes a masterly inactivity is the wisest practice. A clear head and a firm will are often required to curb the desire of the patient (and still more the patient's friends) to be getting on. Back-cast after back-cast teach a painful lesson to the medical man, and involve the patient in acute danger. If the pressure put on a young medical attendant is becoming more than he can bear, let him call in an older head to help him.

And now as to what must *not* be done. The chief thing to avoid is morphia linctures for the cough. An opiate to procure sleep may be essential and unavoidable; but sedatives in the day are dangerous. They give relief from the cough—granted; and too commonly they give permanent relief by death. Opium lays its palsying hand upon the assimilative organs, and destroys the appetite. Its evil effects seem most distinctly felt by the liver. When an opiate is indicated at night it should be combined with ipecac to antagonize its effect upon the liver, and with aloes and myrrh pill to correct its action upon the bowels. The morphia linctures is unknown in my wards except under the most peculiar circumstances, or until all hope has been abandoned and the treatment is a matter of euthanasia. Opium strikes directly at that assimilation which is to my mind the cardinal matter in the treatment of phthisis. I would rather have to deal with a large area of disease in the lungs where the assimilation is good, than a smaller patch if the appetite is bad and the nutrition defective. The patient most certain to die, the case least amenable to any treatment, is that one whose wasting progresses steadily, and where the lungs are only affected quite late on—indeed, a brief while before the final change sets in.

As to other means of allaying the cough than opiates, inhalations of steam are often serviceable. Friar's balsam, iodine, carbolic acid, terebene, eucalyptus, all are good as additions to the steam. Where there is a cavity with ragged walls smelling offensively, a respirator with cotton wool charged with carbolic acid is indicated. (Of treatment specially directed to the extinction of bacilli I know nothing personally).

Then, as to other means of feeding the patient, there are inunctions of oil, often of service, especially with young subjects. Nutritious enemata have only lately suggested themselves; but in one case of a medical man steadily

wasting, an enema of cod-liver oil (emulsionized by a drop of bile) and milk in equal quantities is being tried. In appropriate cases in the hospital the plan is about to be tried. Such enema night and morning, while in the recumbent posture, would be readily retained. When the temperature mounts up, and especially when the skin is also moist (the usual state in hectic fever connected with phthisis), my plan is to give quinine (gr. ij.–v.), with tincture of digitalis (♏. x.–xv.) and dilute phosphoric acid (♏. xv.), thrice daily. The effect is very satisfactory usually. Where a severe racking cough is present, shaking the poor sufferer terribly, it may be necessary to give opiates; but, in my experience, such cough is very rarely found with pulmonary phthisis.

Hæmoptysis has so far escaped notice. The treatment of hæmoptysis is quiet; no movement, no talking. When it arises from the bursting of an aneurismal sac in a cavity, or from an ulcerating process eating into a blood-vessel and opening a communication between the vessel and an open air-tube, syncope alone is likely to arrest it. In congestion of the lung it is often an excellent form of local bleeding. Men of old bled for its relief; now free purgation with mineral salts is in vogue. For small recurrent hæmoptyses the best treatment is to keep the bowels open. Ice, ergot, and dilute sulphuric acid may also be tried; probably they will do no harm. It is a bad plan to feed up a case of recurrent hemorrhage; it only fills the vessels rapidly, to end in more bleeding.

Finally, the management of phthisis pulmonalis, whether the less grave or the more serious conditions, is a good test of the knowledge, skill, and tact of the practitioner, who must, like a competent soldier, be able alike to plan a campaign or execute a sudden change of front in an emergency. That is, he must be able to lay down a persisting plan of treatment, and promptly change his plan to meet some intercurrent condition, as hæmoptysis or acute gastric disturbance.

HEADACHE AND OTHER REFLEX-NERVOUS TROUBLES AS THE RESULT OF EYE-STRAIN—WITH SIX ILLUSTRATIVE CASES.

By A. R. BAKER, M.D.,

PROFESSOR OF DISEASES OF THE EYE AND EAR IN THE CLEVELAND POLYCLINIC AND POST-GRADUATE MEDICAL SCHOOL.

Case I.—Miss B——, aged twenty, was not able to read at night for several years. Left school on account of "weak" eyes. Never had any pain in the eyes, but had been an almost constant sufferer from frontal headache. Could not sew on striped goods, and walking behind a person with a striped dress always made her dizzy; and several times, when ironing striped material, she became so sick as to produce vomiting. She compared her feeling at such times to being sea-sick. She had compound hypermetropic astigmatism, and when corrected was entirely free from all her unpleasant sensations, and could read all night, as she expressed herself a year afterward.

Case II.—Mr. E——, aged twenty-nine, principal, public schools, has been a sufferer from periodical headaches for ten or fifteen years, returning regularly two or three times a month. During vacations he was free from headaches, unless he attempted to read, which he avoided as much as possible. Attacks were so severe as to incapacitate him from work for two or three days, and he would have been compelled to resign his position if it were not that his headaches usually commenced on Fridays and he was able to return to work on Mondays. The only way in which he could get relief from the intolerable pain was from the hypodermic use of morphia. The quantity had gradually been increased, until several grains were required, and as the result his bowels and digestive apparatus were always in a bad condition. Since being corrected for a high degree of compound hypermetropic astigmatism he has not had a single attack of headache, a period of almost two years.

Case III.—Fred. A——, aged nine, never had any trouble with his eyes, until, after an attack of measles, he was suddenly taken with what he was pleased to call "blinking," and was not able to read and compelled to leave school. Upon every effort to read there was a spasmodic opening and closing of the lids almost choreic in character. Eyes water, and feel weak and somewhat sensitive to light, but no pain in head or eyes. There was about 1 D. of hypermetropia, and when corrected he was able to return to school and do his work with no further trouble. Several attempts have been made to get along without the use of the spectacles, each time with a return of the "blinking."

Case IV.—Frank W——, aged twelve, ever since he had measles, six or eight years ago, has had trouble with lid margins. They are red, lashes gone in places, at others matted together in pencils. Margins of lids scaly, with small scabs scattered irregularly, covering small ulcers; lids slightly everted, showing a little of the conjunctiva, giving the eyes a red unpleasant appearance. The boy has been under almost constant treatment for years, sometimes better, sometimes worse, but never any permanent improvement. I suspected hypermetropia at once, but from a hasty examination without atropia I failed to discover any. After treating the case unsuccessfully for some time, I paralyzed the accommodation thoroughly with atropia and unmasked 1 D. of latent hypermetropia. I gave him a pair of spectacles, with instructions to wear them constantly. At the end of one month, with no other treatment, the lids were looking quite well, and in two months they were perfectly well.

Case V.—Master Willie P——, aged six, brought to me two years ago with convergent strabismus. I corrected his hypermetropia fully, with suitable spectacles; in a few days his eyes became straight and have continued so up to the present time.

Case VI.—Miss Alice K——, aged fourteen; since a child the hair on top of her head has never grown over half an inch in length. It is coarse, hard, and curly, ends broken and split; looks very much like the hair of a negro. On the back part of the head the hair is fine and glossy, and would grow several feet in length. Family history good; general condition good. The skin is apparently healthy, and no cause could be assigned for the condition of her hair. She had consulted leading dermatologists, both at home and abroad, and undergone treatment, externally and internally, from physicians regular, irregular, and defective. She has suffered at times severely from headaches, but in other respects has always been healthy. I was consulted on account of her eyes giving her some trouble in school during the winter. Eyes tired easily and suffered more than usual from headache. I found she was hypermetropic and prescribed glasses accordingly. As I expected, she was freed from headache, but I was somewhat surprised to learn that her hair commenced growing at once; at present it is fine and glossy, reaching to her waist, and no difference is to be noted between that on the top of her head and elsewhere.

Whatever theory we may maintain with regard to the relation of the sympathetic to the cerebro-spinal nervous system, and the influence one exerts upon the other, the well-known experiments of Claude Bernard, of dividing a branch of the sympathetic, is known to exert a very decided influence upon the circulation, calorification, secretion, and nutrition of the parts to which it is distributed; while exciting the same nerve by the galvanic current or otherwise, produces a series of phenomena exactly the opposite. From these well-known considerations, as well as from the clinical observation of reflex nervous troubles in various organs distant from the source of irritation, such as the vomiting of pregnancy, pain in the knee from morbus coxarius, pain in the penis from the irritation of stone, supraorbital neuralgia as the result of dental irritation, cough as the result of a plug of wax in the ear, etc., it can be easily understood how the constant irritation produced by the incessant eye-strain,

as the result of hypermetropia or astigmatism, might cause the intense headaches, the dizziness and sickness of the stomach, the reflex nervous disturbances of almost every organ, and even the disturbance of nutrition which prevented the growth of hair, as in Case VI.

The sickness at the stomach and dizziness I have found quite a frequent complaint in astigmatism, usually accompanied with more or less headache. One case I remember fitting with spectacles some years since said that even the mention of a barber's pole made him feel uncomfortable about the pit of his stomach. The patient's comparison of her sensation with that of sea-sickness is very *apropos*, as the cause in both cases is similar. One of the principal causes of sea-sickness is the constant effort required to accommodate the eye to constantly changing distances; the same is true of riding on the railroad, swinging, etc.

In cases of refractive error the pain very frequently is not referred to the eye itself. In fact I think it is rather exceptional where such is the case. Pain is usually complained of either in the frontal region, temples, or back of the neck. Dr. S. Weir Mitchell, in an article in the *American Medical Journal*, 1874, says, "that while there may be no pain or sense of fatigue in the eye the strain is interpreted solely by the occipital or frontal headache." The patient, when interrogated, will usually say that the eyes are "weak," and "blur," and get "tired" easily, but seldom associate their headache with their eyes. It is not to be imagined that every headache is the result of error of refraction, no more than that every case of infantile convulsions is due to an elongated prepuce. But when no other cause can be discovered, *every case of headache should be examined carefully for errors of refraction.* The accommodation should be thoroughly paralyzed with atropia, as the hypermetropia may be latent, as in Case IV., and not be discovered by the use of test-types. It is not unusual to meet hypermetropes wearing concave lenses fitted by opticians.

Cases of blepharitis marginalis are met with daily as the result of refractive troubles in ophthalmic practice. I usually recognize cases of hypermetropia in children as soon as they enter the consultation-room, from the condition of the margins of the lids, especially in dispensary practice, where strict attention to washing off the scales is not observed. If this constant eye-strain produces such marked changes on the lids, what must be the result on the eye itself?

Convergent strabismus is the result of hypermetropia, and could be prevented if glasses were fitted and worn early enough. Children four years of age will wear spectacles without trouble. The benefit to be gained from wearing spectacles early is not only the avoidance of an operation, which is a secondary matter, but it preserves binocular vision, which is of very great importance.

Damiana and the Mormon Elders.—Dr. W. B. Parkinson, of Utah, writes to the *Medical Age:* "I notice that in your issue of April 10th, you copy an article from the *Keystone Medical Journal*, by F. A. Evans, M.D., on the use of damiana, in which he accredits the Mormon elders with using the drug extensively to keep up 'their wasted energies.' I simply wish to state, in behalf of a much-abused people, that I have practised medicine among them for three or four years, extensively, and have never had one single case of impotence. Have only had one case of syphilis and one of gonorrhœa, and they occurred in 'black sheep.' Have known the benefits and uses of damiana, and I, with many other physicians, can testify that the Mormon elders do not use the drug as our worthy brother gives them credit for doing. The object they have in marrying more than one woman is to rear a stronger progeny. When a woman becomes pregnant, they *let her alone* and cohabit with another. I say *fair play*—'Give the devil his due.' The Mormons are often misrepresented."

SCIENTIFIC VALUE OF THE MORTALITY CENSUS.

By WILLIAM GILMAN THOMPSON, M.D.,

NEW YORK.

Probably no branch of the census indicates an expenditure of greater labor with less actual benefit to anyone than the "Mortality and Vital Statistics of the Census of 1880,"[1] just published after five years' work. Not that Dr. Billings has not done all that was possible to tabulate the returns in scientific and practical form, but the liability for error is so great, amounting in the aggregate to thirty per cent., and in special cases to much more, that any reasoning based upon the tables must be conducted with great caution. The errors are due to the vast size and wide distribution of our population, to the constant immigration and migration, and more than all to the absence of systematic local records of vital statistics. Had we a paternal government, like, for example, that of Germany, where a policeman or some official with a note-book follows your every move, our statistics might be worthy of more credence; but with our happy independence, and the total absence in many parts of the country of requirements for registration of vital statistics, and absence of any guarantee of the respectability of those calling themselves physicians, scientific accuracy is wholly impossible. A vigorous attempt was made to secure a nearer approach to accuracy in the present census than has been obtained heretofore. Blanks were sent in advance to physicians in all parts of the country, excepting in a few large cities where careful mortality records are kept. These blanks were to be filled with vital statistics for the year and returned. Only thirty-seven per cent. of the physicians addressed returned their blanks, on which 166,896 deaths were reported. (The total number of deaths for 1880 was 756,893.) The census enumerators, meanwhile, covered the same ground, and failed to report 61,020 of the deaths reported by physicians (!), although they of course reported a great number of additional deaths. (A similar discrepancy existed between enumerators' returns and the regular city records, where they overlapped.) This seems an incredible error, but it is made even more confusing by some of the diagnoses returned upon the "physicians'" blanks. Dr. Billings cites a few of these: "Struck in on the Aire Sells." "Yaller Ganders of the Liver," "New Money Fever," "Colory in Phantum," "Tecis" (!). Autopsies were obtained in 21 cases in every 1,000, and 49 cases in every 1,000 of all ages could not be diagnosed. A number of improvements have been made in the census of 1880 over that of 1870. Thus, in more or less chronic cases the place where the disease was contracted was ascertained, and the place of birth of parents of decedents, and names of their attending physicians were recorded. In former censuses the unit of locality employed was the State or Territory. This, being an arbitrary political division, was of little value. It was also too large, for the interest of a census depends upon how near home it is brought to individuals. So in 1880, in addition to the previous form of tables, which was retained for comparison, such counties as have a population of 10,000 and over were separated and arranged geographically in twenty-one grand groups, an attempt being thus made to compare the death-rate with the topography of the country. Such groups, *e.g.*, are "heavily timbered region of the Northwest," "prairie region," etc. In addition, the vital statistics of fifty large cities have been separately tabulated. In most of these cities the records have been obtained directly from the local health boards, etc., and this constitutes by far the most accurate part of the census. The race statistics have been extended to include, in addition to the whites and negroes, Indians, Chinese, and children of Irish and of German parentage. There is much in a mortality census which might be of value in a coun-

[1] Report on the Mortality and Vital Statistics of the United States, Tenth Census, Part I., June 1, 1880, by John S. Billings, LL.D., Surgeon, U. S. A. May 1, 1885.

try of a fixed population which is of very little use to us. What shall it profit physicians or anyone, to learn that in 1880 only one child died of measles in Wyoming, while eight children died of measles in New Jersey? Yet it has cost a great deal of time and of money to ascertain such facts. Dr. Billings himself admits the futility of the census in many respects, and calls attention to the fact that many of its tables which are of no value at present may serve as guides for future statisticians.

This is the fourth of the great mortality censuses of the United States. The first was taken in 1850. It is useless for the comparison of total mortality with previous censuses, and can be compared with them only for the proportion of deaths from different diseases and at different ages—and even in these respects it is valueless in many details; and it affords a pointed moral for our need of more harmony and common-sense in the nomenclature of disease. Thus among the causes of death in 1870, deaths from "alcohol" are classed under "Poisons," while in 1880 they are classed under "Alcoholism" in Group B of "General Diseases."

Addison's disease appears in 1870 as a disease of the "Integumentary System;" in 1880 as a disease of the "Absorbent System." In 1870 sunstroke is classed under "Nervous Diseases;" in 1880 it is cautiously placed among "Accidents and Injuries."

In 1870, "Old Age," "Still-born," and "Debility" are causes classed separately as "Conditions not necessarily Associated with General or Local Diseases," while in 1880 they appear under "General Diseases, Group C." In 1870, typho-malarial fever, hydrothorax, pyæmia, yellow fever, and typhus fever are all separately mentioned, but in 1880 they do not receive any notice, their place being absorbed by the non-committal division, "Fever."

Septicæmia and angina pectoris appear for the first time in 1880.

In 1870, "Worms" constituted a separate class. In 1880 they are placed under "General Diseases." The "Diabetes" of 1870 appears as "Glycosuria" in 1880, and, in brief, the old classification of 1870, which numbered one hundred and forty-nine divisions, has been reduced to one hundred and eight in the new census.

A handsome tribute to our advancing civilization is found in the facts that the deaths due to railroad accidents in 1870 numbered 1,461, and in 1880, 2,349; and the deaths referred to "Diseases of the Nervous System" in 1870 numbered 33,550, which increased in 1880 to 81,905 (!). "Consumption" seems to have progressed with utter disregard for the rate of increase in population. The deaths from this cause in 1870 were 33,971; in 1880, 91,270 (!).

The usual infantile mortality continues to be more than twice as great in the cities as in the rural districts, and more than two and a half times as many infant deaths occur from diarrhœal diseases as from any other single cause; next rank (2) convulsions, (3) diphtheria and croup together, (4) pneumonia. Whooping-cough is also very fatal; 36.3 deaths among every 1,000 deaths among infants under one year are due to it. The colored mortality continues much greater (2.54 per 1,000) than the whites, and it is enormous among infants under one month. The mortality of infants born of German parents is proportionally decidedly greater than among those born of Irish parents, but as a whole the Germans and Irish appear to lose their peculiarities regarding mortality after continued residence among us.

The proportion of deaths of females to males is as 931 to 1,000.

Far more Indians die of consumption than of any other disease, and as compared with white people, relatively more Indians die of measles, diarrhœa, malarial fever, and venereal diseases. The total death-rate for the country for 1880 was 15.09 per 1,000 of the population, according to the census, or 2.32 per 1,000 greater than in any previous census year; but Dr. Billings gives excellent reasons for not accepting these figures, owing to numerous unavoidable errors, and he estimates it at 18 per 1,000. This rate is slightly lower than that of any other civilized country, and thirty-three per cent. lower than that of many countries.

The last mortality census is quite an advance upon its predecessors, and praise is due to Dr. Billings for the indefatigable labor and skill he has bestowed upon it.

Reports of Hospitals.

HÔPITAL DE LA PITIÉ, PARIS.

CLINIC OF PROFESSOR VERNEUIL.

SPONTANEOUS FRACTURES—ECTOPY OF THE TESTICLE COMPLICATED WITH INGUINAL HERNIA; OPERATION.

(Reported by W. W. SKINNER, Externe des Hôpitaux.)

GENTLEMEN: We have in our wards a patient at whose bedside we stopped during a few moments this morning. This patient, a woman, aged sixty-five, is far from being vigorous for her age, and presents a very slight appearance of cachexia, but so feebly pronounced that it is impossible to determine its nature. Her personal antecedents are excellent. She has never been seriously ill in her life. Several years ago, however, she fell upon the palm of her right hand, causing a fracture of the forearm at its lower third. The fracture healed in a favorable manner and has remained consolidated. The patient is the mother of four children.

To-day we find her in the hospital on account of an accident which happened to her two days ago. It occurred in the following manner: She was about to climb into an omnibus, and seizing hold of the iron railing to aid herself, she took her place without having made any violent effort and without experiencing at that time any pain or any sensation of fracture or crepitation. But from that moment the left arm became powerless, for she could not raise it from its pendant position. The examination of the arm which you have seen me make immediately revealed abnormal mobility, having for its centre the middle third of the humerus. This sign of fracture was sufficient for the diagnosis, and others were not sought. It is evidently a case of fracture of the humerus by muscular effort.

It is worthy of remark that while the present fracture was unaccompanied by pain at the moment of its occurrence, so much so that the patient ignored the exact moment of its production, the first fracture, that happened several years ago, was accompanied with the usual severe functional signs.

Searching still for further the cause of this unusual fragility of her humerus, we do not find any symptoms of diabetes, neither by examination of the skin, nor by that of her urine, nor yet by interrogating her as to functional disorders; for the skin presents no eruption, the urine no precipitate by Fehling's solution, and there exists no polydipsia nor polyuria. Nor is there any sign of cancer, for the careful exploration both of the broken bone and of the viscera exclude that cause of fracture. There is, however, a hiatus in the analysis of the urine, for it has not been tested for excess of phosphates, and I am inclined, until a complete analysis shall prove me to be in error, to regard this fracture as caused by an abnormal fragility of the bones coinciding with *phosphaturia*. Should this prove to be the case it will increase the already accumulating records showing a relation between the production of spontaneous fractures and this alteration of the urine.

You have heard me speak of two patients reproducing this variety of fracture, one at the hospital, the other in my private practice. I will relate to you a *résumé* of this latter's history. The patient was also a woman, aged fifty-eight, robust, *gaillarde*, apparently in excellent health, with nothing of cachexia about her. Her arm was broken about a year ago and was properly treated so

that a good consolidation was believed to have been obtained. Six weeks ago an insignificant fall occasioned a sudden loss of power and voluntary mobility in the member formerly broken. Her physician examined the arm and sent the patient to me.

I found the humerus fractured; but when the lady came under my observation I suspected that she had diabetes, for this disease predisposes to fractures and to imperfect consolidation of fractures. Upon my suggestion she caused her urine to be carefully analyzed, and the principal results obtained are as follows: Absence of glucose; density, 1.027, which is high; urea, 41 grammes per litre (a figure not very astonishing considering the large amount of nitrogenous aliments the lady was in the habit of ingesting, as she was well-nourished); 4 grammes of *phosphoric acid*, which is nearly double the normal proportion; and very much uric acid and urates.

Thus it sometimes happens that fractures are caused by a very slight traumatism. You know that for their production there are two general predisposing *causes:* first, a *local disease* of the bone; second, a *dyscrasia* or modification of the general nutrition. There is no need to tell you that tuberculous or cancerous bones are broken with the greatest facility. You know that at the Salpêtrière, at Bicêtre, in asylums for the aged generally, but especially in cases of old women, fractures are often produced by the most insignificant causes; even the changing of the patients from one bed to another produces them.

Syphilis predisposes to these fractures. But when a syphilitic breaks a bone we know that there exists quite severe pain at the seat of fracture. There are, moreover, cases of fractures without tubercle, without cancer, without syphilis or cachexia whatever, in which no pain is felt either at the instant of the production of the solution of continuity, or subsequently. There exists, therefore, some other disease which coincides with this anomaly; that disease was formerly unknown, but is studied to day under the name of *phosphaturia*.

With your permission I will cite another instance of this dyscrasia. A fine lad of fourteen, apparently strong and healthy, was employed in serving masons. His work consisted in taking four bricks in his hands and throwing them to the man next to him, as is the custom here among bricklayers. On one occasion, while in the act of tossing them, the humerus on one side suddenly broke, to the great amazement of himself and of those who observed him. We sought, in explanation of this phenomenon, a dyscrasia, and found that his urine contained a great quantity of phosphorus.

You observe that we find a striking coincidence between fractures too easily produced and an exaggerated elimination of phosphates. This disease, phosphaturia, in its relation to fractures, is not yet thoroughly investigated, and we have only a few phases of its history in our scientific archives.

I am about to perform an operation of great interest, one which has not been frequently practised, and about which little has been published. It would be very desirable for some one to launch a monograph, or at least an essay, having for title something like this: "On the Coincidence of Affections of the Scrotum with Hernia from the Operating Point of View." Such a work would greatly help to determine whether an operation ought to be practised upon the testicle when the scrotum is occupied by a hernia. For my part, I have already operated twice in these conditions. The first patient narrowly escaped death from the operation; the second died. We will speak again of these cases a little further on. To-day I operate on a third, which will, I hope, prove a success.

That which is most interesting in the present case is the situation of the testicle to be removed. The patient is an adult, robust, vigorous, in the most favorable condition of health, but whose right testicle occupies the external ring of the inguinal canal, in which position it has remained since birth. Three months ago the patient made a violent effort which probably caused or confirmed the existence of the hernia, and since that moment the testicle has become swollen and painful. The progress of these symptoms has been so rapid that to-day we have decided to perform the operation of castration on the diseased organ.

Many similar facts have brought an *eclatante* confirmation, accepted by all, of the gravity of operation in cases of testicular ectopia. On the other hand, testicles in ectopia are greatly predisposed to *cancer*. The coincidence is strking. The surgeon is thus often called upon to treat a degenerated testicle in this position, and the ablation of the diseased organ is the only chance of success. But he is obliged to open the abdominal cavity if the hernia has closely followed the testicle. The inguinal canal is large and gaping; and he almost constantly makes a penetrating wound of the abdomen in seeking to isolate the testicle from the surrounding tissues. The degeneration of the testicle in the external abdominal ring is so much to be feared that it has been proposed to practise the ablation of the *healthy* testicle when arrested in that position, in order to avoid its subsequent cancerous degeneration. I have an observation of a case of this nature concerning a man twenty-seven years of age. The testicle in ectopia moved easily in and out of the abdominal ring. I advised the ablation of the organ, which was in no way diseased, and the operation was successfully performed by my colleague, Monsieur Terrier.

These several observations are extremely rich in pathological deductions. Many writers have contested the influence of traumatisms, irritation, accidental and oft-repeated rubbing or pressure of the testicle, upon the production of neoplasms of this organ. The influence of these causes, however, is strikingly evident when we consider the testicle in three different positions—in the abdominal ring, in the scrotum, and in the abdomen. When permanently occupying the subcutaneous abdominal ring, cancerous degeneration of the testicle is comparatively frequent, occurring in about one-fortieth of the cases; when in the scrotum it is far more *rarely* the seat of cancer, and when in the abdomen it is *never* cancerous. You easily perceive from this statement the influence of the position of the organ upon the production of degeneration, and I am disposed to account for it by invoking the specific causes above mentioned.

Returning now to the operation practised in my two cases, I will explain to you their particularities. The first was a hæmatocele, which I operated upon with the bistoury. At the moment of making the incision I saw a thin sheet of omentum placed before the hematocele between my instrument and the tumor. I resected the omentum. In spite of my multiplied efforts to produce perfect hæmostasis there was a very disquieting hemorrhage from the omentum and the severed arterioles of the sheath, which nearly cost the patient his life, and I feared for the success of the operation, but to-day the cure is established.

My second case was still more complicated. The patient was a gentleman of robust health, vigorous, and of excellent constitution, but afflicted with a sarcocele, a varicocele, and a large hernia, all on the same side. I operated in company with Monsieur Cazin, of Berck-sur-mer. The testicle was first taken away, but by so doing the hernial sac was largely opened. The breach made into the peritoneal cavity was quite vast, and was closed by sutures. But during the same day there occurred incoercible vomiting, and soon other signs of superacute peritonitis manifested themselves. Death occurred on the third or fourth day after the operation, as in cases of penetrating wounds of the abdomen.

To-day I operate on my third case in your presence. We shall take every precaution to avoid a fatal issue. After the ablation of the testicle we shall suture the peritoneum, if opened, just as in ordinary laparotomy, and to this end I have caused to be prepared some silver

wire for sutures, and a straight *chassefil* with which to place them, for we are probably going to cause a loss of substance of the peritoneum.

[After the patient was chloroformed the Professor made a nearly longitudinal incision of eight centimetres in length in the region of the testicle in ectopy, incising the superposed layers until coming upon the testicle itself. He then isolated the testicle and the penis for a distance of two or three centimetres, placing hæmostatic forceps upon bleeding vessels and tying these with catgut, after which the spermatic cord was divided. The hernial sac was not opened, and no sutures were made. The wound was dressed with iodoform, over which was placed a large thick layer of cotton, held in place by an appropriate bandage. The macroscopic examination of the diseased testicle showed a commencing sarcocele.]

Clinical Department

THE CHLOROFORM TREATMENT FOR TAPE-WORM.

Dr. Alfred W. Perry, of San Francisco, reports an obstinate case of tænia lata, successfully treated by the exhibition of chloroform. The patient, a stout man, aged forty, had had a tape-worm for eight years, on which he had tried all the hitherto known remedies. He always vomited the remedy used within half an hour, retaining longest the French capsules of male fern extract. Dr. Perry had made two attempts to dislodge the worm, without success, when he saw the chloroform treatment noticed in The Medical Record. He used it in the following manner, with entire success: The patient was made to fast from 12 M. of the previous day, and only allowed to drink lemonade. At 7 A.M. he took one drachm chloroform in one ounce of mucilage; at 8 A.M. one ounce of ol. ricini. The entire worm passed about 10.30 A.M. The patient was in considerable stupor shortly after taking the chloroform, which stupor lasted three or four hours. He was a large man, weighing one hundred and eighty pounds. Dr. Perry thinks that one drachm of chloroform should not be exceeded as a dose.

ACUTE ATROPHY OF THE LIVER.

Dr. E. Frank Marsh, of Oswego Falls, N. Y., reports a case of the above. On July 25, 1885, he was called to see J. C. M——, a young woman, twenty-one years of age. She is said to have had syphilis, contracted about two years ago.

She complained of nausea, and the vomited matters were very acid and bitter. Bowels flaccid, and no pain or tenderness could be made out. Pulse slightly elevated, and temperature normal. Tongue covered with a white fur. Bowels had not moved in three or four days. Prescribed a cathartic.

The next day she felt so much better that she rode out. About this time her menses came on, and were about normal as to quantity and duration.

July 27th.—Saw patient again; no particular change. Bowels had moved, but not freely. Conjunctiva began to assume a yellow tinge. Prescribed ten grains hydrarg. chlorid. mit. in one-grain doses, one powder to be taken every hour.

July 28th.—Jaundice more marked. Temperature normal, and pulse 85. No tenderness or pain, except a slight headache. There is some desire for food, but it is not well retained. Bowels have not responded to the calomel. Prescribed five improved comp. cath. pills, and five more to be taken the following A.M., if the bowels do not move freely.

July 29th.—Bowels have moved twice slightly. Stools clay-colored. Urine normal in quantity, but very high-colored. Skin decidedly yellow. Patient somewhat weaker; but the desire for food continues. The hands are slightly swollen, but the mother states that such has been the case for two years. Pulse, 90; temperature, 98⅘° F. Prescribed one-half grain podophyllin every three hours.

July 30th.—Jaundice more marked; tongue continues furred, and there is almost constant nausea; the vomited fluid at times stains the clothing green. Prescribed a mixture of chloroform and bismuth.

July 31st.—11 A.M.: There is considerable hebetude; she protrudes her tongue only after being told two or three times, and lets it remain until repeatedly told to put it back. Examined abdomen carefully. No tympanites or tenderness can be made out. Says she is in no pain. Area of hepatic dulness less than normal. Pulse higher, temperature normal, and jaundice intense. 8 P.M.: Patient has been delirious since noon; has not called for any food or drink during the day; but has taken some when offered her. Vomits some. Pulse, 108; temperature normal, and pupils somewhat dilated. Sinapism applied to back of neck.

August 1st.—8 A.M.: The mother says the patient slept quite well from 9 P.M. till 3 A.M. Passed her urine unconsciously. About 7 A.M. she became so wildly delirious that she threw herself from the bed, and at times screamed so loudly as to be heard two blocks distant. Pupils dilated, but respond somewhat to the light. Temperature normal, and pulse 110; respirations, 7, and somewhat sighing in character. By advice of a brother physician Dr. Marsh gave her one ounce of sulphate of soda in solution, part of which was rejected by vomiting. Condition, active delirium alternating with periods of stupor. Pulse, 110; temperature, 98¾°; respirations, 7, and very deep. She takes a little milk. Dr. Marsh was called out of town that evening, and at his request she was seen by Dr. Wells, who found pulse 108; temperature, 98°; respirations, 9. A profuse bilious evacuation has just taken place.

August 2d.—8 A.M.: Respirations, 18; pulse, 90, and irregular; temperature normal. Eyes partly closed; tongue dry, and there is much difficulty in swallowing, which is entirely mechanical. Bowels have moved a number of times during the night, and the discharges were watery and dark. The mother said she had a number of convulsions, after which she passed into a deep stupor. Two hours later: Pulse, 115; respirations, 25. The extremities are warm. 1 P.M.: Pulse, 130; respirations, 43; temperature, 102½°. She gradually sank after this and died about 10 P.M.

Autopsy twelve hours after death. Body appears well nourished. Rigor mortis well marked. Jaundice intense, with marked discoloration of skin in patches over chest, neck, sides, and legs. Liver shrunken, and weighs less than two pounds. Is somewhat mottled in appearance. On section there is a loss of definite structure, and it is ochre-colored in spots, some of them quite large. The cut surface appears granular, and the whole organ is decidedly flaccid. The left lobe is especially small. Gall-bladder partly filled with a dark green gelatinous fluid. Mucous membrane appears normal. The cystic duct, hepatic duct, and common choledoch duct are all open and apparently healthy. The other organs presented no noteworthy lesions.

WORMS IN THE FRONTAL SINUS.

Dr. Albert S. Adler, of Solomonville, A. T., writes that he was called to see an aged Mexican who was suffering from a high fever, pains in the bones, and a very intense pain extending from the hard palate to the forehead, feeling "as if a piece of wood had been forced through." There was hemorrhage from the nose, accompanied with a serous discharge, and lachrymation. These symptoms had come on only a few hours before the man was seen. The axillary temperature was 102° F. The case being supposed to be one of intermittent fever, quinine in full

dose was given. The next morning the temperature had fallen about two degrees, but the pains continued as before. Upon looking closely at him it was seen that the face on either side of the nose was puffy, and this suggested inflammation in the antrum of Highmore. The teeth were sound. The same treatment was continued, cold cloths being applied to the forehead. During the following night from sixty to seventy worms were passed from the nose, and the pain was in consequence much less, being confined now to the frontal region. The worms were about one-half inch in length. Irrigation was then made with solutions of salicylic acid, permanganate of potassium, and corrosive sublimate. No worms escaped while the irrigations were being made, but some came away later. Trephining of the frontal sinus was advised, but the patient would not consent. He later consulted a woman, who gave him a powder to snuff up. Up to the present time he has passed upward of one hundred and fifty worms from the nose; they have now ceased to come away, but there is a constant purulent discharge.

A LARGE NEEDLE SWALLOWED AND PASSED BY AN INFANT.

Dr. Dugan, of Springfield, O., writes that he was recently called to see Carrie F——, aged twenty-two months, whose mother saw her swallow a needle. The mother was sewing, and had placed the threaded needle in the bosom of her dress to use the scissors. Presently she noticed the baby coughing, and turning to discover the cause she saw the thread protruding from the baby's mouth. She made traction on the cord only to let the needle go down. The baby suffered in no way during or since the occurrence. The doctor directed solid food to be given, with the view of conveying the needle through without coming in contact with the intestinal walls. Two days after the accident the child passed a large-sized needle, one and three-eighths inch in length, with sharp point and black in color. It was corroded.

GUN SHOT WOUND OF THE BRAIN—RECOVERY.

Dr. Willis Butterfield, of Belvidere, Ill., reports an interesting case of a little girl, Gertie M——, ten years of age, who was standing talking to a companion, and suddenly sank down to the ground apparently lifeless. Her playmate heard a queer noise, which was the "spud" of the bullet, which struck the girl's head an inch above and behind the right ear. When Dr. Butterfield saw her, a few minutes later, she was wholly unconscious, and on the walk where she fell was a pool of blood containing about a teaspoonful of brain substance. Within half-an-hour an ecchymotic swelling appeared above the eyeball in the outer part of the right orbit. Blood had flowed from the nose immediately after the injury was received. Dr. John Best, of Arlington Heights, was called in consultation. The opening in the skull was round and clean cut on the outside, but splinters of bone could be felt projecting from the inner table. An elastic catheter about the size of the external wound was used for purposes of exploration, as being less likely to injure the sound tissue. This passed about two and a half inches into the brain and pointed in the direction of the right orbit, but the ball could not be detected. On account of the swelling and discoloration about the eye it was thought that the ball had fractured the orbital plate, though no foreign body could be felt in the orbit. The wound was carefully dressed antiseptically, all spiculæ of bone projecting from the inner edge of the cranial wound being removed. The probing and removal of bone fragments caused no pain, but the patient moaned whenever the scalp wound was touched. Two or three hours later the child spoke a few rational words, and the mental faculties were gradually restored during the next few days. The temperature did not at any time rise above 101° F. There was no paralysis, and slight headache was complained of during the first few days only. In three weeks the child was out-doors at play. The right eye remained more prominent than the other, and at times there was double vision. After having made a number of examinations without result, Dr. Butterfield at length discovered the ball in the right orbit, between the inner wall and the globe of the eye. The patient being anæsthetized, an incision was made in the conjunctiva, and a thirty-two calibre ball extracted. The eyesight soon became normal, and the little girl attended school the following autumn with all her mental faculties unimpaired.

SCUTELLARIA LATERIFLORA IN THE TREATMENT OF ENURESIS.

Dr. A. H. Wimermark, of Cambridge, Ill., writes "Having read the excellent article on enuresis, by Dr. Stein, and the remarks of Dr. Willeford upon its treatment by rhus aromatica, I wish to contribute from my store of experience in the treatment of the same difficulty. Some two years ago I was advised by an old practitioner to use fluid extract of skullcap in a case in my own family, and the result was most gratifying. I have since employed it in several cases dependent upon nervous conditions only, and must say that results obtained have always been most satisfactory. A lad, twelve years of age, who would urinate from three to six times every night during his sleep, and had done so for several years, received ʒj. t.i.d. for two weeks, and was speedily and permanently cured. All the cases occurred in children."

Dr. Wimermark advises a trial, at least, of scutellaria when other remedies have failed. He disclaims any credit for originality in the use of the drug, as he says that it was recommended to him by another.

Progress of Medical Science.

Passage of Bacteria from Mother to Fœtus.—An experimental inquiry which may throw light on the relations of the fœtus to the mother in infectious diseases, has been communicated to the Académie des Sciences, by M. Pasteur for M. Koubassoff. The mode of procedure was to inject various cultivations of the bacillus anthracis under the skin of a pregnant guinea-pig. A careful examination of the fœtus was made after the death of the mother. It was found that the bacilli of charbon always pass from the mother to the fœtus; that the longer the time that elapsed between the inoculation of the pregnant mother and her death, the more numerous were the microbes in the fœtus; that more bacilli from virulent cultivations pass over than from an attenuated virus; that pathological conditions of the membranes of the placenta and fœtus hindered the passage of the bacilli from the mother to the fœtus; that inoculation of pregnant females with a too powerful vaccine nearly always caused the death of the fœtus; that inoculation with a virulent virus after the mother had been protected by satisfactory vaccination nearly always killed the fœtus—in other words, the fœtus cannot be protected by maternal vaccination.—*Lancet*, August 1, 1885.

Nasal Polypi and Epilepsy.—To the cases already cited of different forms of reflex epilepsy cured by removal of the exciting cause the following one of Fincke may be added (*Moniteur de la Policlinique*, June 7, 1885). A man, sixty-four years of age, was suddenly seized with numerous and repeated attacks of epilepsy, for which no other possible cause could be found than obstruction of the right nasal fossa by a mass of polypi resembling a bunch of grapes. These polypi were extirpated, and the convulsive attacks at once ceased, and had not returned at the time of the report, two years after the operation.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, August 22, 1885.

PRESCRIPTION ACCIDENTS.

WHEN we consider the immense number of prescriptions that are daily written, it seems remarkable that mistakes occur so seldom. It is certainly to the credit of physicians that poisoning by the accidental misapplication of drugs at their hands is so rare. Continual carefulness is, nevertheless, obligatory on every one, as it is not only the novice who is liable to a chance mistake. There are not a few ways by which a prescription may fail in its mission before or after leaving the druggist. The chirography of professional men is frequently peculiar. We remember once, at a commencement, hearing a learned editor remark encouragingly to the graduating class that he hoped they had learned to read and write. He stated that much of his valuable time was given to deciphering the hieroglyphics of his correspondents, and further commented on the fact that while plain, legible handwriting was a possibility within reach of all, it was actually possessed by comparatively few. In connection with prescriptions the handwriting should be particularly distinct, but we fear that druggists may often have occasion to sympathize with the lament of the editor. It is especially in the writing of symbols that mistakes are liable to occur. A hastily written scruple and drachm may bear such a close resemblance as to escape the commission of a blunder only by chance. An inexcusable source of error is in a lack of sufficient explicitness in the written directions on a prescription. Such vague expressions as "use as directed," "a teaspoonful when required," etc., are direct challenges to accident. Patients find it very difficult to remember directions, and easily become confused in the matter of taking drugs. The metric system is a possible source of accident in the hands of those not thoroughly familiar with its use. A patient in a neighboring city lost his life through an error of punctuation in a prescription written in the metric system. Every physician should acquire the habit of carefully reviewing the prescription after it has been written and before allowing it to leave his hands. It is probably not unjust to state that more mistakes in connection with prescriptions are made by druggists than by physicians. With the more careful training that is now being given to graduates in pharmacy, this source of error will be reduced to a minimum. In this connection we cannot fail to notice the custom of counter-prescribing that is more extensively carried on than is supposed by many physicians, and is a fruitful source, not only of serious accidents, but of lesser grades of malpractice. A promising young man in this city lost his life, not many months ago, from a druggist's clerk dispensing morphine by mistake for quinine. The number of deaths in young children from the opium contained in soothing syrups and like nostrums, so often given over druggists' counters, will never be known. Indeed, whenever any drug or combination of drugs is dispensed, there should be a written memorandum made of it by some responsible party. The formula of any mixture used by a physician can be seen at the drug-store where it has been compounded. There should likewise be a law compelling the owners of quack remedies and nostrums to publish the formula on each bottle. This would not only deprive many temperance people of their toddy, but likewise succeed in driving these charlatans from the field. We think it would be to the advantage of physicians, particularly in office-practice, to dispense the pills, triturates, and globules now made in such perfection by many reputable chemists. It is high time for many physicians, as well as the laity, to appreciate the fact that sugar of milk does not mean homœopathy, and that a globule may contain a physiological and yet decidedly effectual dose of a drug.

ANTIPYRESIS.

IT is only within the last quarter of a century and since the introduction of self-registering thermometers, that any precise observations upon the temperature in disease have been possible; and the science of medical thermometry has, therefore, only within comparatively recent times assumed the rank to which it is entitled by reason of its importance clinically, and as an indication for rational therapeutics. The last decade has seen wonderful advances in this direction, and hand in hand with these has proceeded the discovery of many new, and oftentimes most efficacious, antipyretic remedies. Many of these latter are at the same time so-called specifics, not only reducing the temperature, but also curing the disease of which the fever is but one of the manifestations. Quinine and salicylic acid are examples of remedies possessing this double action. Among the latest of the antipyretics which have been used sufficiently to demonstrate their practical utility are kairin, antipyrin, and thallin.

At the fourth German Congress for Internal Medicine, held at Wiesbaden, in April of the present year, a very interesting discussion arose upon this subject, and was participated in by Filehne, Liebermeister, Jacksch, Strümpell, Rossbach, Stintzing, Heubner and others. The general consensus of opinion was in favor of cold bathing as a means of reducing excessively high temperatures, in preference to the exhibition of internal antipyretic agents. It was argued that it was not simply and solely in the elevation of body heat that the danger of fever lay, but that there were many other complications which were equally, or even more, prejudicial to the patient's safety. In typhoid fever, for example, by far the greatest number of deaths resulted from the anatomical changes incident to the disease itself, or from secondary complications not immediately dependent upon the primary cause of the disease, and but comparatively few were directly attributable to hyperpyrexia. Somewhat in the same way as the antiseptic treatment of wounds has for its object the

warding off of complications rather than the acceleration of the reparative process, so the treatment of a continued fever is to be directed chiefly to the prevention of secondary evils rather than to the reduction of temperature alone. From this point of view the internal antipyretics are of little value. They reduce the temperature, it was argued, but they do not always exert a beneficial influence upon the mental condition; indeed, delirium is often increased, the appetite is frequently destroyed, respiration does not become more free, etc. But very different is the action of cool baths; they are truly prophylactic in their effects. But an elevated temperature is not the chief or the only indication for baths. The principal advantage of this mode of treatment is indicated by the effects of the baths upon the nervous system, respiration, the skin, the kidneys, etc. That at the same time the temperature is lowered is perhaps to be regarded as adding to the value of baths, but it is not in this that their chief value consists.

In certain cases, it was acknowledged, there is a very great danger from the excessively high fever, a danger that must be met promptly if death is to be averted. But here, Liebermeister and others contended, recourse should be had at once to baths, for internal antipyretics required time for their action, and if they were first tried and found wanting it might then be too late to derive any benefit from the direct abstraction of heat by cool or cold water.

But the antipyretic drugs were not without their supporters. Antipyrin and thallin were the most favored, kairin being pretty generally discredited by reason of its occasional violent action. Stintzing, of Münich, was among those who spoke most favorably of these remedies. He said that in Münich, antipyrin had been used very extensively in every form of febrile disease, and often with the most strikingly beneficial results. The course of typhoid fever when antipyrin was used was in striking contrast to that under the former methods of treatment. There was no headache, the mind was clear, the patient made no complaint, and his appearance was almost that of a man in perfect health. He thought the reason that some of the other speakers had not seen such favorable results was that they did not exhibit the medicament in sufficiently large doses. In Münich antipyrin was given sometimes in doses of as much as four and one-half drachms per diem, and in general the rule was to give fifteen to thirty grains when the temperature was from 100° F. to 102° F., and when it exceeded 102° F. a dose of thirty to forty-five grains or over was administered. With such doses he often obtained almost complete apyrexia, lasting for a considerable period. Unpleasant effects, such as chills, vomiting, exanthemata, etc., were observed only in a very few instances.

Thallin, also, had lately been extensively employed in the Münich clinic. In doses of four grains it caused a very prompt lowering of temperature, but its effects were not lasting, and within three or four hours the fever had usually attained, or even exceeded, its previous height. Thallin was not so well borne as antipyrin, and as it excited profuse sweating the patients were often considerably weakened.

While it may be true that the most certain and the safest antipyretic is the cool or cold bath, it is not always the most practicable. It necessitates more or less disturbance of the patient, and it is furthermore not always safe, being sometimes followed, even in experienced hands, by most alarming depression. It is also oftentimes impossible, in private practice, to carry out this mode of treatment as it should be carried out in order to be of much value, and we cannot, therefore, afford to discard antipyrin and other internal antipyretics, which, despite their occasional unpleasant effects, are often of inestimable benefit and not to be replaced by any other modes of reducing temperature as yet known to us.

MEDICAL TREATMENT OF UTERINE FIBROIDS.

Dr. Thomas More Madden, in an address delivered recently before the British Gynecological Society, calls attention in a striking and pertinent way to the value of expectancy or of positive medical treatment in dealing with uterine fibro-myomata. Uterine fibroids do not necessarily impair health seriously or cause death; they sometimes spontaneously disappear, are often arrested in their growth, and appear in some instances to respond to medical treatment. Bearing this in mind, there should undoubtedly be a greater conservatism as regards surgical procedures than at present exists.

As illustrating the large view taken by the advocates of oöphorectomy and hysterectomy, we find in Mr. Lawson Tait's "Address on One Thousand Abdominal Sections" a list of 99 cases of removal of uterine appendages for myoma, with 7 deaths; hysterectomy in 54 cases, with 19 deaths; and one enucleation of a myoma, which proved fatal. Thus we have in all 124 completed abdominal operations bearing immediately on our present subject. From the same statistics it may be gathered that Mr. Tait has, moreover, had no less than 30 incomplete operations of this kind, 17 of which were in cases of uterine, or unspecified, but non-ovarian tumors, in which, after the opening of the abdominal cavity, further procedures had to be abandoned. Of these incompleted operations, Mr. Lawson Tait thinks that he "may speak with a certain amount of satisfaction," though from what he derives this contentment we are, with Dr. Madden, at a loss to understand, as his mortality in them was fifty per cent.

As further illustrating the *cacoëthes operandi* prevalent among abdominal sectionists anxious to reach their hundredth or thousandth case, Dr. Madden cites Dr. Savage, who, in reporting upward of a hundred cases of abdominal section undertaken within a year, boasts that he performs this operation in every case which he has "the opportunity of operating on," without "the slightest attempt at the selection of cases, such as choosing the most suitable and rejecting those which did not seem to promise to be successful."

Dr. Keith has recently recorded 38 cases of hysterectomy, with only 3 deaths. In the *American Journal of Obstetrics* Dr. Bigelow has collected, from all available sources, records of 359 similar operations, of which 227 resulted successfully while 132 patients died. With regard to this mortality, greater than one in every three operated on, we may well, says our writer, ask the question, which was suggested to Dr. Keith by his own more successful practice, viz., does a mortality of eight per cent. justify an operation for a disease that, as a rule, has

only a limited active life, that torments simply, and that only for a time, though of itself it rarely kills?

According to Professor Schroeder, any uterine fibromyoma, however extensive or wherever situated, may be removed by laparotomy or partial hysterectomy with the aid of the elastic ligature. Of those on whom Schroeder thus operated, he lost in his first series of cases thirty per cent., and in his second series twenty-two per cent. These numbers are significant and carry their own lesson with them.

As regards oöphorectomy for fibroids, it is certainly true that the exact measure of its usefulness and the proper indications for its employment are far from being satisfactorily established. In actively growing tumors occurring in comparatively young subjects, with profuse hemorrhage, the operation is probably justifiable. But the removal of the ovaries merely for the arrest of hemorrhage consequent on fibromata is not to be countenanced until other and safer methods of checking metrorrhagia have been fully and unsuccessfully employed. Again, Dr. Madden asserts that this operation is not generally advisable in the case of quiescent fibroids largely occupying the abdominal cavity in older patients.

Turning from the subject of hysterectomy, Dr. Madden first discusses other operations, and recommends highly the substitution of enucleation both for sub-mucous and intramural fibroids, or indeed for all fibro-myomata. We are inclined to think that Dr. Madden is very much behind the times, at least so far as American gynecology is concerned, in thus urging the wider adoption of enucleation for fibro-myomata.

As for the medical treatment, Dr. Madden is on the whole disappointing. He believes that by drugs the size of the tumor can often be reduced or its progress in growth arrested, but he evidently is not familiar with all the measures utilized for this purpose by American practitioners. The use of ergot and sulphuric acid, of Dover's powder and gallic acid, the systematic administration of iodide of potassium and hot-water irrigations, in this country the drinking of hot water, combined with a meat diet, the use of clay applications, and of electrolysis are known to the profession, and have been endorsed by good authority as efficacious.

MASSAGE OF THE THORACIC ORGANS.

Mechanical therapeutics has acquired for itself in recent years a settled place in medicine, and its advocates are constantly endeavoring to enlarge its scope and widen the field of its usefulness. In the *Allgemeine Medicinische Central-Zeitung*, No. 20, 1885, Dr. Emil Schlegel reports some cases of pleuritic effusion, in which absorption of the fluid would appear to have been induced or accelerated by repeated blows upon the chest-walls. The closed fist was used, the blows being struck by a motion of ulnar flexion at the wrist-joint, combined with supination of the hand. The ball of the little finger came in contact sharply with the ribs and rebounded, the hand turning back into radial flexion and pronation. About two blows were made in a second, or six hundred in the space of five minutes. Two sittings were had each day. Under this mode of treatment a successful result was obtained, in some cases in a much shorter period than usual. The author has tried "concussion strokes" (*Erschütterungsschläge*) only in the case of pleuritic effusions, but he believes that it might be equally useful in promoting absorptions in other portions of the body, as the intracranial cavity, spinal canal, etc., which are inaccessible to the ordinary manipulations of massage.

MEDICAL WIT AND HUMOR.

The traditions of medicine are of a grave and sober kind. In the history of our art there is no jest, and in the lives of great physicians of the past there is only a record of serious work. We cannot fancy a smiling Hippocrates—we know that his aphorisms are no "joke;" no one can think of Galen "holding both his sides," and did any great physician from Aracætus to Sydenham leave us a *bon mot*? There have been some things, it is true, handed down to us as great jests. It is recorded as amusing that Dr. Caius in his old age sustained life by suckling a wet nurse! There is a touch of humor in the story of how Erisistratus cured the Prince Antiochus of a wasting passion for his mother-in-law—a type of disease which has now disappeared.

We read in ancient records of a physician, Dr. Hartley, who procured a grant of $25,000 for the secret of a cure for vesical calculus. He took this cure himself until he had consumed therewith two hundred pounds of soap—after and despite which he died of stone in the bladder! In the two hundred years since this record no one till now has thought to ask if the doctor did not have a soap-stone. It was a great philosopher, and a man, we confess, with a large sense of humor, who proposed a "Plan for Extirpating Venereal Disease" which consisted in nothing more or less than in "mercurializing the whole world!"

It may be questioned whether the statue of Taliacotius, nose in hand, may not be classed as a mediæval joke of a permanent and solid character. But the only physician of olden times who has left a record for humor as well as medical skill is Dr. William Butler, who was styled the Æsculapius of his age. It was Butler who ordered a lethargic parson to be put into the warm carcass of a newly-killed cow. One of the choicest specimens of this doctor's old-time humor is recorded in letters from the Bodleian. "A Frenchman came one time from London to Cambridge purposely to see him, whom he made stay two houres for him in his gallery, and then he came out in an old blue gowne. The French gentleman makes him two or three very low bowes downe to the ground; Dr. Butler whippes his legge over his head, and away goes into his chamber, and did not speak with him." Again, "A gent. with a red, ugly, pimpled face came to him for cure. Said the Dr.: 'I must hang you.' So presently he had a device made ready to hang him from a beam in the roome; and when he was e'en almost dead he cuts the veins that fed these pimples, and lett out the ugly black blood, and cured him."

It will probably not be denied that the sense of humor of our medical forefathers was not particularly keen or over-cultivated, though we would not doubt that they cracked their jokes and lived as happily as most people.

But now, forsooth, the sombre mask is being often put aside, and in the place of the staid and learned Hippocrates, we see a smiling philosopher. Of late years there has come to us from Paris and the West a

perennial flow of "Anecdotes Médicales" and works of medical poetry or medical jests. We think that perhaps the matter is being a little over-done. There is no doubt a large craving for the amusing, but the taste still needs a little cultivating. It is surprising to observe the extensive travels of some feeble and rachitic little jest through the pages of medical periodicals. And, like the body, it renews itself every seven years. We have been criticised for intimating that there is no wit in medicine. This is putting it more comprehensively than we intended; but certainly the popular and persistent itineracy of medical Joe Millerism, and the dreary average of works illustrating medical humor, justify in large measure our estimate.

News of the Week.

History of the Vermont Medical College.—Mr. Henry S. Dana, Woodstock, Vt., who is writing a history of the Vermont Medical College, or "Clinical School of Medicine," as it was first called, would like to borrow a copy of any of the catalogues of the Clinical School of Medicine, or Vermont Medical College, from 1830 to 1839; also, a copy of Rev. Mr. Parker's "Sketch of the Life of Dr. David Palmer," delivered in lecture term, 1841.

The Lehigh Valley Medical Association.—The fifth annual meeting of this society took place at Quakertown, Pa., on Wednesday, August 19th.

Texas Physicians and the International Congress.—At a special meeting of the Dallas County Medical Society, on July 25, 1885, the following preamble and resolutions were unanimously adopted with reference to the recent action of the American Medical Association at New Orleans.

Whereas, The American Medical Association at its meeting in Washington City, in May, 1884, recognized a general desire of the medical profession of the United States, by adopting a resolution under which a committee was appointed, whose duty it should be to extend an invitation to the International Medical Congress, shortly to assemble at Copenhagen, to hold its next meeting in 1887 at Washington City; and

Whereas, The said committee, by the letter and spirit of this resolution, was fully empowered to act, not only as a committee of invitation, but as an executive committee as well; and

Whereas, The said committee, in pursuance of the objects of the above-mentioned resolution, and duly exercising the unlimited authority delegated to it, enlarged its membership and otherwise provided for the successful holding of an International Medical Congress at Washington City in 1887, all of which arrangements were considered by us as judicious and, contrary to what has been charged by some, wholly disinterested as to personal or local aggrandizement; and

Whereas, The American Medical Association, at its last meeting at New Orleans, did, in our judgment unwisely and untimely, virtually rescind its former action, which reactionary movement has deranged, if not indefinitely suspended, the work of the original committee, which was satisfactorily progressing, and created an indifference to the Congress among the recognized leaders of medical thought and interest throughout the country; and

Whereas, There are those who persist in urging the so-called justice of their claims for an organization of the International Medical Congress on a territorial basis, which unfortunate idea has been unwisely further extended by some members of the profession in Texas, in a manner calculated to arouse a sectional prejudice, which has little, if any, existence in our State; therefore,

Be it resolved, That the Dallas County Medical Society deplores what must be considered the present interregnum in the affairs of the contemplated International Medical Congress, brought about, as we believe, by an ill-considered and hasty action of the American Medical Association, at the New Orleans meeting before mentioned: that this Society was fully satisfied with the work of the original committee, which was composed of able, eminent, and conscientious members of the profession; that this Society repudiates any attempt to inject a sectional feeling into a purely professional matter, which has reference to scientific investigations only, and that said attempt, if offered in behalf of the medical profession of Texas, is, in the opinion of this Society, both unauthorized and gratuitous, and that, looking beyond a narrow-minded policy of personal aggrandizement and sectional interest, we heartily commend the recent action of Philadelphia and New York brethren, as well as those elsewhere, who have retired from the Congress until a more dignified and unselfish view of the arrangements can be had; and we pledge them our hearty support and good will in their efforts to advance the interests of the American medical profession in future meetings of International Medical Congresses, where the truly representative medical abilities of our country shall be enlisted, uncontrolled by geographical lines or personal preference.

Goodwin E. Peters, M.D.,
Secretary.

Pessaries.—Dr. Samuel W. Francis says that pessary came originally from the Latin *malus—pejor—pessimus!*

The Patient not Dead when Dr. Dudley left Him.—Dr. A. Palmer Dudley, of this city, writes: "In The Medical Record of August 8th, page 163, Dr. John F. Ridlon, in the report of a case of thrombosis of the left coronary artery, makes use of these words: 'At about 3 P.M. the patient's heart stopped, and Dr. Dudley, believing him dead, left him. A few moments later, however, he revived, and was seen by another physician.' This is not correct. The simple facts in the case are these: I did conduct the man to his home and placed him in bed. I stepped from the room for a few moments, and on my return found him with heart and respiration ceased and features cyanotic; by artificial respiration I succeeded in resuscitating him, and half an hour after, under a hypodermic injection of morphia, left him very comfortable."

Medical Congress at Anvers.—The sixth annual reunion of Belgian physicians will take place this month at Anvers, on the occasion of the industrial exposition to be held there. The following question is the one which will form the chief subject of deliberation: "What

are, in the present state of epidemiology, the most practical measures of international prophylaxis which can be adopted, especially in Belgium, against pestilential diseases?"

In Memory of Dr. Panum.—A committee has been organized in Copenhagen to solicit subscriptions for the foundation of a memorial to the late Dr. Panum, whose death occurred on May 2d of the present year. It is proposed by the committee to obtain a bust of the deceased professor, to be placed in the lecture-room of the physiological laboratory. In the committee's appeal, published in the *Hospitals-Tidende*, it is stated that subscriptions may be sent to any of the members, or to Jacob Lund, Kronprinsensgade, No. 7 K, Copenhagen, Denmark.

A Bust of Thullier, the member of the French cholera mission to Egypt in 1883, who died of the disease, contracted while in the discharge of his duties, has been placed in the hall of the superior *école normale*.

Correction.—Dr. Wm. Manlius Smith, of Syracuse, N. Y., writes that he was not the author of the report on infection from imported rags, made at the recent meeting of the New York State Board of Health (The Medical Record, August 15th, page 185). The Health Officer of the port of New York, Dr. Wm. M. Smith, formerly of Angelica, Alleghany County, is the gentleman who made the report.

The Sanitary Condition of the Isthmus.—It appears that Colon is in a terrible way, and a perfect plague seems to have stricken the place. There are sometimes as many as twenty-five deaths per day. The population is less than ten thousand. Mr. Ackerly, the roadmaster of the Panama Railroad, died on July 23d, of hemorrhagic malarial fever. He was ill but forty-eight hours. The French consul, Mr. Paul Savelli, died of yellow fever. Several canal employees died from yellow fever, and about fifty deaths from this disease have been recorded during one month. It must be borne in mind that the terrible condition of the Isthmus just now is directly traceable to the absolute neglect of all the principles of sanitation.

The Congo Dangerous for Europeans.—An interview with a member of the International Congo Commission confirms the statement that fifty per cent. of the European employees in the Congo region have died.

In Favor of Cremation.—Nearly one hundred citizens of Los Angeles have given their names to a committee favoring the organization of a cremation association there, and the immediate erection of a crematory. Sacramento, more than Los Angeles, needs such sanitary reform. Her situation is such that cremation should be specially favored by her people, and burial discarded. From Paris comes the report that the Prefect of Police concurs with the decision of the municipal authorities favoring the cremation of dissected bodies from the hospitals, on the ground not only of economy, but that such a course will relieve the crowded cemeteries.

A Fever Hospital for Sydney, Australia.—The epidemic of typhoid fever in Sydney and the suburbs is on the increase, and is causing a good deal of uneasiness. At a recent meeting of the Directors of the Prince Alfred Hospital, Sydney, a letter was read from the secretary of the medical board, giving reasons for considering it necessary that the admission of typhoid cases should not exceed one-quarter of the number of patients in the medical wards of the institution. The proceedings that have arisen out of this question are to be brought under the notice of the Government, with a strong recommendation from the board as to the establishment of a fever hospital.

Koch's Successor in the Imperial Board of Health.—On assuming the chair of hygiene at the University of Berlin, Koch resigned as active member of the German Imperial Board of Health. He remains an "extraordinary" member of the board, however. Dr. Gaffky has been appointed in his place, and assumes charge of the department devoted to bacteriology.

Physicians on Russian Railways.—The *Vratch* states that the Orel-Vitebski railway has arranged that one of the guards of each train shall be a *Feldsher* (hospital sergeant), and shall wear a badge indicating his profession.

The Bradshawe Lecture was delivered by Dr. Goodhart at the Royal College of Physicians on August 18th. The subject was "Morbid Arterial Tension: a Review."

A Medical Squabble in New Zealand.—The Colonial Secretary having issued a new regulation, the object of which is stated to be to prevent a certain hospital being filled up with cases which should not be sent to it, the medical men connected with the institution consider themselves insulted, and demand the withdrawal of the insinuation.

Deaths of German and Austrian Professors.—Dr. Hermann V. Boeck, Professor of Pharmacology in Munich, has died at the age of forty-two. From Vienna the death is announced of Professor H. W. Reichardt. It is stated that he committed suicide by hanging himself in a fit of temporary insanity. He was fifty years old. Dr. Faludy, the well-known physician for children's diseases, died at Buda-Pesth, aged forty-six.

A Memorial to Pacini.—We learn from the *British Medical Journal*, August 8, 1885, that a committee has been formed at Florence for the purpose of collecting funds for a memorial to the late Professor Pacini. It has issued a circular which contains the following statement: "Honor to the memory of a great citizen, destined to remind posterity of his virtues and his labors, is a duty which the nation that gave him birth is bound to discharge. From such men proceeds an example which acts as a noble oration, preaching great deeds to future generations. Italy has such a duty to perform in memory of Philip Pacini, who discovered the tactile corpuscles, who, since 1854, has devoted himself to profound and original researches on the specific nature of Asiatic cholera, and who has introduced a method of artificial respiration which repeated experiments have proved to be the best for saving life. It is for Italians, then, to perpetuate the fame of this man, who, springing from a humble origin, has succeeded, by force of will, in gaining universal renown in anatomy and biology; who, after a life of exemplary activity, in the course of which he never

thought of his own interests, but rather considered the welfare of humanity, died poor, leaving to his successors nought but certain precious documents of high merit, such as the 'Structure of the Retina,' 'The Electrical Organ of the Gymnotus,' and 'The Extra-vascular Circulation of the Blood.'" The subscribers to the memorial will be informed of its nature, which will be decided upon when the entire subscriptions are received. The Committee consists of Professor G. Pellizzari, President; Dr. Aurelio Bianchi, Cavalier Dr. Luigi Billi, Cavalier Antonio Civelli, Cavalier Dr. P. Cresci-Carbonai, Cavalier Dr. Cosimo Franceschi, Cavalier Dr. C. Frascani, Dr. L. Giuntoli, Dr. G. Marcacci, Dr. F. Settimelli, Professor A. Tafani, Professor A. Targioni-Tozzetti, Professor Pasquale Villari, Senator; Dr. Carlo Stacchini, Signor Olinto Squarcialupi, Secretaries.

The Hospital at Port Said.—The Gordon Memorial Hospital has been abandoned, but the Port Said Hospital has been materially improved; it has been retiled, whitewashed, ventilated, and otherwise rendered cleaner and more habitable. Latrines will be erected so soon as it is determined whether the dry-earth system or the pneumatic cart should be adopted.

The Cholera.—There appears to be little or no abatement in the ravages of the cholera in Spain. It is impossible to obtain accurate figures, but its daily mortality is little short of 1,800, with an average of new cases amounting to over 4,000.

In Marseilles the epidemic appears to be still on the increase. Twenty-seven deaths from cholera were reported on August 18th. Since the 10th inst. 130 patients have been admitted to the Pharo Hospital, 55 have died, and 10 have been dismissed; 65 remain in the hospital. Twelve deaths occurred in Salon, one in Aubagne on the 18th inst. Several fatal cases have also occurred at Toulon. A letter from Saignon reports that 600 French soldiers have died of cholera in Formosa and the Pescadores; that the hospitals are overflowing with sufferers, and that the epidemic is increasing. In Paris active preparations are on foot to exclude the dreaded scourge.

Dr. Reichard the Explorer Reported Dead.—Advices from Zanzibar state that Dr. Reichard, the sole survivor of the German international exploring expedition, is reported to have been killed while fighting the natives during the progress of the Ugogo expedition.

An International Pharmacopœia.—The German, French, and American Pharmacopœias have all been recently issued in a thoroughly revised form. The Belgian Pharmacopœia is just out, and the British Dispensatory is soon to follow. It is hoped that it will appear before the International Convention, called to consider the feasibility of establishing a universal Dispensatory, will have been held.

Professor Gussenbauer's Act of Charity.—The well-known Professor of Surgery at Prague, Dr. Gussenbauer, casually met a medical student about to enter his lecture-room. The professor was struck with the pallid appearance of the student. Questioned if he were ill, the student gave no definite reply. Gussenbauer asked him to step into an adjoining room, and having ascertained that one of his lungs was considerably damaged, advised the student to proceed without delay to some Alpine health resort. The student sadly answered that this would be an impossibility, since he was constrained to support himself by teaching. The professor then told him to call at his house on the following day. There he was handed an envelope containing a one-thousand "gulden" note, and a "bon voyage" from the generous professor.

The Sixteenth Annual Meeting of the German Anthropological Society was held at Carlsruhe, from August 6th to 8th. Wagner, Ranke, Virchow, Waldeyer, Rüdinger, Bissenger, V. Torök, and Mr. Henry Schliemann participated in the proceedings.

Death of Dr. Bowling.—Dr. W. K. Bowling, one of the ex-Presidents of the American Medical Association, and one of the most eminent members of the profession in the Mississippi Valley, died at his residence on Cumberland Mountain, near Nashville, Tenn., on August 6, 1885. He was seventy-seven years of age.

A Hopeful View of the Congress.—The *Journal of the American Medical Association* enjoys the prerogative of being almost alone in its optimistic forecast of the prospects of the International Medical Congress. In its issue of August 15th, it says editorially: "Evidences are not wanting that the principal performers in the great comic play of "Much Ado About Nothing," which was commenced so brilliantly on June 29th by twenty-eight members of the profession in Philadelphia, are becoming weary of their work. Some who were induced to join in the play from the first impulse have already withdrawn, and others are evidently preparing to follow. Dr. John H. Packard, who was appointed Secretary-General of the Congress by the Committee of Arrangements at the meeting in Chicago, and whose name was published as one of the twenty-eight who declined to accept any place in the revised organization, has recently withdrawn his declination and accepted the position. As an offset to the other twenty-seven who started the scheme of obstruction and factious opposition in that city, we have the names of seventy prominent members of the profession in the same city who have freely endorsed the action of the American Medical Association, and pledged their support to the organization of the International Medical Congress of 1887. Among them are the names of teachers and authors as eminent and as well-known both in this country and in Europe, as any of those who so hastily declined. To the same endorsement and pledge are appended the names of several hundred prominent and well-known members of the profession in other parts of the State of Pennsylvania. . . . The idea that the Committee of Arrangements will not be able to complete the work of preliminary organization at its coming meeting on September 3d, or that the vacancies in the several sections cannot be filled with men of the highest standing and ability, is simply absurd." *Nous verrons*, is the only comment we can offer on the above.

Dr. John Ten Brook, of Paris, Edgar County, Ill., one of the oldest practitioners in the State, died at his residence, on August, 8, 1885, aged seventy-seven years.

Death of Dr. William Gaston Bulloch.—Dr. Bulloch died recently in Savannah, Ga., in the seventy-first

year of his age. He was the son of John Irvine Bulloch, and great-grandson of Governor Archibald Bulloch, of Revolutionary fame. After obtaining his degree he went to Europe to further prosecute his professional studies, the greater part of his time being spent in the hospitals of Paris. He then returned to the United States, and settled in practice in his native city. He was President of the Medical Association of Savannah, and also, at one time, of the Georgia State Medical Association. He became a member of the American Medical Association in 1851. He was one of the founders of the Savannah Medical College. He was a surgeon in the Confederate army during the late civil war, was alderman of Savannah for two years, and was physician to the city jail from 1877 to the time of his death.

The Baly Medal, presented by the Royal College of Physicians of London, has been awarded to Mr. W. Kitchen Parker, F.R.S.

Vivisection in Austria.—A movement is on foot in Austria to abolish or restrict vivisection through a governmental decree. The chances do not appear to favor the sentimental anti-vivisectionists.

Professor Huxley.—It is announced that Professor Huxley, F.R.S., has agreed, at the request of the Committee of Council on Education, to continue to act as Dean of the Normal School of Science and Royal School of Mines at South Kensington, and also to be responsible for the general direction of the biological instruction therein.

A New Mydriatic Alkaloid.—M. Crouzel has isolated a body having all the properties of an alkaloid from the mandrake (Mandragora officinalis). This body forms a sulphate which is crystalline. A solution of this salt was found to have marked mydriatic effects on the eye of a rabbit.

Death of Professor Schlager.—Professor Ludwig Schlager, Director of the Wiener Landes-Irrenanstalt, one of the most distinguished alienists in Austria, died at Gastein on the 24th ult. He was fifty-seven years of age.

Calves' Vaccine not Liable to Communicate Tuberculosis.—M. Straus finds that the proportion of tuberculous calves does not reach 1 in 100,000. So the danger of tuberculosis in obtaining vaccine from these animals is practically nil.

A Tape-worm in a Lamb.—An Oregon farmer recently killed a lamb. Through an accident he cut a hole in the intestines, when he saw a tape-worm protruding. He extracted it and found it over thirty feet in length. It must be quite exceptional for a tænia to find a lamb a congenial host.

For the Cure of Corns.—M. Vigier recommends the following: Salicylic acid, 15 grains; alcoholic extract of cannabis indica, 7½ grains; alcohol (90°), 15 minims; ether (62°), 37½ minims; flexible collodion, 75 minims. Mix and preserve in a closely corked vial. The corn is to be painted thoroughly with this mixture every second day for a week. At the end of this time, it is said, the corn can be readily expressed by pressure of the fingers.

Reviews and Notices.

A Text-book of Medical Physics for the Use of Students and Practitioners of Medicine. By John C. Draper, M.D., LL.D., Professor of Physics and Chemistry in the Medical Department of the University of New York. Pp. 733. Philadelphia: Lea Brothers & Co., 1885.

The author regrets in his preface that the study of physics has been regarded in this country as of so little importance in the curriculum of medical study. He regards our educational literature as sadly deficient in this respect. Hence he has been led to place before the public the substance of his lectures in this department of science, delivered during many years at the University of the City of New York.

That this work will greatly facilitate the study of medical physics is apparent upon even a mere cursory examination. It is marked by that scientific accuracy which always characterizes Dr. Draper's writings.

Its peculiar value lies in the fact that it is written from the standpoint of the medical man. Hence much is omitted that appears in a mere treatise on physical science, while much is inserted of peculiar value to the physician. Of special value are the chapters on Physiological and Therapeutical Effects of Variations in Density of Air, and Electro-biology. An interesting section is inserted on Ultra-gaseous or Radiant Matter. Included in the section on the Microscope are full directions for hardening tissues, cutting sections, staining, injecting, etc.

On the Wasting Diseases of Infants and Children. By Eustace Smith, M.D., London. Fourth Edition. New York: William Wood & Co. 1885. Wood's Library of Standard Medical Authors.

The fourth edition of Dr. Smith's work is but little changed from the third, which latter, however, was, at the time of its publication, largely recast and rewritten. The wasting diseases of children described by our author are simple atrophy, chronic diarrhœa, chronic vomiting, rickets, inherited syphilis, mucous disease, worms, chronic pulmonary phthisis, and caseation of lymphatic glands. The separation of these conditions into special classes is necessarily somewhat arbitrary, but we feel no desire to complain since it has some practical value. Dr. Smith prefaces his work with the usual discourse upon infant hygiene and infant feeding. His remarks are sensible and judicious, though he perhaps lays less stress upon artificial feeding than its widespread practice demands. At the close of his work is a chapter on the diet of children in health and disease. This contains many tables, and will be found very useful for reference. These tables, however, might very well be improved by the addition of articles in use in this country. The "Mucous Disease," to which a chapter is devoted, is a new thing in nosology, and is, we believe, the child of Dr. Smith. It is a hypersecretion of mucus from the alimentary tract, occurring especially after whooping-cough and at the second dentition. Unquestionably it is a clinical entity, and our author's description of it deserves attention. The chapters on the other wasting diseases, of which we have given a list, are all profitable reading, and we can heartily commend the book as a most useful one, and as having the virtue also of not being voluminous or dry.

Comforting News for the Small Boy.—Dr. Zulinski, of Warsaw, has been conducting a series of experiments on men and the lower animals to determine the effects of tobacco-smoke upon the system. He found that it was poisonous when inhaled in sufficient quantity, but states that cigarette smokers absorb less of the injurious principles than do cigar-smokers, and pipe-smokers least of all.

Reports of Societies.

British Medical Association.

FIFTY-THIRD ANNUAL MEETING.

Held at Cardiff, on Tuesday, Wednesday, Thursday, and Friday, July 28, 29, 30, and 31, 1885.

REPORTS OF SECTIONS.

SECTION OF OBSTETRIC MEDICINE.

WEDNESDAY, JULY 29TH—FIRST DAY.

DR. GERVIS, President, in the Chair.

This Section has been of even greater interest than usual. Several important subjects have been discussed, great interest has been manifested in the discussions, and a larger proportion than usual of leaders in obstetric science and practice have been present.

After the delivery of the Presidential address the first paper taken was

ON THE OCCASIONAL LATENCY AND INSIDIOUSNESS OF GRAVE SYMPTOMS IN CONNECTION WITH THE PUERPERAL STATE,

by DR. W. O. PRIESTLEY, of London. Dr. Priestley said serious disease, when occurring after delivery usually showed itself within ten days after the day of confinement. Relying on this, in maternity hospitals, women were allowed to leave in ten or fourteen days. But more tedious cases occurred. He related a case in which in a young wife the uterus did not contract well after delivery. The patient, however, appeared to progress favorably and was on the sofa by the eleventh day. Soon after she was allowed to leave the room and go into the adjoining one. On the twentieth day vomiting came on, and by the third week she was unable to put her feet to the ground. There were pains in the limbs, swelling of the joints, and general symptoms of acute rheumatism. There was nausea, indigestion, and the breasts swelled. The temperature was high and the pulse accelerated. The abdomen was tympanitic. This case occured some years ago. Several other physicians saw the case, among these were Dr. Playfair, and the late Sir James Simpson, who came from Edinburgh for the purpose. The patient died thirty-eight days after delivery. In a second case, Dr. Priestley attended and took leave of the patient at the end of the month, convalescence being apparently complete. In a few days he was called in again, and finding the patient not so well advised her to go out of town. Serious eye mischief came on and one eyeball suppurated and burst, with, of course, total loss of sight in that eye. The patient slowly recovered. A third case was that of a young married lady, aged twenty-three, whom he attended in October, 1875, when she was delivered of her second child; forceps were used; the uterus contracted well and it was observed that there was but little hemorrhage. In a few days, however, it was observed that the womb was again large. There was no tenderness on pressure, and no fever or general symptoms. In a few days the patient complained of pain, and one day a sharp pain suddenly came on in the calf of one leg. A phlegmonous swelling formed, in which fluctuation could after a time be distinguished. The late Mr. Campbell de Morgan saw the patient in consultation with Dr. Priestley. When the presence of pus was established, Mr. Morgan incised the swelling and a considerable quantity of pus escaped. In a fourth case the patient was, at the time of her confinement, in rather a poor state of health. She had sustained a great grief a few months previously by the death of her mother. This had made her melancholy and indisposed to take exercise. The labor lasted forty-eight hours. There was fair contraction of the uterus, but dilatation followed. The patient complained of a sharp pain in the chest and pains down one thigh. A poultice was applied to the chest, and quinine given internally. These symptoms were relieved, but three weeks after delivery the uterus was, on palpation, found to be still larger. At the end of the month, the only symptom of which the patient complained was recurring neuralgia. At the end of the fifth week she suddenly felt very faint one day. This passed off, but in a few days she was out and got her feet wet. In the seventh week the patient was attacked with agonizing pain in the right groin. On examination, a swelling was found in the right iliac region. The pulse was 120, temperature 103° F., and the urine was loaded with urates. Pains in the ankles followed; then the wrists became involved. The hands and wrists were kept wrapped up in cotton-wool; there was a curious metastasis from one to the other; sometimes one hand could be moved and sometimes the other. This condition lasted a week; the patient then complained of a pain in the left side of the chest; she was then seen by Sir William Jenner. Pleurisy came on; in the left chest there was complete dulness and absence of breath-sounds; opium was given and adequate doses of bark and nitro-hydrochloric acid were also given; stimulants were also administered; the pelvic swelling receded somewhat; the temperature varied between 104° and 105° F.; the pulse was extremely rapid, being in fact uncountable. Dr. Priestley said Sir William Jenner said it was "an awful pulse." The abscess finally burst spontaneously. Commenting on these four cases which he had narrated as examples, Dr. Priestley said the form of the disease varied much in different cases. Thrombosis and embolism were, he said, especially dangerous. Often only "rheumatic" symptoms were complained of, and in cases where general symptoms occurred they had often been put down as hysterical. The danger to the patient was obvious. Passing on to discuss the nature of the disease, Dr. Priestley said the question was whether there was more than one poison, or whether there was but one, and the varying effects in different cases depended upon the dose. He referred to Pasteur's view of a puerperal germ. Passing on to the question of treatment, he said, the practical point was to recognize the nature of these obscure cases. An important point was to secure due contraction of the uterus, as in many of these cases the uterus had been observed to be large; clots should be removed as they form by pressure or other means; a rigor should never be disregarded; the occurrence of any, even flitting or transient rheumatic pains in the bones or joints should be carefully noted; if no other organ be affected the heart should be carefully examined, as the occurrence of a valvular murmur may be of the greatest significance; any rise of temperature should be carefully watched. Dr. Priestley said that patients who lead inactive lives during pregnancy are more prone to puerperal affections. As germs only find an easy entrance into the system when the latter is in an unhealthy state, we can prevent bad effects from them by improving the general health and thus rendering them less active.

DR. GERVIS, of London, President of the Section, said he had seen similar cases to those related by Dr. Priestley; he had also seen less severe ones. He had often seen patients two or three weeks after delivery in whom there was no abdominal tenderness, but often simply dyspepsia and disinclination for food. On vaginal examination—and one should always be made in such cases—a considerable amount of parametric swelling was often found.

DR. EDIS, of London, said patients should be more carefully watched during the puerperal period. The practitioner should not rush hastily into the room, ask the patient how she is and how the baby is, and go away. A temperature-chart should be taken to the house, and systematic observations made and recorded. We might, he said, save many patients by attention to trivial details. A rigor should be noted, but we must remember that in a weakly patient it might be simply the expression of severe nervous shock. He had seen

similar cases to those of Dr. Priestley, who, he remarked, had travelled over a wide field in his paper.

Dr. Grigg, of London, referred to the former unsanitary condition of Queen Charlotte's Lying-in Hospital, to which he is physician. Formerly the windows were kept closed, and the patients were always afraid of catching cold, and often complained of pains. The ventilation is now much improved, as are also the general sanitary arrangements of the building. Referring to Dr. Priestley's remark, that patients who will not take sufficient exercise during their pregnancy are more liable to be attacked with puerperal disease, he made the suggestion whether this condition might not be due to want of air. He referred to a case in which the temperature rose and fell, and in which exacerbations of temperature were always accompanied by hysterical emotion.

Dr. Wilson, of Baltimore, said that when all went on well for ten days, and then the patient languishes, we have, in a large proportion of cases, one of two conditions present, viz.: 1, relaxed uterus; 2, pelvic cellulitis. Nothing was so important as to watch the condition of the uterus. Ergot and quinine were useful to secure its contraction. Injections could be employed if necessary, and if there was any offensive smell. Opium and hot injections might be employed in cellulitis.

Dr. Chalmers, of London, said this condition was not so much due to a poison from without as to the state of the mother herself. There was no need to go to bacteria. The involution of the uterus itself and the giving off into the general system of a large amount of waste material was sufficient. It was known that the lochia when inserted into an animal caused severe symptoms. Provision was made for getting rid of the lochia, and thus normally no bad effects resulted from them.

Dr. Steel, of Abergavenny, considered that sufficient stress had not been laid upon embolism as a cause of puerperal affections, and referred to the experiments of Cruveilhier which, he said, he had repeated some years ago.

Dr. Priestley, in reply, thanked the members present for the attention with which they had listened to his paper. His object, he said, had been attained if he had secured more attention being paid to minute details. Progress in science showed that no ferments were formed in the blood, but that they were wafted in from without. The more we knew the less were we inclined to believe in autogenetic infection. It did not follow that the germs entered at the time of the illness. They might have been wafted in before, and not developed until the health of the patient became enfeebled. Hence the importance of maintaining a good state of the general health.

The next paper was

ON ANTISEPTIC MIDWIFERY AS CONDUCTED IN A LYING-IN HOSPITAL,

by Dr. W. C. Grigg, of London. The hospital to which the paper referred was Queen Charlotte's Lying-in Hospital. Dr. Grigg said that the result of the introduction of antiseptics into that hospital had been that as low a mortality had been attained as in private practice. Antiseptics were therefore as efficient in obstetric as in surgical practice. Maternity hospitals had been decried and called slaughter-houses. It had, however, been shown that they could be maintained and midwives and medical students trained in them. Maternity hospitals were really the pioneers of hospital sanitation. Queen Charlotte's Hospital was built in 1752, rebuilt in 1856, and the new building opened in 1857. About five hundred patients were admitted annually, being an average of forty-two per month. The wards were sixteen feet square and twelve feet high. There was no cross ventilation. The air-space for each patient was about seven hundred cubic feet. The floors were only of deal, but they had lately received a coat of lacquer. In 1879 an outbreak of puerperal fever occurred, and the hospital was closed for five months, being reopened very curiously on the same date at which two other maternity hospitals which had been closed were also reopened. The hospital has never been closed since. Formerly it was always closed one month every year for the purpose of being cleaned. Before being reopened many sanitary improvements had been effected. The water-closets and drain-pipes were now outside and were thoroughly ventilated.

Since the rebuilding of the hospital in 1856 there had been 12,500 women delivered in it. Of these, 5,000 were married or widows, 7,500 were single. Of these, 276 had died, and 200 of these were single women. Since the introduction of antiseptics (within the last few years), this mortality had been much lessened. Wood-wool pads and the use of corrosive sublimate as a lotion and injection were introduced in 1884. Dr. Grigg gave some particulars respecting 1,100 cases which had been treated since the introduction of antiseptics. They included many severe cases; sixty might be regarded as serious. Nevertheless, no single case died within the month, and within the year they had had nine hundred cases without a death and without there having been any periodical closure of the hospital for cleansing. Dr. Grigg enumerated the various antiseptic measures employed. The linen was carefully disinfected. In each ward, after it had been used, the following measures were adopted before another patient was brought into it: Four pounds of sulphur were burnt in the ward, the floors were washed with a solution of carbolic acid, and the bedding stoved at a temperature of 250° F. While occupied by patients the wards were wiped out daily with turpentine, washing with water being avoided. The wards were heated in winter by coils of hot-water pipes, but fires in open grates were also kept going. The wards were kept at a temperature of from 52° to 54° F. Carbolized oil (1 in 60) was applied to the fingers before making any examination. The patients were douched with a solution of corrosive sublimate—1 in 2,000—after delivery. (Dr. Grigg said this was the strength of solution he employed himself; his colleague used one double this strength, viz., 1 in 1,000.) After delivery, the patients had administered to them either a wineglassful of vinegar with a drachm or so of tincture of opium added, or else some ergot. He preferred the vinegar and opium to induce uterine contraction; the action of the ergot was less persistent and was gone in twenty minutes. The patient was not removed from the ward in which she was delivered until the uterus was firmly contracted. The perineum was examined, and any lacerations were stitched up at once with a catgut suture and boracic dressing applied. Chloroform was not used except in instrumental labors. The vulva was washed with a solution of corrosive sublimate. A five per cent. solution of carbolic acid was used for washing out all vessels, catheters, etc. The same vaginal tube was never used for two patients. The patients were douched twice a day when the lochia were offensive, but as a rule they were not douched at all unless the temperature was high or abdominal tenderness present. The douche was always left off when the complication ceased. The use of the syringe was avoided; it was dangerous and painful. Dr. Grigg said vaginal or intra-uterine tubes should be of glass, and exhibited a specimen of one he thought suitable for intra uterine medication. They were always kept in a five per cent solution of carbolic acid. When done with in any case, they were boiled and then kept in strong sulphuric acid until again wanted. He thought the action of corrosive sublimate was twofold, viz., 1, that it destroyed germs; 2, that it arrested bleeding from small vessels. He believed it was the only antiseptic which could, without danger, be introduced into the genital tract of sufficient strength to destroy germs.

Dr. Gervis remarked on the value of iodoform pessaries as antiseptic agents. He was not aware who had originated them; he had heard of them from Dr. Champ-

neys. They consisted of one drachm of iodoform made into a pessary with gelatine and starch. They dissolved very slowly, and thus lasted for days. After making an examination, one of these might be left in the vagina, where it would slowly dissolve and give a very good account of any germs which might be present. One might be placed in the uterus also, if wished.

The next paper was

ON THE SEPTIC ORIGIN OF PELVIC INFLAMMATIONS,

by DR. A. E. LAWRENCE, of Bristol. Dr. Lawrence said he was convinced that a large number of pelvic inflammations were due to the absorption of septic material. Why should not the antiseptic resources available for general surgeons be used by him? Out of three thousand cases seen by him, sixty cases of pelvic inflammation had occurred in which there was a definite history of septic absorption having taken place; of these, forty terminated in abscess. He said he used the word pelvic inflammation in its widest sense; it tended to spread and involve various parts. When effusion occurred, the question was whether it was going to be absorbed or break down into pus. The latter usually occurred when the condition was due to septic absorption. Old pelvic inflammations were a frequent cause of adhesions, which prevented the normal movements of the organs. This caused the woman to be conscious that she possessed pelvic organs—a consciousness she was better without. He considered fully one-third of the aches and pains met with in women were due to old pelvic inflammation. We should, he said, try to secure two points after delivery, viz.: 1, cleanness; 2, contraction of the uterus. Dr. Lawrence said he now employed the plan made use of by Dr. Macan, Master of the Rotunda Lying-in Hospital, Dublin. This was the use of pessaries made with cacao butter, and each containing twenty grains of iodoform. This method could be carried out by the nurse, one being inserted after delivery. If any smell persisted in spite of this, he washed out the uterus himself with tincture of iodine and water. He did not approve of leaving the pessary in, and had lately met with a case of pelvic abscess due to the nurse having neglected his instructions on this point. The evening temperature of the patient was 101° for four months, the morning temperature remaining normal. Referring to the practice of dilating the cervix with tents, he said he believed that the deaths which occurred were due to septicæmia. No wonder. After dilatation had been procured, the stinking tent was removed, and the examination then usually made at once. The finger passing up into the uterus carried the septic matter with it. Before examining we should wash out well with iodized water, and thus remove all offensive matter. He preferred sea-tangle or tupelo to sponge tents. Where the latter were made use of they should never be inserted by means of the tent-introducer, but the duck-bill speculum should be used; we could then both see and feel what we were doing, and the tent need not touch any part until it reached the cervix.

The next paper was on

THE DUTY OF CONSULTANT AND PRACTITIONER IN RELATION TO PUERPERAL FEVER,

by DR. W. L. REID, of Glasgow. Dr. Reid said it was a question of what we should do in the matter of antiseptic precautions. Some felt that too much was done; some that too little was attempted. In private practice we could not deliver every woman under the spray and have everything either new or fresh from being disinfected. General practitioners who were in attendance on puerperal women *must* see fever cases. There were three matters to be attended to. These, in the order of importance, were: 1, The hands of the practitioner; 2, his clothes; 3, the hair and body generally. Instruments, etc., must of course be carefully attended to. When he had visited a septic patient what he did was to enter a small room, set the antiseptic spray going, sit down, and read. In about twenty minutes he was saturated. He then put on a fresh suit of clothes, everything being fresh, even to the necktie. The others were hung up out-of-doors for several days. Mere washing the hands was not enough, but an antiseptic should be employed. A good plan before examining was to anoint the hands with a mixture of glycerine and soft soap, containing five per cent. of carbolic acid. This defends the doctor from outside influences and also protected the patient from him. If the patient had to be seen three or four times daily then other midwifery work must be abandoned.

A discussion then took place on the three last papers.

DR. GERVIS spoke of the use of tents. He said he had entirely given up the use of sponge-tents and almost entirely that of sea-tangle ones. It was two years since he had even used one of the latter. He used Hegar's dilators now, which he considered preferable in every way. He kept the patient in bed on her back and washed out the genital tract thoroughly. Iodine vaporized by heat was, he said, a powerful disinfectant.

DR. HAMMOND, of Glasgow, referred to his own experience in Glasgow dispensary work. Among even the very poor a good deal might be done by free ventilation and the use of Calvert's carbolic soap (that containing twenty per cent. of carbolic acid). Good ventilation might be secured by covering the patient up for a few minutes every three or four hours and then opening the doors and windows. Cases will, however, occur such as those described by Dr. Priestley, in which the patient goes on improving, then a rigor occurs, the patient sinks into a weak state, and it is only by the greatest care that she can be brought round. Dr. Hammond said he could only remember one or two cases going on to suppuration. He referred to a septic case in which he was called in consultation and refused to make an examination. The patient was evidently moribund, and he told the friends that to examine could do no good and might lead to his infecting other patients. He saw the local practitioner a few days afterward and told the latter he was not to take offence because he did not examine. The practitioner replied that he wished he had been nervous as well as Dr. Hammond; he had himself examined and had infected the next three patients he attended.

DR. LAWRENCE said he kept a light suit of washable material for use in such cases. After visiting a case he considered septic he went direct to the Turkish bath. He there had a bath and put on the washable suit which he had had sent from home to the baths, and the clothes he had taken off were placed in a bag kept aseptic by means of carbolic acid, taken home, and then disinfected. If he had to attend the patient for three or four days he did not see other cases. If three or four cases were attended very close together in point of time, and one became infectious, it was most unfortunate, as the practitioner had often attended all before hearing of that one's illness. He referred to the danger of dirty hands—one he had seen exemplified. In making an examination it was better to take off the coat and roll up the shirt-sleeves than have a towel pinned round the arm in the elaborate manner in which nurses did it. He remarked that we must distinguish mere local inflammation from septic states; the former did not necessarily prohibit attendance on other patients.

DR. EDIS, of London, spoke of the over-precautions which were thought to be necessary in ordinary cases. He thought it was "antiseptics run mad." We should next hear of "antiseptic conception." In private practice thousands of midwifery cases were attended without any deaths and without the use of antiseptics. Several gentlemen had published in the *British Medical Journal* a roll of more than a thousand cases. He believed, of course, in the use of antiseptics in cases of puerperal fever. The essence of antisepsis was strict cleanliness; you could, he admitted, augment this cleanliness by using antiseptics, but he did not believe that in every case

attended it was necessary to leave an iodoform pessary in the uterus, another in the vagina, apply a wood-wool pad, and envelope the patient in antiseptic gauze.

Dr. Grigg said that any one connected with a maternity hospital must be prepared to forego a considerable amount of private practice. Practitioners would not call such physicians in consultation for fear of infection being conveyed to their patients. His experience, however, had shown that a maternity hospital could be safely conducted. As to infection, he had repeatedly seen the house-surgeon go from case to case, simply rinsing his hands in carbolized water, and with impunity. Precautions were, however, desirable. There was no doubt that the hand might be infected with a poison—whatever it was. He had a large correspondence some time since on this subject with various members of the Association. A very useful recommendation, made by one gentleman who wrote him, was to take to gardening when the hands were infected. A week or two's gardening, by bringing the hands into intimate contact with the earth, would remove all danger of infection from the hands.

Thursday, July 30th—Second Day.

Dr. Gervis, President of the Section, in the Chair.

The work of the Section was commenced on this day by the reading of two papers in French by Professor Lesshaft, of St. Petersburg. The first paper was

on the structure of the pelvis.

The second was

on the influence of mechanical violence on the form of the skull in young animals.

Fresh specimens were exhibited illustrating these two papers. Numerous skeletons of young animals were also shown, showing the modifications caused by exclusive animal and exclusive vegetable diets.

Dr. W. S. Playfair, of London, then introduced a discussion on

the proper sphere of constitutional and topical treatment in certain forms of uterine disease.

This discussion was really inaugurated as a reply to the statements advanced by Dr. Clifford Allbutt in his Gulstonian lectures at the College of Physicians, which have been rankling in the breasts of the gynecologists ever since. Dr. Playfair referred to Dr. Routh's reply to Dr. Playfair, and said that Dr. Routh overstated his case. He then alluded to some of Dr. Allbutt's original statements. Dr. Allbutt, he said, had talked of women becoming entangled in the net of gynecology, had said their uterus was somewhat like their nose, and like that organ was sometimes a little on one side and sometimes ran a little. If the former, it was impaled on a prop; if the latter, it was painted daily with iodine or other caustic, until the fatal arrow of hypochondriasis was at length implanted in the woman. Referring to these phrases, Dr. Playfair said he would repeat what he had stated in Dr. Allbutt's presence, viz., that Dr. Allbutt's admirable mastery of English had led him away into epigrammatic statements. He had partially made the "amende honorable" by saying that he did not apply these remarks to scientific physicians, and had done him (Dr. Playfair) the honor of saying that he excepted him from those whom he accused. It was true, said Dr. Playfair, that he had himself paid great attention to the neurotic element in gynecology, but no one who knew him could accuse him of want of attention to true gynecological work. We had of late years made great advances in diagnosis, pathology, and treatment, *e.g.*, in hæmatocele, cellulitis, etc. Still some diseases were less easily determined than others, and mistakes were common, but he denied that they were due to other causes than want of knowledge and error in judgment. Moreover, there was a danger in underestimating the condition. The pendulum tended to swing to the opposite direction. Some doctors went so far as to tell a woman that she had nothing the matter with her, and send her away for a change and tell her to have nothing to do with the doctors, and this, too, in a plain case susceptible of relief. Errors as to treatment were most frequent in three classes of cases, viz., deviations in the axis of the uterus, endometritis, and (so-called) ulcerations of the cervix. We could not lay down definite rules as to treatment. It was impossible to exaggerate the value of constitutional treatment in uterine diseases. It was not surprising that the general health suffered, and often overshadowed the original disease. It was difficult to combine local treatment with general rest and hygiene. He differed from Dr. Graily Hewitt on the question of deviations of the uterine axis, but he quite agreed with him as to their effect on the general health. We were now passing through an era of flexions. A patient now often asked, "Am I displaced?" They had often been told they were slightly displaced, when in point of fact no diagnosis had been made. It was difficult to imagine how any student of uterine diseases could think flexions were of no importance, as a well-fitting pessary often gave relief. Many cases, though, needed no treatment. When a pessary gave relief, there was no need to make repeated local applications. When such were made it was a great abuse. When a pessary had been applied, two or three subsequent visits were ample, and then there was no need of further treatment for months. What was called ulceration of the cervix was merely abrasion, and when the speculum was first brought in the importance of this affection was exaggerated, and repeated caustic applications were made to the cervix, which could, at the best, have but a temporary effect. In itself this affection was of no importance, and frequent cauterizations were not legitimate under any conditions. Even in endometritis a few applications made within the first few days immediately succeeding one or two menstrual periods were generally sufficient. The gynecologist could not be accused of over-treatment in any other local diseases. *In via media tutissimus ibis* was the safest motto. We must not overestimate the local lesion on the one hand, or the disturbance to the general health on the other. There might be a danger of provoking a neurotic taint. Patients differed very much.

A letter from Dr. Clifford Allbutt was then read. (Dr. Playfair had previously to the meeting submitted his paper to Dr. Allbutt, so that the latter might be prepared to criticise. Dr. Allbutt did not come, but wrote a letter.) Dr. Allbutt said Dr. Playfair had quoted one or two passages from his lectures without taking the context. He had only stated what country practitioners had been muttering for years. He had known cases in which the treatment was co-extensive with the duration of the London season, or with the session at the medical schools. In what works, he asked, were the limitations laid down of which Dr. Playfair approved?

Dr. Gervis said he utterly repudiated the charges made by Dr. Allbutt. As for what the country practitioners were said to have stated, why, he said, in most cases where local treatment was employed it was carried out in conjunction with the local practitioner.

Dr. Edis said Dr. Allbutt had done harm in one way and good in another by saying something to create amusement. The position of the uterus was not the only thing to observe in making a vaginal examination. He thought Dr. Clifford Allbutt had done a mean trick; as a specialist himself he had fouled his own nest. But it was not a personal question. It was a question of our art. A combination of local and constitutional treatment was best.

Dr. Lawrence said that what Dr. Allbutt had stated was true as regards dishonest practitioners. The more we knew of our patients the less local treatment did we employ. He himself made many more local applications to his out-patients than he did to his in-patients, whose

condition he knew better. He said he went further than Dr. Edis as regards vaginal examinations. Dr. Barnes said in his work that we ought to ask ourselves, What are the groups of symptoms calling for a genital examination? He agreed with Dr. Barnes in this. We ought to know what to expect before we examine. There were some cases in which we should never think of sending away the patient without making an examination. In a case, for instance, of hemorrhage in a woman in whom the menses have entirely ceased, we should examine and should expect to find cancer or some other grave lesion.

Dr. Meredith, of Wellington, Somerset, referred to defective sanitary arrangements as a cause of uterine affections. Even a slight leakage of gas in a bedroom had been known by him to cause uterine trouble.

Dr. Imlach, of Liverpool, said if we could not cure by local treatment in fourteen days we had better give up the case. In many cases of flexions there was often disease of the tubes and ovaries as well. It was of no use to treat the flexion in such cases; it was not the real disease.

Dr. Berry Hart, of Edinburgh, said that what we wanted was more exact knowledge of many of these affections.

Dr. Steel, of Abergavenny, said it was no wonder that local treatment was overdone.

Dr. Wilson, of Baltimore, said he endorsed every word that Dr. Playfair had said. He was glad to find British views were in accord with those held on his side of the Atlantic. He urged the importance of exercise. One or two months of local treatment was enough at a time. If patients did not improve in that time he sent them away for a change, or, if they did not go away, he told them to stop away from him for a time.

Dr. Gervis advised the judicious combination of local and constitutional treatment.

Dr. Playfair briefly replied, and the discussion then terminated.

(To be continued.)

SURGICAL SECTION.

Wednesday, July 29th—First Day.

Mr. Harrison, of Liverpool, read a paper (see page 113)

ON BLADDER TUMORS.

Dr. Stein, of New York, recommended bilateral incision of the prostate as a means of exploration of the bladder. He also exhibited an instrument for uniformly dilating the female urethra, in order to remove tumors in the bladder.

Mr. Carr had recently had a very interesting case, which showed the value of operating in tumors of the bladder. A woman had been suffering from hæmorrhage, and was found to have a mass of cauliflower-excrescence in the bladder. This was removed, and the woman made a rapid recovery, which lasted for some years. This Spring, 1885, she had a return of the bleeding. He again dilated the urethra, and found a broad, hard tumor in the bladder. Some of this he enucleated, and some he scraped away with Durham's retractors, and then sponged the parts with iodine and phenol. The woman was now quite well. All this shows that when the growth is malignant even much may be done. Between the two operations on this patient she had given birth to a child. He had no experience in such cases in the male, but quite approved of Dr. Stein's plan of bilateral section of the prostate in such a case.

Dr. Penny, of Bristol Hospital, recommended suprapubic section for the removal of such tumors.

Mr. Humphrey, of Shrewsbury, also approved of Dr. Stein's plans in dilatation of the female urethra.

Mr. Harrison, in his reply, read two letters, just received. In one from Mr. Annandale that gentleman said that every case must be judged on its own merits and carefully explored before undertaking such an operation. Mr. Cage wrote that such bladder tumors were certainly very hopeless cases. Perhaps one in ten might be benefited by operation.

Mr. William Adams, of London, read a paper on

CONGENITAL DISLOCATION OF THE HIP-JOINT.

In 1845 he had seen the first case of the complaint in a boy eighteen years of age. In 1860 more than sixty cases had been observed, thirteen of which had been in males and forty-seven in females. In nineteen cases both hips were affected. In two of the histories the infants were born before the medical man arrived. The affection was in one case said to have been hereditary. No malposition is noticed in the infant at birth, and it was not until it began to walk that the child was noticed to have anything the matter with its joints. In some cases the patient is treated for hip-joint disease. At the age of three years the diagnosis becomes easier by means of Nélaton's lines and the ilio-femoral test. It is said that the head of the femur can be felt in such cases, but he had not found this to be true. Nor is obliquity of the thighs a symptom. Carnochan's original work was published in 1850, and several of the plates there given were drawn from life, or copied from pathological specimens in the Dupuytren Museum of Paris. Mr. Adams put the question: Is this a true dislocation or a malformation of the acetabulum? He was inclined to look on the disease in the latter sense. The acetabulum was not sufficiently developed in the uterus, and the capsular ligament was long and loose in most of the cases.

A paper was read by Dr. Thomas, of Adelaide, on the

TREATMENT OF HYDATID CYSTS OF THE LUNGS BY MEANS OF PUNCTURE.

Such patients, the author said, often exhibit the most advanced symptoms of consumption. In one case the cyst weighed ten ounces, and contained two hundred and fifty-six square inches in superficial extent. There had been thirty-two cases of this disease collected by himself. In the Adelaide Hospital there had been five cases operated on. The general result of the treatment by perforation had been that of twenty-five operated upon five had died. The patients were of all ages, from ten up to fifty years. A cyst under the scapula might be opened by means of a puncture made under the clavicle, and the trocar and cannula might be used. He personally had operated on five cases. Of these four did well and the fifth died. Altogether he made out that twenty-seven cures had arisen from thirty-two operations. Some persons had wished to put forward the idea that all cavities in the lungs should be treated by perforation, but he thought this out of the question in cases of phthisis. Finally, Mr. Thomas showed specimens of the various means taken to arrest hemorrhage after the operation, one of these being a cleverly devised bag resembling the fiddle-bags of Dr. Barnes, and the others india-rubber chest catheters made by Messrs. Mayer & Melzer.

Dr. Ward Cousins referred to the difficulty in the diagnosis of such tumors, and there was danger of inflammation of the sac after opening.

Mr. Thomas said that this was doubtless the case sometimes, but not so when the patient was found to be expectorating large fragments of hydatids. In Australia these cases were frequent enough, and in most cases there was no difficulty in that part of the matter. The operations had been most successful.

Thursday, July 30th—Second Day.

Dr. Bennett in the chair.

Mr. Treves read a paper (see p. 169) on the

TREATMENT OF INTESTINAL OBSTRUCTIONS.

Mr. Lawson Tait, on being called on to speak, explained that he had not heard the paper, and was not able to give any opinion on it, having been in the Obstetrical Section during the reading of the paper.

Dr. George Smith said the best ground for diagnosis of the position of the lesion was only to be learned by visual inspection, not by tactile knowledge. The coils should be seen and, generally speaking, the part that was most inflated would come to the surface and not be very far off from the seat of the stricture. Not that he was at all in favor of any wholesale extrusion of the bowels. The incision should be in the median line, and the finger should be substituted for the hand in ascertaining the seat of the disease. He might say in passing that the bowel might be handled with perfect impunity. Large quantities of fluid in the intestines might cause intestinal obstruction of a physiological kind. Over-distention of the bowel should be avoided. Nélaton's operation for enterotomy was the best, and the best plan was to form for a short term an artificial anus. He confessed that the operation for intestinal obstruction was one of the most difficult in the whole range of operative surgery, and the one which required the greatest care and knowledge of the structures coming before the operator's view.

Mr. A. Eddowes said that occasionally a case of spontaneous cure of intestinal obstruction took place, and gave the clinical history of a case of this kind. The diagnosis should be made as early as possible, and he mentioned a case where a boy had come into the Salop Hospital, in whom a portion of intestine had followed the route of the testis, which lay in an undeveloped condition in the inguinal canal close to the testis. This was found out after death, as the boy died shortly after admission into hospital. That case might have been saved had the diagnosis been clearly made out.

Mr. Robson Mayo said that the record of post-mortem examinations of intestinal obstructions in hospitals showed that many cases could not have been benefited by operation, while others might have been greatly benefited by a timely operation. In the former run of cases there were such as those where purulent peritonitis existed. In one case in which he had operated he had removed nearly two feet of gangrenous intestine, and stitched the divided ends of the bowels together. This patient died the following day. All cases of laparotomy, whether successful or the contrary, should be reported. Out of six cases he had operated on four recovered. Mr. Teale, of Leeds, had collected histories of twenty-one cases, most of which had died. His conclusions were that in chronic intestinal obstructions belladonna would often relieve or cure. Laparotomy as a means of diagnosis and possible treatment was often useful and sometimes might remove the obstruction or at least give some relief. This is one of the most important of all surgical cases, and he believed that, in the same way that ovariotomy had recently come into the sphere of the surgeon, so would the treatment of intestinal obstructions in a short time.

The debate was continued by Mr. Pughe and by Dr. Ward Cousins.

Mr. Pughe then read "A Case of Successful Abdominal Section for Internal Strangulation."

Mr. Bishop Stanmore read a paper on "Enterorraphy, with a Description of a New Form of Suture."

Mr. Edmund Owen read a paper on "Caries of the Cervical Vertebræ."

Dr. Snow read one on the "Non-heredity of Cancer," and Mr. Keetley spoke on the "Radical Cure of Hernia by Injection."

The Section adjourned until 11 A.M. on Friday.

Friday, July 31st—Third Day.

Dr. Bennett in the Chair.

Dr. Bernard Roth read a paper on "Two Hundred Cases of Lateral Curvature of the Spine Without Mechanical Support." The great value of regulated gymnastic exercises was strongly insisted upon by Dr. Roth, who gave a number of cases in which patients had been restored to health by his plans. There was no discussion.

Mr. Brindley James read a paper on the "Treatment of Lumbago and Rheumatic Pains by the Percusso-punctator," in which he recommended the use of galvanism in these painful affections, giving a series of interesting cases.

Dr. C. B. Ball, related a case of "Melanotic Sarcoma of the Rectum," in which he had performed excision of the rectum, with the result that the patient was alive a year after the operation.

Mr. Farrant Fry read an account of cases of the treatment of varices by excision, which he much recommended in many cases.

Mr. Mansell-Moullin read a short paper on "Chronic Sprains."

Mr. T. E. Cahill read a paper on "The Latest Surgical Dressing." After saying that Listerism no longer held sway in Berlin, he spoke of several plans of aseptic dressing still in use in Germany, and wound up by describing a dressing of dried peat which had been heated and dried several times, and was then applied to wounds. This acted evidently, he said, by its astringency not by its asepticity.

Dr. Drysdale, of London, had seen in the surgical practice of Mr. John Wood such admirable results from the antiseptic treatment, that he was very sorry to hear that surgical opinion seemed again to be waning in its belief concerning carbolic acid.

PUBLIC HEALTH SECTION.

Wednesday, July 29th—First Day.

Dr. Davies, in the Chair.

A paper by Dr. Paine, of Cardiff, was read on

CHOLERA AND THE CITY OF CARDIFF.

In the absence of the author, it was read by Dr. Vacher, of Birkenhead. He gave in his adhesion to the germ theory of the disease. It is a specific organism which causes cholera, which may continue latent for a long period, as exemplified in the origin of the cholera in Toulon last year, from stores in an old hulk that had lain by since the Crimean war in 1854. In 1849 cholera first visited Cardiff, in May, when it first occurred in Caroline Street, and in a few days spread through the contiguous streets, where the water-supply was polluted. There were 351 deaths in a population of 16,693. A temporary hospital was erected for cholera patients. After this epidemic a complete system of drainage was established. In 1853 a man came to Cardiff with cholera from Bristol, and was removed to a building near the workhouse. The man in charge took the disease and died in a few days, and also the nurse; but there were no more deaths. In July a foreign seaman with cholera was found in a seaman's lodging-house, in Millicent Street. He died of it, and his infection was traced to a foreign vessel. Two days after this cholera broke out in the street, and deaths took place in the houses adjacent to No. 49, where he died. Thirteen cases arose in two days. Convalescents were removed to the temporary hospital, where each patient remained a few days and was then discharged. No second case occurred in the family thus treated. The use of well-water was prohibited and pure water was used. In 1866 cholera entered Cardiff from the sea, but only 44 died of it. A block of nine houses in Morgan Street was found where one case of cholera occurred. All of these houses were supplied from a pump. Eight of the houses had this supply. Ten cases occurred in the houses. The ninth house had water from a public supply and escaped. In 1884 fear was entertained lest the disease should come to Cardiff from Toulon. A steamer was therefore employed to board all vessels arriving from suspected ports and to put the cholera questions. If any case of cholera was reported on board, the patient was removed to a temporary hospital on the island of Flat Holm, and the

crew carefully inspected. All infected vessels were thoroughly disinfected before being admitted into port, the bilge-water being carefully discharged. Four vessels with infection on board arrived, from which three cases of cholera were removed and treated in hospital. By such care cholera is robbed of its chief terrors.

Dr. Ballard, of London, said the most agreeable feature in the paper read was that no mention was made of the bacillus. Dr. Pringle had followed the line of argument pursued before there was any talk of germs, and he thought the younger members of the profession would do well to look mainly after local conditions for the prevention of cholera.

Mr. Dyke, Medical Officer of Health, at Merthyr, said he had had experience of four outbreaks of cholera in Merthyr, and was ready to express his opinion that the spread of cholera was greatly caused by filth. If filth were removed, cases of cholera would not occur.

Dr. J. Martin, of Weston-super-Mare, gave a description of cholera in two contiguous villages, one healthy and situated on a gravel soil, and the other dependent on a polluted water-supply. The latter was severely attacked.

Dr. Davies praised the immense care of Dr. Paine. There was at present no power to deal with persons on board ships unless they were actually ill. He thought power ought to be given to detain the rest in an infected ship for forty-eight hours, until danger of contagion was over.

Dr. C. R. Drysdale, of London, considered that cholera was as specific a poison as small-pox or syphilis, and that this poison entered the system either through the lungs or by means of a contaminated water-supply. Some persons said it was not taken from the sick, but in the Punjaub, in one epidemic, seven hundred attendants on the sick had taken it. The Broad Street pump was contaminated in 1856 in London, and in ten days five hundred persons were attacked with cholera. Of nineteen persons who drank water contaminated by fresh excretions in one epidemic, five died within forty-eight hours. The disease never appeared in any city unless some person with cholera entered that city. It was impossible in European cities for cholera to arise *de novo*. If all these undeniable facts were granted, the conclusion was inevitable. Cholera was a contagious zymotic disease, and could only be prevented in the way that typhoid fever, syphilis, or other poison diseases were prevented, *i.e.*, by the segregation of the sick, the disinfection of the discharges from the patient, which should not, if possible, be allowed to enter the sewers, and by the greatest attention being paid to the water-supply. Pure water-supply in Hindoostan had greatly lessened the mortality from cholera among our troops. Then, again, the flooding of the Bristol sewers, by Dr. Davies' advice, in 1866, had cut short the epidemics when they arose in any part of that city. Of course, cleanliness and comfort were admirable prophylactics of all similar diseases, but even the most cleanly people would contract cholera, syphilis, or small-pox, if the contagium were in their midst. Hence, the main point in the prophylaxis of cholera was to take care that it was recognized to be a contagious zymotic disease, and, if this were understood, hygienic measures would be clear enough. As to treatment, it was clear that the purging and vomiting were the efforts made by the system to free itself from an asphyxiating poison. Hence, opium and astringents were contra-indicated, but no clear treatment was as yet made out for the guidance of the profession.

Dr. Corner, of Poplar, was much in favor of disinfection of sewers by perchloride of iron, but did not quite agree that opium was contra indicated. The report of Dr. Lewis, in 1866, with respect to the post-office officials, showed that those men who had used a prescription for incipient diarrhœa containing a confection with opium, showed that opium seemed to have some power in preventing the onset of the disease. The use of doubtful water should be sedulously avoided.

Dr. Ballard said he did not mean to assert that there was nothing living in the causation of cholera, but maintained that it was not proved to be a germ-caused disease. He thought it very unfortunate that the public should be led to think the disease was contagious until this was fully proved to be the case.

Surgeon-general Cornish said the subject of cholera had attracted his attention for the past thirty years. He could not help thinking that it was communicable from persons with the disease to others. The spread of the disease could be greatly lessened by attending to the cleanliness of cities, and to the water-supply. It was probably a germ-caused disease. Dr. MacArthur had treated an epidemic in the east of Fifeshire. There were there two very filthy villages, St. Monans and Pittenweem, quite in the neighborhood of each other. In the first of these no cholera had occurred, but in the second there were many cases. The only difference between these villages lay not in the filth, but in the purity of the water-supply, which in the former came from a mountain lake, while the other was contaminated with sewage. The poison of cholera was clearly very soluble in water. With regard to the opium treatment, he had some doubts what was best to do; he remembered that Murchison had proposed morphia and chloric ether.

Dr. Davies said he would not mind burying the word germ if that was likely to lead to dispute. He had seen a great deal of cholera. First of all, he saw it in Bristol in 1869, when, being a bachelor, he was asked to look after the paupers who were then dying very fast of the disease. He then learned the tactics of the enemy. In the wards he was attached to, none of the boys had been attacked until one boy climbed over a railing and bit off the buttons from the trousers of an old man that had died of the disease. That boy died within twenty-four hours. Dr. Evans, one of the masters of the Bristol school, would insist on drinking water from Jacob's Well, a contaminated source. He died of cholera. Typhoid fever subsequently attacked nine houses supplied with water from that well. In 1866 he acted on the supposition that there was something portable in the poison of cholera, which might be attacked by chemicals. After talking the matter over with Dr. W. Budd, he had the drains flushed with a solution of perchloride of iron, which had acted marvellously well, and was a very cheap method of avoiding death from this terrible disease. As to treatment, he had tried the fractional doses of calomel as advised by Dr. Ayres, of giving two grains of calomel every ten minutes, and also the plan of giving drachm doses, but these had been of no service. All the patients to whom castor-oil had been given died, so that his present views of treatment were almost equivalent to *nil*. Sanitary measures are essential. He agreed with Dr. Drysdale in all he said, but, after all, the non-contagion advocates followed the same practical remedies.

Dr. Pringle, in reply, said cholera did not exist among the lower animals, except, perhaps, among cows. If cholera were infectious or contagious, he thought he would have taken it when treating so many in Hindoostan. The condition of the poorer classes should be seen to, and poor places emptied. Neither opium nor sulphuric ether were of any service.

Dr. Maunsell read a paper on "Summary Views of Medical Aid."

(To be continued.)

"Until the American Medical Association, however, can maintain sufficient order at its meetings to enable it to take a creditable vote upon questions coming before it, it should abstain from interfering further with the arrangements for the International Congress. In fact, for the future it had better leave the matter where it belongs—in the hands of the American medical profession at large, which can be depended upon to provide the necessary intelligence, energy, and organizing ability to make the Congress as successful as any which has preceded it."—*Philadelphia Medical Times.*

THE HOSPITALS MEDICAL SOCIETY OF PARIS.

Stated Meeting, June 26, 1885.

M. VIDAL, PRESIDENT, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

M. FÉRÉOL related the history of a patient whom he had presented at a previous meeting of the Society. It was that of a young woman in whom

PERFORATION OF THE VELUM PALATI

had taken place with great rapidity. The patient denied having had syphilis, and no traces of a previous infection were anywhere discoverable. The general opinion of those present, however, was that the lesion was syphilitic in character. M. Féréol placed the patient upon iodide of potassium for a week, and observing no improvement had then had recourse to a mixed treatment of mercurial inunctions and the internal administration of ninety grains of iodide of potassium. The patient suffered no inconvenience from the treatment, but the infant whom she was nursing had wasted away. The lesion seemed to be constantly increasing.

M. VIDAL thought it would have been better for the infant's sake to depend upon the mercurial alone. He feared that the perforation was due to a subjacent osseous necrosis.

M. FÉRÉOL said that the infant did not suffer as long as the iodide was given alone, but only after the commencement of the mixed treatment. He affirmed that there was no osseous lesion present.

M. FERNET then read a

EULOGY OF M. NOËL GUENEAU DE MUSSY,

whose death occurred recently.

THE PRESIDENT thanked M. Fernet in the name of the Society, and announced that a subscription list would be opened to provide for the purchase of a bronze bust of their late member.

M. MERKLEN then related a case of

TUBERCULAR INOCULATION.

The patient, a woman twenty-six years of age, free from any tuberculous antecedents, either hereditary or personal, had taken care of her husband, who was suffering from phthisis, for a period of six months. She had slept in the same bed with him, and had often to endure fatigue and deprivation of sleep, but had nevertheless remained in good health. Two months after her husband's death she noticed a number of little nodules on the index and middle fingers of the right hand, soon followed by nodosities, first on the anterior aspect of the forearm, and later on the back of the hand and external border of the forearm. There was no pain, but the patient soon began to emaciate, and in a short time the little tumors presented the characteristics of cutaneous tubercular gummata. Examination of the lungs showed signs of tubercular infiltration. Tubercle bacilli were found in the cutaneous lesions. The speaker thought that the case was one of true tubercular inoculation, brought about by the contact of the fingers with the clothes and the sputa of her husband. The pulmonary affection he was led to regard as secondary.

M. VIDAL had seen a somewhat similar case, which, however, differed from this in that the pulmonary disease was primary and the cutaneous tubercles secondary.

On motion the Society then adjourned.

THE INTERNATIONAL DISEASE.—The Neapolitans call syphilis the French disease; the French, the disease of Naples; the Poles call it the German disease; Hollanders and Englishmen refer it to Spain; the Orientals lay it to the Franks, the Persians to the Turks; the Portuguese christen it Castilian, and the Chinese call it the disease of Canton. Other peoples follow the same rule as those mentioned. Syphilis has no father who is willing to stand responsible for its birth.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 10, 1885.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

DR. WALDSTEIN, from the Committee on Microscopy, reported that the specimen presented by Dr. C. H. Knight at the Stated Meeting, May 27, 1885, was epithelioma extending deep into the tissue of the tongue.

EXSECTION OF THE KNEE-JOINT.

DR. JOHN H. RIPLEY presented a patient with the following history: Francisco A——, thirty-eight years of age, native of Italy, laborer, married, was admitted to Charity Hospital, September 14, 1882. His father and mother are both dead; cause of death unknown. The patient has two brothers, both alive and well.

Previous History.—No history, and no evidence of venereal disease. Four years ago, in Italy, the patient had an attack of "rheumatism," at which time he suffered from severe pain in the left knee-joint, which was hot but not swollen. This attack lasted about one year and disappeared spontaneously.

On September 2, 1882, the patient slipped upon a banana-peeling in New York, fell sidewise and injured his left knee, which immediately swelled to "twice its natural size," and became very hot and painful. Twelve days later he entered Charity Hospital, where he was treated for rheumatism for three months, and then transferred to another ward, where extension was employed for two months in conjunction with the use of liniments and exhibition of some internal remedies. Extension was then discontinued for two months, other treatment continued.

Seven plaster-of-Paris splints were then applied, each at intervals of six weeks. Other remedies were then used for a varying length of time, as electricity, tincture of iodine, actual cautery, etc.

On October 21, 1884, exsection of the knee-joint was performed by Dr. J. H. Ripley, and the limb was put up in plaster-of-Paris. During convalescence temperature did not go above 103° F. This occurred only during the second week after the operation, and lasted only a short time. Discharges from the wound were slight in amount and normal in character. At the end of two months the wire sutures joining the sawn ends of the bones were removed, leaving two fistulous tracts of considerable extent on either side of the knee. Under the use of mercuric bichloride solution (1 to 2,000), nitrate of silver, strapping, and other antiseptic and astringent remedies, the sinuses finally healed. No dead bone has been found at any time.

The case was interesting in several respects. In the first place the fact was interesting that the patient had an inflamed knee for nearly three years without giving any evidence of suppuration until the joint was opened. At the time of the exsection Drs. Shrady, Howe, Bryant, and Gibney were present, and neither was willing to commit himself as to the condition of the joint, and several of them doubted the propriety of performing the operation. Dr. Ripley, however, felt convinced that it was useless to continue palliative measures. Even after the patient had been anæsthetized, crepitus could not be detected, and there was no evidence of destruction of the joint; there was simply impairment of motion, and the limb was swollen and tender.

Another point of interest was the illustration the case afforded of the reparative power of diseased bone. Had he removed all the bone diseased there would not have been anything left except the shafts of the long bones above and below the knee. The affected portions were in the condition of osteo-porosity, and filled with abscesses, which Dr. Ripley scraped out, and also removed the bone immediately adjacent.

The patella was extensively carious, and the articular

cartilages were partially destroyed, but at no two opposing points, which explained the absence of crepitus.

The third point of interest was with reference to the use of wires, which, he thought, did but little, if any, good. When he came to remove the metallic sutures (iron), he had almost as much difficulty as he experienced when exsecting the joint.

It was Dr. Ripley's second case of exsection, the first occurring several years ago in the person of a girl in Charity Hospital, whose knee-joint was in substantially the same condition found in this case, and in which he removed about the same amount of bone. The limb, however, was not rendered immobile, and the patient was much longer in recovering than in the present case. The patient presented had two inches shortening. The parts healed by first intention, except where the drainage-tubes were and the wire sutures.

The President regarded the result as a most excellent one, and the case as one affording strong evidence in favor of exsection rather than the more common operation of amputation. He was convinced that the rate of mortality after exsection of the knee-joint was probably one hundred per cent. less than it was ten years ago. He had performed the operation three times during the last winter, and all the patients recovered, and the bone in each instance was so extensively diseased that, had he removed all that was affected, there would not have been sufficient left to justify the exsection. All these limbs were dressed with immovable splints, and wire was not used. He saw no reason why Dr. Ripley should have worked to remove the wire, as it would have done no harm if allowed to remain.

Dr. Van Gieson said that, from what he had observed, although he had never performed the operation, it was better not to use any metallic sutures whatever for holding the bones in apposition. He was unable to see what was gained by their use, as the limb could be placed in the proper position after the operation and kept there by immobile apparatus.

Dr. Ripley thought that if something could be introduced temporarily, to aid in determining when the sawn surfaces of bone were in perfect apposition, it would be all that was necessary.

Dr. A. Jacobi presented a patient with

A CONGENITAL DEFORMITY,

described as follows in a written history furnished by Dr. A. Brothers, House Physician, and Dr. Pope, Senior Assistant, Bellevue Hospital: William McE——, seven years of age, a native of the United States, was admitted

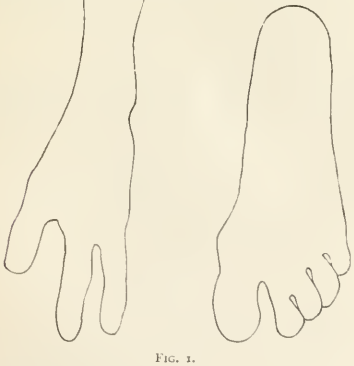

Fig. 1.

June 6, 1885, to the Marquand Pavilion. Otherwise than the deformity the child was healthy. The right upper extremity was normal. The left arm was normal. The left forearm and hand presented the following interesting features: There were only three fingers, the index- and little-finger being absent, together with their corresponding metacarpal bones. The ulna and radius were present, but shorter than the corresponding bones of the other forearm. Left ulna 14 ctm., right ulna 16¾ ctm. The left elbow-joint was imperfectly formed, so that the hand could not be completely supinated. This seemed to be due to the position of the head of the radius. Which of the carpal bones were absent could not be determined with any certainty. The lower extremities presented symmetrical malformations, except

Fig. 2.

in the following respects: The left foot was about one-half inch shorter and smaller than the right. The right thigh was longer than the left. From the right trochanter to the condyle it was 14 ctm. From the left trochanter to the condyle 10 ctm. The movements of the right hip were much easier and freer than those of the left. The patella was absent on the left side, and imperfectly formed on the right. The legs were of unequal length. The left leg, from the condyle to the internal malleolus measured 27 ctm., right leg 28 ctm. On the left foot the second and third toes were slightly webbed. The face and head were symmetrical. The chest showed some rachital development, most marked on the left side The thighs presented forward and slightly outward, as well as downward when the patient stood erect. The patient was an orphan, and had one brother eleven years old, who was also deformed.

Dr. Jacobi also presented another patient, William B——, three years of age, who was admitted to the same pavilion, at Bellevue Hospital, May 19, 1885, with a congential deformity, consisting of

SHORTENING OF THE LIMB, ABSENCE OF THE FIBULA, PRESENT ONLY TWO TOES WITH THREE METATARSAL BONES.

The following history was also written by Drs. Brothers and Pope:

The patient presents a congenital deformity of the right leg and foot. The tibia has an anterior curve at about the junction of the middle with the lower third. At that point there was a longitudinal scar one-half inch in length. There was strong eversion of the foot, and absence of the outer malleolus. There seemed to be no fibula, at least none could be made out. This opinion was confirmed by the position of the foot and the absence of the outer ankle. There were only two toes: the great toe and one other, which latter seemed to be a junction of two toes, as the bones which entered into its formation, except the distal phalanx, were double or separate. There were three metatarsal bones. The great toe articulated with the first of these and the second toe with the other two. The formation of the right lower extremity to the knee seemed to be perfect. It

was impossible to bring the leg into a straight position (line) with the thigh, either from the action of the posterior muscles of the thigh or some abnormality in the formation of the knee-joint. The leg also, when brought as nearly straight as possible, turned out from the median line of the lower extremity, so that the concavity of the entire limb presented externally. The thighs were of equal length. The right leg was shorter than the left by one and one-half inch; right leg, eleven inches; left leg, twelve and one-half inches. The tendo Achillis was present and normally attached. There seemed to be no anterior tibial artery; at least they were unable to find any pulsation where it should be. The posterior tibial was normally present. The right foot was shorter and smaller than the left.

On admission, the child had sore eyes, which condition had passed away under treatment with sulphate of copper and a saturated solution of boracic acid. As to the bones entering into the formation of the tarsus it was impossible to speak with certainty. The os calcis was present, probably also the cuboid and astragalus and the scaphoid. The cuneiform bones seemed to be absent. The tendon (only one could be made out in this case) of the outer group of muscles of the leg could be felt at the outside of the lower end of the tibia seeking its normal attachment. This muscle, together with the absence of the fibula, seemed to cause the eversion of the foot. The right patella seemed to be somewhat smaller than the left, and placed a little external to its normal position. The three metatarsal bones articulated with the scaphoid and cuboid.

Dr. Jacobi remarked that he had seen three or four cases in which one of the bones of the leg was absent. In two of the cases seen previously there was also a superficial scar, as if there had been a perforation of the skin, and it must have been formed within the second month of intra-uterine life, when the forming bone was close to the surface and superficial ulceration took place. When the skin is just forming such an external lesion was very natural.

Dr. Van Santvoord presented a specimen of

ULCERATIVE ENDOCARDITIS IN THE ATHEROMA OF THE AORTA AND LARGER ARTERIES.

J. M——, aged forty-six; single; baker; admitted March 28, 1885.

Family history.—His father died suddenly after an illness of seven weeks at the age of fifty-four. Nature of illness unknown. He had previously been strong and healthy. His mother died suddenly of heart-disease at the age of sixty-three, after having been an invalid for several years. Of four brothers and sisters one he knew to be strong and well, the others he had lost sight of.

Past history.—Patient had been a hard worker; his surroundings had been always good: he was a hard drinker, having been accustomed to go on prolonged sprees ever since his sixteenth year. When a child he had measles, scarlet fever, and small-pox; when twenty-four years old he had a chancre, but no history of secondary disease could be obtained; he had an attack of the rheumatism, commencing in the ankle-joints, during the war; he had suffered from the same disease at intervals since then; for seven or eight months prior to admission to the hospital his feet would be swollen at night after standing all day. Patient's history is imperfect, owing to his apathy and loss of memory.

Physical examination.—Heart: Aortic, direct, and regurgitant and mitral regurgitant murmurs heard. The apex was in the sixth intercostal space, midway between the edge of the sternum and the nipple. Lungs negative. Liver showed diminished dulness. On admission a rose-colored eruption, consisting of small papules, was seen scattered over the body. This eruption gradually disappeared, the spots in some instances becoming almost blue before passing away. Mental condition on admission was good, but he later became apathetic and his memory failed. No abnormality noticed in his urine. On admission the patient was suffering from an acute attack of rheumatism. During the two months of his hospital residence he suffered from irregular recurrences of the malady, which would always yield to a certain extent to ol. gaultheriæ or sodii salicylat. The patient had profuse sweats, which were controlled by atropia. He had irregular exacerbations of temperature, sometimes with and sometimes without exacerbations of his rheumatism. The patient gradually emaciated, became unable to take food, and died of exhaustion, May 31, 1885.

Autopsy.—The body was somewhat emaciated, and considerable post-mortem lividity was noticed. Head: There was a small bony growth which infringed upon the brain between the second and third frontal convolutions, but it had apparently given rise to no symptoms. There was a certain amount of pachymeningitis hæmorrhagica, chiefly over the left hemisphere. The lateral ventricles were dilated, and the ependyma was somewhat thickened. The large vessels at the base of the brain were considerably atheromatous, but those composing the circle of Willis were apparently healthy. Thorax: The lungs were somewhat œdematous, but no infarctions were found. There was a small quantity of clear fluid in each pleural cavity. Abdomen: The liver was somewhat enlarged, fatty, and cirrhotic; the spleen was nearly double the normal size, soft, and was universally adherent; the intestines showed no particular abnormality; the stomach was distended and showed on its mucous surface numerous superficial ecchymoses. The Heart showed the lesions chiefly interesting; the pericardium exhibited a number of irregular thickenings, apparently the remnants of old pericarditis; the ventricles were somewhat dilated, and the muscular substance appeared to be fatty, but no microscopical examination had been made. Two of the leaflets of the aortic valve showed masses of soft vegetations upon the ventricular surface, each surrounding a perforating ulcer, about the size of a crow-quill. The third leaflet was not affected by the ulcerative process, but was somewhat atheromatous upon the inner surface. At the base of one of the columnæ carneæ was a roughened spot about the size of a three-cent piece, and covered with membrane. On the upper surface of one leaflet of the mitral valve a similar mass of exudation was found, but it had no perforating ulcers. Aside from these lesions the heart was normal. The aorta showed advanced atheromatous change, as did also the great vessels and the radial arteries. The pulse, a few days after admission, gave the sphygmographic tracing usually seen, and said to be characteristic of aortic regurgitation with atheromatous arteries. (A sphygmographic tracing was exhibited.)

On looking at the case, it was seen that the only symptoms which pointed toward some morbid process besides acute rheumatism with the valvular lesion ordinarily accompanying it, were the roseola present on admission, the exacerbation of temperature without obvious causation, and the cachexia.

It was interesting to notice that there was a marked systolic murmur at the base and also at the apex. The latter was supposed by some to be evidence of mitral regurgitation. It is a recognized fact, however, that a systolic murmur at the apex is frequently heard when aortic regurgitation is present, and also that it does not mean necessarily mitral regurgitation.

Dr. Ferguson presented a dry specimen illustrating

VOLVULUS OF THE SIGMOID FLEXURE OF THE COLON.

It was taken from the body of a man thirty-seven years of age, married, and a native of Russia.

He complained on several occasions for years of violent abdominal pains and cramps, which passed away and

were similar in character to the trouble for which he had entered the House of Relief on February 27th. The attack for which he sought relief in the hospital had lasted three days previous to his admission. Commencing with a chill, which was followed after a short time by nausea and vomiting, he suffered severe and continuous pain in the abdomen. He was carefully conveyed by ambulance to the hospital, and while his condition was seemingly fair, after arrival he progressively and rapidly failed, and died within four hours after admission.

Autopsy.—Body well nourished; the abdomen was distended and in places presented a greenish hue; peritoneum contained three pints of bloody fluid; the colon was greatly distended; the sigmoid flexure was greatly distended with gas and blood; the wall of the gut in this location was everywhere hemorrhagic; the sigmoid flexure was twisted upon itself once, which prevented the passage of the contents of the large bowel downward; the small intestines were adherent to each other by recent lymph; the intestines throughout were distended and their peritoneal surface intensely hyperæmic; the organs of the thoracic cavity were normal; the organs of the abdominal cavity not referred to were also normal.

Dr. Waldstein said he had wondered that the condition of affairs seen in Dr. Ferguson's specimen did not exist more frequently than it did. He had very frequently found, at autopsy, the sigmoid flexure drawn over into the right side, and a corresponding kink in the descending colon, with immense dilatation of the transverse and ascending colon as far up as the cæcum. He had noticed it with special frequency in elderly persons whose omentum and mesentery were abundantly supplied with fat, and the condition must have existed for some time, as indicated by the enormous distention of the large intestine, perhaps depended upon some local peritoneal irritation or inflammation at the beginning of the volvulus.

PERI-RECTAL DERMOID CYST.

The President presented a tuft of hair removed from a patient twenty-two years of age, who came to him about ten days previous for what was supposed to be a peri-rectal fistula. He had been in perfect health up to eight months ago, when he had what he supposed was a small boil, near the outside of the coccyx, which broke and had remained open. On introducing a probe, Dr. Wyeth found a sinus, but without an opening toward the rectum. He had nearly finished scraping out the abscess with a Volkman spoon, when he noticed a very small opening that admitted a probe to the distance of an inch and a half, when the point of the instrument appeared in the abscess cavity. He then laid this cavity open, which communicated with the abscess proper, and found in the bottom of the furrow a tuft of hairs, the longest of which was two inches in length.

The specimen, so far as the President knew, was unique, and the only explanation which he could offer was that a groove-like inversion of the epiblast took place, and that the tissue designed to produce hair did subsequently develop this growth, and gave rise to a form of dermoid cyst.

Dr. Ferguson said that congenital cysts in the locality of the sacrum were somewhat frequent, and referred to two reported by Dr. Fowler, of Brooklyn, in the *Annals of Surgery*, both of which were lined with cylindrical ciliated epithelium, and the contents of the cysts consisted mainly of these cells, with some cholesterine crystals. They were situated, in Dr. Fowler's cases, higher upon the sacrum than in Dr. Wyeth's case.

Dr. Jacobi said that, from what he knew of dermoid cysts, the large majority of them were found inside rather than outside of the coccyx, between the rectum and coccyx, also between the rectum and the vagina. He remembered to have met with quite a number, and such cases were reported to be quite frequent.

The Society then went into executive session.

Correspondence.

OUR CARDIFF LETTER.

(From our Special Correspondent.)

Cardiff, South Wales, August 2, 1885.

The annual meeting just concluded has been most successful. No unpleasant incident has occurred to mar the proceedings. The weather has been very propitious. At the commencement of the meeting the heat was, it is true, very great, but it has gradually diminished until now the weather is simply delightful. I think the number of members attending is scarcely as great as at last year's meeting at Belfast, but it has not been far short, and the average attendance in the sections has been very good. The proportion of consulting practitioners attending has certainly been larger. I met quite a number of representative men distinguished in their several branches. Among the London consultants present were Dr. Wilks, Dr. Priestley, Dr. Playfair, Dr. Pavy, Dr. Sidney Coupland, Dr. Prosser James, Dr. Bristowe, Dr. Isambard Owen, Dr. Herringham, Dr. Edis, Dr. Gervis, Dr. Grigg, Dr. Hack Tuke, Dr. J. Milner Fothergill, Dr. Drysdale, Dr. J. F. Payne, Dr. Murrell, Dr. Woakes, Dr. Snow, Dr. Dudley Buxton, Professor Marshall, Mr. Erichsen, Mr. Henry Power, Mr. William Adams, Mr. Macnamara, Mr. Edmund Owen, Mr. Treves, Mr. George Field, Mr. Malcolm Morris, Mr. Mansell-Moullin, Mr. Knowsley Thornton, Mr. Keetley, Mr. Bernard Roth, and others. Mr. Reginald Harrison, Dr. Barr, and Dr. Imlach came from Liverpool; Dr. William Roberts and Dr. Walter, from Manchester; Mr. Lawson Tait, from Birmingham; Dr. W. R. Thomas, from Sheffield; Dr. Spender, from Bath; Dr. Reid, from Glasgow; Dr. Berry Hart, Dr. Freeland Balfour, Dr. Byron Bramwell, and Professor Fraser, from Edinburgh; Dr. Jacob, from Dublin; Dr. Cuming, from Belfast, and many others of note from various parts. Several Americans were present, among them were Drs. Duncan, Bulkley, and Stein, of New York, and Dr. Wilson, of Baltimore. The President of the Jamaica branch was present, as were also several medical men from the southern hemisphere. Professor Lesshaft, of St. Petersburg, also attended, and read two papers.

This is not the first visit of the Association to South Wales. In 1853 the annual meeting was held at Swansea. A considerable increase in the number of members has taken place in the thirty-two years which have elapsed between now and then. In 1853 there were only 1,853 members. Now there are 11,249 members. This shows a very great increase, and when we remember that the Association started in 1832 with a muster-roll of only 200 members, its growth is still more marked. There are now thirty-nine branches in Great Britain and Ireland, India, and the Colonies. The invested funds of the Association, exclusive of certain moneys held on trust for special objects, amount to nearly twenty thousand pounds.

Cardiff is a town excellently suited for the purpose of a large meeting, such as that of the Association. It has a population numbering nearly one hundred thousand, and there is ample hotel and apartment accommodation. Private hospitalities, too, abound. There are numerous objects of interest both in Cardiff and the immediate neighborhood. Among these the first place must certainly be awarded to the Bute Docks. As a port, Cardiff ranks third in the kingdom, London being first, and Liverpool second. The Bute Docks are the private property of the Marquis of Bute, who has expended upward of three million pounds upon them, and is still further enlarging them. The docks possess the largest basin in the kingdom. The water from the Severn and Bristol Channel is not admitted to the docks, being so heavily charged with mud, but the docks are kept filled with fresh water from the river Taff, brought to them through a canal which has been constructed for the pur-

pose, and is termed locally "The Feeder." The depth of water in the docks is thus quite unaffected by the tides. At low water the outside of the dock gates is left quite bare by the receding tide, while inside there is thirty-eight feet in depth of (fresh) water. A new dock of forty-seven acres in extent is being constructed. On two mornings running parties of members were taken to see the docks, the railway train being run down an incline to the bottom of the one in construction. The view there was very imposing, the dock walls being fifty feet in height. The "steam navvy" was seen at work, most of the excavating being done by it. We also saw the hydraulic "tip" for coaling ships. Our visit had the advantage of the genial guidance of the chief engineer, Mr. McConnochie, C.E. I am digressing, however, and must return to more strictly medical subjects.

The first day's proceedings went off without any perceptible hitch, though an animated discussion took place over the Council report. One gentleman who got up to speak was interrupted by the President of the Council (Dr. Balthazar Foster), who wished to explain then and there a point raised by the speaker (Mr. George Brown). The latter, however, refused to give way. Dr. Foster, he said, would have the right to reply at the end of the discussion, and if he allowed Dr. Foster to reply then out of his ten minutes, he should have to sit down when the sand-glass had run down, and would have lost part of his time. The report of the Council was finally adopted by an overwhelming majority. The Council has thus been authorized to carry out the scheme proposed by them for purchasing a site in London and building their own premises thereon, instead of continuing to rent as at present. The Association are their own printers and publishers, and have effected a large saving thereby. In addition to building, printing, and publishing offices they have determined to erect a Council chamber, reading-rooms, and rooms for the use of members when in London. It is estimated that to carry out this scheme (which has now been sanctioned by the Association) will cost from twenty to twenty-five thousand pounds. This represents the entire accumulated capital of the Association, or, as one speaker put it, their accumulated savings since the foundation of their society fifty-three years ago. It is hoped to avoid sinking the whole of the large sum mentioned above by renting a site on a long lease, and paying a ground-rent of three or four hundred pounds annually, instead of laying down so many thousands in purchase money. Your readers must remember that twenty thousand pounds means one hundred thousand dollars.

In the evening the *pièce de résistance* was the Address of the President, Dr. W. T. Edwards, of Cardiff. As usual on these occasions, he read it from a copy he held in his hand. Some delay took place before Dr. Edwards commenced reading his address, as on attempting to do so he found he had not sufficient light. After two apologies for the delay a pair of candles was at length obtained. Dr. Edwards said he had no learned leisure to prepare an elaborate address, and he would therefore give a few plain words chiefly of local reference. He gave a very interesting account of Cardiff, its history, antiquities, medical institutions, and sanitation, concluding by making some reference to the immense progress made by the Association since the former meeting in South Wales in 1853. The old saying, "Ubi tres medicos," etc., was certainly not verified on this occasion, as no sign of disapproval was evinced by the allusion Dr. Edwards made (in concluding his address) to the work of Him who came on a divine mission, but who accomplished his purpose largely through ministering to the bodies and healing the diseases of men.

Dr. Edwards sat down amid rounds of hearty applause, which were none the less hearty that the address was brief.

Dr. Strange, of Worcester (President at the Jubilee Meeting in 1882), said Dr. Edwards' address was much shorter than that he had himself delivered at Worcester, but he thought it was also much better. Many people preferred short addresses. Dr. Strange might have added "especially in such hot weather." The heat was indeed intense, much more than could have been expected even in July. Those who travelled here by rail on Monday will long remember the journey. It was almost like being in a Turkish bath with one's clothes on.

During the delivery of the presidential address much merriment was caused by Dr. Edwards stopping and turning round to reprove Dr. Balthazar Foster, who was chattering away in a low tone to his neighbors on the platform. Dr. Edwards looked round once or twice at Dr. Foster, and finding he took no notice, at length deliberately stopped and turning round and putting his hand on his shoulder, said: "I must call our President of the Council to order. He has been a President longer than I have and has got over his nervousness. I have not." When thus publicly rebuked, Dr. Foster at once subsided and Dr. Edwards proceeded amid ringing laughter and applause.

A good deal of merriment was again evoked by Dr. Edwards in returning thanks for the vote of thanks for his address. He frankly confessed that he had looked forward to its delivery with a good deal of trepidation and was glad he had got it over.

(To be continued.)

THE TREATMENT OF MASTITIS BY REST AND COMPRESSION.

To The Editor of The Medical Record.

Sir: The object of this communication is to review certain assertions contained in an article on "The Treatment of Mastitis by Rest and Compression," by Dr. W. F. Milroy, of Omaha, Neb., which appeared in The Record of August 8, 1885. He opens his article in your journal as follows: "While house-surgeon to Maternity Hospital, New York City, a year ago, during the service of Dr. Paul F. Mundé, and through his kindness, I had an opportunity of developing an idea which resulted in the adoption of this mode of treatment in all of our cases in which this calamity threatened." Dr. Milroy introduces in his article the history of a case of mastitis occurring in a woman confined June 17, 1884. Judging from the history given and from a statement elsewhere contained in his article, this was the case in which Dr. Milroy began the treatment of mastitis by rest and compression.

Dr. Milroy makes frequent reference to a paper written by myself, which was based upon eight years' experience in bandaging for breast troubles. This paper was completed in June, 1884, and immediately forwarded to Dr. Paul F. Mundé for publication in *The American Journal of Obstetrics*. A few days later I received a letter from Dr. Mundé, a portion of which I here produce:

"20 West Forty-fifth Street, New York, June 11, 1884.

"Dr. P. A. Harris:

"Dear Doctor—I have looked through your very thorough paper on the 'Treatment of Mastitis, etc.,' and will accept it, if you will consent to wait until October for its publication. I am actually overcrowded and cannot possibly find room for it before. . . .

"Yours truly,

"Paul F. Mundé."

The doctor finally arranged that the paper should be published in the numbers for January and February of the present year.

It will be seen that Dr. Mundé's acceptance of my paper is dated June 11, 1884, and Dr. Milroy first employed his compression and rest under the service of Dr. Mundé, June 23d, of the same year.

The next paragraph in Dr. Milroy's paper to which I would direct attention is the following: "It will be observed that the most essential point of difference between

this treatment and that of Dr. Harris consists in the employment of *firm* pressure instead of the slight pressure which he," Dr. Harris, "recommends."

Regarding the degree of compression required for remedial effect, long experience has convinced me that the best and most grateful results are obtained from moderate compression combined with lifting the gland, this last-named measure being particularly valuable to those patients who are out of bed.

The degree of support which it is possible to obtain from any bandage or appliance that rises but little higher in transverse line than the axillæ, bears no comparison to the lifting effect of any good method of dressing which includes or passes over the shoulders.

Dr. Milroy quotes from my paper an assertion "that the many-tailed bandage, as employed by Dr. Dugas, is objectionable, because it tends to flatten the breast, and press it out of form." Dr. Milroy admits that the many-tailed bandage long since employed by Dr. Dugas is, in its action, so nearly like his own that my objection to Dr. Dugas' treatment might apply with equal force to his (Dr. Milroy's) plan. It certainly does, and I still claim that, everything considered, a change from my method of bandaging which *compresses*, *lifts*, and tends to maintain the *natural form* of the breast, to another which has little or *no* lifting effect, and exerts compression only while pressing the breast out of form, would be a step backward.

Again, Dr. Milroy asserts as follows: "Now, it must be apparent to any who reads the description of the application of Dr. Harris' bandage, that its complexity will deter very many from attempting its use, and many more from succeeding in it. Let him who does not think so make trial of it once."

Dr. Milroy does not squarely say that he has failed in the application of my bandage. We might infer, however, that such is the case. The dressing has, to my knowledge, been applied successfully, not only by surgeons, but by physicians making no claim to the practice of surgery, and I have yet to learn of the failure or inability of any physician to apply the bandage as I have directed. Dr. Milroy drifts still further, and almost insinuates that I am incapable of applying my own bandage, as may be judged by the following quotation from his paper: "When a man of Velpeau's genius meets with so much difficulty," in applying and retaining the bandage, "it is hardly possible that the use of eighteen large safety-pins, as suggested by Dr. Harris, can obviate the whole difficulty."

Let me assure Dr. Milroy that the use of ten or twelve large safety pins does "obviate the whole difficulty," not in my hands alone, but in the experience of many others who will no doubt cheerfully verify my assertions in this relation.

Another objection to my dressing raised by Dr. Milroy is that the patient must assume the sitting posture during its application. This objection is reasonable with physicians who argue that it is especially dangerous for the puerperal woman to sit up in bed before the seventh day. In consequence of the teachings of Drs. Engelmann, Dugas, and others, the practice of the profession has become modified in this particular, and many having abandoned the rule of long recumbent posture, so zealously practised by our fathers, are able to allow their patients to assume the sitting posture for a short time when occasion demands.

Dr. Milroy has scarcely alluded to, much less emphasized, other and very important principles which my treatment involves. I will omit mention of them here, it being my intention to supplement my original paper when the experience of other physicians in the application of the bandage will be added to my own.

I am, sir, yours very truly,

PHILANDER A. HARRIS.

26 CHURCH STREET, PATERSON, N. J.,
August 10, 1885.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 8, 1885, to August 15, 1885.

CAMPBELL, JOHN, Colonel and Surgeon. Granted leave of absence for one month.

IVES, FRANCIS J., First Lieutenant and Assistant Surgeon (recently appointed). Ordered for duty in Department of Platte. S. O. 184, A. G. O., August 13, 1885.

AZPULL, THOMAS F., Captain and Assistant Surgeon. Retired from active service, August 10, 1885. S. O. 181, A. G. O., August 10, 1885.

CHAPIN, A. R., First Lieutenant and Assistant Surgeon. Granted one month's leave, to take effect when services can be spared by commanding general, Department of Missouri, with permission to apply for one month's extension. S. O. 179, A. G. O., August 6, 1885.

WALES, PHILIP G., First Lieutenant and Assistant Surgeon (Fort Cœur d'Alene, Idaho). Ordered for temporary duty at Boise Barracks, Idaho. S. O. 130, Department of Colorado, August 1, 1885.

KENDALL, WILLIAM P. Appointed to be Assistant Surgeon, U. S. Army, with the rank of First Lieutenant, to date from August 12, 1885.

Official List of Changes in the Medical Corps of the U. S. Navy for the week ending August 15, 1885.

BEYER, H. G., Passed Assistant Surgeon. To attend meeting of the American Association for Advancement of Sciences, at Ann Arbor, Mich., and at conclusion of meeting to resume duty at the Smithsonian Institute.

BOYD, JOHN C., Passed Assistant Surgeon. From Navy Yard, Washington, D.C., to special duty at Bureau of Medicine and Surgery, Washington, Navy Department.

LIPPINCOTT, J. C., Passed Assistant Surgeon. To Navy Yard, Washington, D.C., as relief of Passed Assistant Surgeon Boyd.

OWENS, THOMAS, Assistant Surgeon. From special duty at Bureau of Medicine and Surgery, Navy Department, and waiting orders.

SAYRE, J. S., Assistant Surgeon. From U. S. P. S. Independence, to Naval Hospital, Mare Island, Cal.

A NEW METHOD OF ADMINISTERING PEPSIN.—Dr. Prosser James writes in the *British Medical Journal* of May 16, 1885, describing a new form of pepsin. The object which he set before himself was that of preparing pepsin that could be taken in the natural way; that is, a little at a time and not all at once in a large single dose. But patients object often to taking even one dose at meal-time and would be probably with difficulty persuaded to take several at intervals of eating. The wine is ineffectual, as it precipitates the pepsin. A simple mixture of pepsin with salt may be successfully employed as a digestive condiment, provided it be freshly prepared each time; but such a mixture, if kept, is apt to decompose. How to overcome this difficulty was the next problem, but this was solved by bringing the chloride and the pepsin together in such a way as to form a compound, possibly a pepto-chloride. Whether such union occur or not, the compound, Dr. James says, is quite stable. It is a powder having a slight color, but when used as a table-salt is nearly indistinguishable from that condiment. It is called "peptic salt" or "digestive salt," and its use has already given satisfaction in several cases.

Original Articles.

BRONCHITIS—ACUTE AND CHRONIC.

By J. MILNER FOTHERGILL, M.D. Edin., Hon. M.D. Rush Med. Coll., Ill.

Physician to the City of London Hospital for Diseases of the Chest (Victoria Park).

Acute bronchitis is a malady fraught with great danger to life in the very young, the very old, and in those already enfeebled by pre-existing disease. With robust persons in youth and middle age it is comparatively rarely fatal. It is, then, a malady which taxes the bodily powers; if they can be maintained, then all is well, and the disease runs its course safely. Failure of the powers is the matter upon which the physician must keep an unwinking eye. If he loses sight of this cardinal matter the case may easily slip through his fingers.

Bronchitis has its two distinct stages, each requiring its own appropriate treatment. There is, 1, the stage of arrested secretion, and, 2, the stage of excessive secretion.

1. Stage of arrested secretion. Cold is probably the excitant of bronchial inflammation. The poor baby crying in the cold, taking in the chilly air by its mouth, and thus missing the warming plates of the turbinated bones, is usually the victim of bronchitis a few days subsequently. A garrulous old man is talking in a keen wind, and the same result follows. Of course the deed is done before medical aid is sought. In bronchitis distinct rigors are rarely experienced, merely some chilliness, or at most a feeling of some cold water running down the back. The respiration is labored, because the swollen bronchial mucous membrane lessens the bore, calibre, or lumen of the bronchial tubes. Of course, the finer the tubes implicated the more this is felt. When the fine tubes are largely affected, then the attack is termed "capillary bronchitis," and the danger to life is great. Such is the bronchitis set up by a thick London fog, which often slays its hundreds of victims. The expectorated phlegm, when the secretion stage is reached, is not the white froth of ordinary bronchitis, but a grayish mass not unlike an oyster in hue and bulk. Where the larger bronchiæ are chiefly the seat of disease then the malady is comparatively insignificant.

In the first stage of bronchial dryness there is usually much irritation, much useless unavailing cough, for there is, as yet, nothing to be got up. The skin is usually dry. There is rarely marked pyrexia. The first step is to soothe the irritated membrane and to secure secretion. Relaxants are indicated, and of old nitrate of potash, with tartar emetic, would have been the line taken, with some opium and Plummer's pill at bedtime. The indications are to relax the swollen, turgid, dry mucous membrane, and to relieve the cough. The local application of steam, plain or medicated, by means of the "bronchitis kettle," is always good, and can be continued at intervals for hours, indeed until the desired end be attained. Then if there be much complaint of rawness or soreness down the sternum, counter-irritation over the front of the chest is often very useful. As a pupil of the late Professor J. Hughes Bennett, of Edinburgh, of course I did not believe in counter-irritants on starting practice; but my results were so far below those attained by my father, on the old-fashioned plan, that, perforce, I was driven to follow his plan or lose the patients. The best counter-irritant is undoubtedly croton-oil liniment; but it has the drawback of its effects if any other parts of the body, especially where the skin is tender, be accidentally touched by it. Especially is such counter-irritation required by robust countrymen. Then as to the general treatment.

At bedtime a dose of Dover's powder may be indicated, or a grain of opium with James' powder. If a robust man, a few grains of calomel may not be out of place. Whatever may be the objections to the use of opium later on—and they are overwhelming—the sole objection to its employment at this stage is its effect in arresting bronchial secretion. If there be much suffering and irritative cough, the lesser of two evils may be some opiate. Then, if a robust person, the treatment may consist of vin. antim., ℥ xv., vel tinct. aconite, ℥ xv.; sp. mindereri, ℥ j., t.i.d. If a delicate person, pot. iod., gr. iij., sp. mindereri, ℥ j.; t.i.d. (sp. mindereri is liquor ammoniæ acetatis). Hot bottles in bed help to procure free perspiration, by which the general vascular turgescence is relieved, and that of the bronchial mucous membrane as well—the thing desired. In one case encountered in my early days, the young man had repeated attacks of bronchitis, always stubborn in the first stage, for which my father bled him with excellent results; and I had to bleed in another attack after having exhausted my armamentarium of less heroic remedies. When the skin is got to act freely, then the bronchial membrane loses its irritability and secretion sets in, and the case enters upon its second stage.

2. Stage of excessive secretion. With the change in the condition of affairs comes the corresponding change in the treatment. Our object now is not to relieve the discomfort and promote secretion, but to enable the patient to get up the secretion with which the air-tubes are more or less choked, and which, if not got rid of, will accumulate and suffocate the patient. Now comes the struggle between the malady and the patient's power of endurance. No depressants are required now. Opium will arrest the secretion and clog up the bronchiæ. The patient may be wearied with the fight and crave for sleep, begging hard for a narcotic. A narcotic! Why, if it were not for the absolute necessity for voluntary effort to maintain the respiration, the patient would be off to sleep—like Damian in the intervals of the rack—without any need for a narcotic. To give a narcotic is to paralyze those very efforts without which life would soon ebb out. The patient is breathing for dear life, and what we have to do is to help the taxed organism to maintain the struggle. To drag the air through the obstructed air-tubes is trying work. Then cough is required to get up the obstructing mucus. What we now require, *par excellence*, are stimulants to the respiratory centre. The best known of these are ammonia, atropia, strychnia, ipecacuan, and squills. The combination might stand thus:

℞. Ammi. carb. ..... gr. iv.
Tinct. nuc. vom. ..... ℥ x.
Inf. cinchonæ. ..... ℥ j.
4tâ vel 6tâ horâ.

If it be desired to keep up the secretion, then serpentaria might be substituted for the cinchonæ. Senega is in repute, but its taste is most objectionable; it it be used, some spirits of chloroform must be added, by which it is rendered much less offensive. If the case be a bad one,

probably the above combination had best be adhered to. If life is not gravely endangered, then

℞. Liq. atropiæ..... ♏ j.
Liq. am. anisat..... ♏ xv.
Aq..... ʒ j.
M. 6tâ vel 4tâ horâ,

may be preferable. If the case be mild, then

℞. Ac. hydrobrom..... ʒ ss.
Sp. myristicæ..... ♏ ij.
Syr. scillæ..... ʒ ss.
Sp. chloroform..... ♏ xv.
Aq..... ʒ j.
M. Three or four times daily.

may be sufficient; and a very elegant and palatable cough mixture this forms.

Bronchitis runs a definite course; and here, as in fevers, to tide the patient over the limited time is to save him. Failure of the powers under the demand upon them is the danger to be steadily kept in view. These powers must be sustained by meat-broths containing baked flour (*i.e.*, starch largely converted into soluble dextrine) and milk, with malt extracts or malted preparations; in fact, food containing grape-sugar—the natural food of the body. Alcohol may be indispensable, and must be given with no niggard hand if need be. Support! Supporting measures of all kinds in unstinted quantities are indicated. But there is one part of the organism that specially needs support, and that is the right ventricle. The strain on the right heart is at times tremendous, and failure of the right ventricle is the common cause of death. The right ventricle of a dugong, or other diving mammal, would be a grand acquisition in a bad case of bronchitis. If there be a pre-existing mitral lesion, then the state of the right heart is a cause of the gravest anxiety.

On commencing practice a number of cases of bronchitis went the wrong way, despite my utmost efforts. Chagrined and complaining of this one day to an old practitioner, and saying that in each case there was a mitral lesion, he consoled me thus: "You will find such cases will all die!" This was comfort of a kind; but the remark induced me after that to take the condition of the right heart into my calculations; and after that my results were more satisfactory. Digitalis was added to the mixture; and then my old friend's forecast was falsified! A hot bottle, or hot bran-bag, or hot poultice over the front of the chest is not only comfortable, but it keeps up the action of the heart, as well as loosens the phlegm.

Acute bronchitis may occur primarily and leave a chronic condition behind it, or it may occur as an intercurrent condition in a case of chronic bronchitis. When acute bronchitis is a primary malady it usually leaves behind a certain amount of vesicular emphysema, which in young subjects usually disappears; but occasionally one comes across a case of chronic bronchitis with well-marked emphysema in a girl barely in her teens. For aiding the recovery of the lung-elasticity strychnia seems to me the best drug. As to the resultant chronic bronchial condition, it may require iron in atonic cases. In gouty cases solvents of uric acid, potash, and lithia are indicated. Balsamic remedies are useful in all chronic catarrhal conditions of mucous surfaces, from urethritis to a bronchial flux.

Chronic bronchitis.—This condition usually dates from some acute attack in the past, sometimes in the by-past. It may be a rheum without any true inflammatory first stage. As such it is an outcome of mitral disease, often masking the cardiac condition. Rarely, if ever, is it found without more or less emphysema. Every acute exacerbation leaves a worse condition of emphysema behind it. In the young the lung largely recovers, but not so in older subjects. Pursy or broken-winded before a new acute attack, the chronic bronchitic comes out of the struggle worse broken-winded than before. The efforts of coughing have further strained or ruptured lung tissue no longer possessed of the elasticity of early years. Consequently it is of great importance to avoid all acute bronchial trouble as far as possible.

This condition of emphysema is one of great clinical interest. Ordinarily it is assumed that emphysematous persons are barrel-chested. This is a very crude view. Of course, all are most familiar with the barrel-chested, red-faced, blue-lipped, puffing persons obviously emphysematous. At each inspiration the sterno-mastoid muscles are seen to stand out like plough-cords. Often the skin between them can be seen to be sucked in simultaneously—deep fossæ being formed. The act of inspiration is a laborious one. Except when bustled by effort, the respiratory act is not increased in number per minute. The acceleration produced by effort will often tell more accurately than physical examination of the chest of the actual extent of the emphysema. If the patient be in bed, the respiration is seen to be distinctly abdominal. The comparatively immovable thoracic case is lifted up bodily by the neck muscles while the diaphragm descends. The lungs are too full of air even upon complete expiration. If called upon to speak, the patient will rest his elbow upon the nearest object, so as to fix the shoulder, and then take a breath. If sitting, both hands will be seen resting on the thighs so as to fix the shoulders, and thus get the benefit of the accessory muscles of respiration. On physical examination cardiac dulness is more or less completely lost from the attenuated lung spreading over the heart. The liver dulness does not commence till the ribs are nearly reached, and then the liver, pushed downward, is found extending considerably beyond the border of the ribs. The diaphragm of the emphysematous person is flattened; it is dragged down by the violent inspiratory efforts, while the voluminous lungs obstruct its return. The viscera on the abdominal side of the diaphragm are pushed down bodily. The thoracic space is thus increased. But if the abdomen be distended with flatus, then the descent of the diaphragm is impeded, and a condition of "asthma" is set up. Indeed, "wind" is the plague of their lives with emphysematous persons, with or without bronchitis.

All chronic bronchitic persons are more or less emphysematous, and therefore what has just been said applies to them. In addition, they have often some thickening of the bronchial lining membrane, which adds to their dyspnœa. Sometimes they have genuine attacks of spasmodic asthma.

The lines upon which such cases are to be treated are as follows: The respiration is embarrassed, and, therefore, a stimulant to the respiratory centre is indicated. So strychnia comes first. Then it is well to keep the bronchial secretion free and unchecked, and for this end ipecacuan suggests itself. But ipecacuan is a tonic to the liver as well, and so is doubly useful when there is nervous congestion. Some might add some benzoic acid. The right heart is embarrassed, so some digitalis will be useful. Then as to carminatives for the "wind." The essential oils, the peppers, and the nauseous gums are all good for flatulence. In pill form, a good combination is as follows:

℞. Strychniæ..... gr. $\frac{1}{4}$.
Pulv. ipecacuan..... gr. $\frac{3}{8}$.
Pulv. digitalis..... gr. $\frac{1}{2}$.
Pil. galban. co..... gr. ij.
Bis aut ter in die.

If the bowels are not regular, a small quantity of podophyllin or croton oil may be added. To some readers such a compound may seem ridiculous. A derisive smile may flit over the features, betraying what is passing through the mind. But all the same this pill has done wonders for a large number of persons whom I know and have prescribed for.

And now as to rest at night, a very important matter. It may be well to try a mixture, so:

℞. Bromidi ammoni..... ℈ j.
Tinct. camphoræ..... ℥ j.
M.

A favorite night pill with my late father, who had an extensive experience of bronchitis in all forms, was:

℞. Morphiæ mur..... gr. ¼
Benzoic acid..... gr. j.
Pil. scillæ co..... gr. ij.
M.

Here the benzoic acid counteracted the effect of the morphia upon the bronchial mucous membrane, and prevented arrest of the secretion. And such a pill really does give a great deal of comfort to old bronchitics whose rest at night is broken by bouts of coughing. Paregoric or tinct. camph. co. is a compound built upon this plan, and is often of great service where opium or morphia alone are baneful remedies.

Usually on leaving the recumbent posture on waking a coughing bout commences. Phlegm has gathered during the night on parts which have become more or less accustomed to it. But with movement the phlegm is dislodged, and then cough is set up for its removal. The accumulation of the night is thus got up after much exertion, and then the chest is comparatively clear of phlegm, and comfortable. Sometimes the morning cough is trying, and shakes the sufferer terribly. Some hot tea or other hot fluid affords relief; while it is well to teach the patient how to cough properly. There may be no education possible or required in the matter of sneezing, but certainly this is not the case with coughing. The patient must be taught to fill the chest with air before giving way to the expiratory action—cough. Watch a person who has never learned to cough. See the futile attempts. The shallow inspiration, the useless, impotent cough. At last a paroxysm of cough comes on, the chest become fully inflated, and then the cough which follows expels the offending phlegm, a sense of relief following its ejection. When we reflect upon the sacculated condition of the bronchial tubes, and remember the firm wall of hardened-lung tissue of these bronchiectases, we can see how full inflation of the lung is essential for such compression as alone can force out the contents of such sac. To first fill the chest with air is the one condition of successful cough. To learn to do this is to save much useless coughing, and much strain upon the lung-tissue, leading to further emphysema. So much for learning to cough.

When the phlegm is hard to get up, from some check to the bronchial secretion, the inhalations of steam are good, and iodine, Friar's balsam, eucalyptus, and other agents may be added to the steam. Some persons burn benzoin pastilles.

For attacks of "asthma" the different "fuming" remedies advocated in the article on "Asthma" (MEDICAL RECORD, August 8, p. 141) are indicated.

There are some points about the clothes and hygiene of chronic bronchitics worthy of mention. They are a chilly race, from impaired oxygenation and defective heat production. They are scant of breath and cannot get about. They must be warmly clad; yet they cannot bear any weight of clothes. Consequently their clothing must be light as well as warm. Furs in the daytime out-of doors; down bed-quilts for the night. Warm under-clothing in the day; and a flannel night-gown. On cold nights a fire in the bedroom is good. A respirator is invaluable for preventing fresh attacks of cold. Fifteen years' experience of a respirator has told me its value and entitles me to speak. Never mind its unsightliness; or the remarks it may provoke on the part of the thoughtless, or even the sympathy of others. Like the gloves, it should always accompany hat and stick. If it had not been for a respirator the writer would have been a pursy, broken-down bronchitic, instead of a well and fairly preserved man approaching middle age.

Then, again, remember the position of the liver. Pushed out of its warm nook, thrust down so that much of it is only covered by the thin abdominal parietes, it is liable to chills. Consequently a cummerbund, or broad belt of several thicknesses of flannel, is most desirable. This protects both the liver and the kidneys. Specially is this last matter of moment where there is a gouty element in the case—a very common complication. The food should not be too highly albuminous; and the patient ought to be encouraged to take fat as far as possible in any and every form.

By such measures the chronic bronchitic may live on for years—practically on sufferance, *i.e.*, by taking proper care, death being the result of neglect or forgetfulness.

OPERATIONS FOR SALPINGITIS.[1]

By W. GILL WYLIE, M.D.,

NEW YORK.

I HAVE eleven specimens of diseased uterine appendages, removed since I presented fourteen in January last. What I have to say is but supplementary to my recent paper upon this subject, read before the New York Academy of Medicine. Of the eleven, all but one recovered. The one that died was a case of pyo-salpinx. The left tube was distended with about two ounces of dirty grumous pus. I succeeded in elevating it without its bursting, although it was firmly fixed by extensive adhesions. Great care was taken to prevent the escape of any of the pus into the peritoneal cavity, but I learned afterward that the same sponges in which the pus was caught were used again during the operation. Of the twenty-five cases, nine were private cases, and all recovered; sixteen were hospital cases, and three were lost.

These cases were all carefully treated before resorting to the operation. Pledgets of cotton saturated with a solution of boro-glyceride, alum, and glycerine were inserted in the vagina twice a week to improve the local circulation and soften out indurated tissues. After the uterus became movable to more or less extent, those suffering with menorrhagia were curetted, while in those suffering with dysmenorrhœa the os was dilated and the lining membrane treated; in most cases the dysmenorrhœa was relieved. I have about reached the conclusion that when the lining membrane of the uterus is neither diseased nor congested dysmenorrhœa is very rare, that the congestion preceding the menses may cause pain, and often is associated with local peritonitis, but that the flow certainly, in many cases, gives relief to the pain caused by diseased tubes and ovaries.

The cases were selected for operation not because they were favorable or likely to be easy. In every instance the patients were bedridden invalids or were totally unfitted to do ordinary work and keep out of the hospital or the poorhouse. With the exception of three or four all had extensive adhesions, and only one of the twenty-five had no adhesions. The majority were well-marked cases of pyo-salpinx, several were complicated by pelvic abscesses and hectic fever. I have never yet opened a patient and failed to find and lift up and remove the appendages on account of adhesions. So far I never had hemorrhage take place after the operation. The three cases lost were hospital patients, and on account of the extensive adhesions the abdominal cavity was exposed. All died from septic poison on the fifth or sixth day. The death-rate of twelve per cent. is not high, even when compared with the European operators, for if I had eliminated those with pelvic abscess, etc., and put them in different tables, a different showing could be made. In Bellevue we labor under many disadvantages; our means of isolation are imperfect, and our assistants are changed every six months, and it is easy to

[1] Presented to the New York Pathological Society at its meeting, June 24, 1885.

have a record spoiled by one poor assistant. Comparing this with other laparotomies that I have done, the death-rate is just the same. Of twenty-five laparotomies of different kinds of tumors, three died, but one of these was hysterectomy for cancer, and another hysterectomy for the removal of a fifty-pound fibroid, and both were done in Bellevue Hospital.

Leaving out all hysterectomies, and I have had only one death in twenty-one laparotomies, other than those for removal of the tubes. In twenty-four laparotomies, done in private practice, I have lost only one, and that was my first ovariotomy, where I attempted to enucleate a large cyst that was strongly adherent all over its surface. Since then I have in all such cases removed only a part of the sac, and sewed the remainder to the abdominal incision and drained the remaining pouch.

Case XV.—I. M——, a native of the United States, aged twenty-eight; married, has had seven children and four miscarriages; admitted October 1, 1884. She gives a history of almost constant and profuse leucorrhœa of a month's duration or longer. Complains of slight pain in back. States that about three weeks ago she experienced an attack of faintness. Since then she has been very constipated, and has had heavy dragging sensations about the rectum. Physical examination shows a large fluctuating tumor, the size of a large cocoanut, situated behind, below, and to left of uterus, which is large, subinvoluted, and pushed to left and forward. Pelvic hæmatocele was diagnosed, and this was confirmed by the withdrawal of a little brownish, broken-down blood with a small aspirator. Treatment: complete rest in bed, laxatives, tepid douches (1 to 10,000). November 8th, discharged improved.

On January 15, 1885, patient readmitted. Since discharge has had a severe attack of pelvic peritonitis and discharge of bloody matter per rectum. Comes to hospital complaining of severe pain in the left side. On examination small tumors on both sides; left very sensitive. Treatment: laxatives, douches, rest in bed, pancreatized milk.

January 19th.—Operation. Many adhesions found on both sides, completely embedding both tubes and ovaries, and attached to right ovary was what seemed to be sac of an old hæmatocele. The lumen of tubes were occluded by adhesions, and the ovaries degenerated, breaking into shreds in removal. Patient made a rapid recovery. Highest temperature was 100⅘°. Discharged February 23, 1885, cured.

Case XVI.—T. D——, native of Ireland, aged thirty-five; single, no children, no miscarriages; admitted November 2, 1884. Menstruation is regular, but is accompanied with pain; complains of bearing-down sensations when she stands, and of a soreness and of pain in left iliac region. Patient is hysterical. Examination shows uterus to be anteflexed and drawn to left side; there are signs of pelvic peritonitis; ovaries are enlarged and prolapsed. She was put on usual treatment of laxatives, douches, tampons, peptonized milk. No improvement, patient bedridden.

February 2d.—Operated on. There were numerous adhesions; tubes embedded in adhesions; ovaries enlarged and cystic, especially the right. Highest temperature, 101⅘°. Patient recovered entirely from the operation. She had a cough, due to phthisis.

Case XVII.—E. P——, a native of England, aged twenty-nine; a widow; has had three children and three miscarriages; admitted December 13, 1884. Menstruation has been profuse and attended with severe pain; leucorrhœa constant; complains of severe cutting pain in right iliac region, extending down the thigh; also of "bearing-down" pains; bowels habitually constipated; micturition painful. Examination showed signs of extensive pelvic peritonitis, uterus fixed in position, and tumor in right broad ligament, the left also thickened. Ordered rest, tampons, douches, on alternate days laxatives, pancreatized milk. General condition improved and uterus more movable.

February 28, 1885.—Tait's operation. There was some hemorrhage on account of adhesions having to be torn; the omentum and intestines adherent; right ovary large and congested, and tube seat of catarrhal inflammation, and one-half inch in diameter; left ovary cystic and enlarged. Patient soon recovered. Highest temperature, 101⅘. Kept under observation several weeks, local pain perfectly relieved and general health much improved.

Case XVIII.—M. C——, a native of Sweden, aged fifty; single; admitted February 18, 1885. Has had no children and no miscarriages, was treated for two years for vaginitis, supposed to be specific, and she gradually became so much of an invalid that she could not work. Patient still menstruates; with menstruation has had but little trouble; but now is unwell every second or third week. There is a constant yellowish discharge from uterus, and in considerable amount. For several years patient has suffered from pain in right iliac region and in back. The pain is described as "smarting," and is at times severe, keeping her much of the time in bed. Is troubled with constipation and painful micturition.

Physical examination: Both ovaries sensitive, and left prolapsed and plainly felt. Uterus enlarged and somewhat prolapsed. Patient was given complete rest in bed, douches and laxatives, and pancreatized milk a few days before operation.

Tait's operation on April 2, 1885. There were few adhesions. Three small fibroids in uterine wall posteriorly. Tubes enlarged, left ovary prolapsed. Patient made a good recovery. Highest temperature, 101°.

Case XIX.—D. S——, born in Germany; aged twenty-seven; married; admitted February 7, 1885. Has had two children and no miscarriages. Suffers from menorrhagia and severe pain in back, and in both iliac regions, though it is worse in left. Is habitually constipated. Hysteria well marked. Physical examination shows adhesions from pelvic peritonitis. After tampons, douches, and laxatives, curetting was done on February 23d. There was some improvement, less hemorrhage, but severe pains continued, especially in left side. Now that induration and thickening of peritoneum had disappeared, a tumor could be made out on left side.

April 6, 1885. Operated on. Adhesions of the left side were strong and extensive, completely covering the tube and ovary. Both ovaries cystic, the left enlarged. Both tubes were in a state of catarrhal inflammation and imperforate. Patient recovered without any trouble.

Case XX.—E. F——, a native of Ireland, aged twenty-three; single; admitted April 11, 1885. No children, no miscarriages. Menstruates every two weeks and loses much blood. Has severe pain before and during the flow. Leucorrhœa not constant. Suffers from darting pains in hypogastrium and in back. Examination reveals a tumor in left broad ligament. Usual treatment was carried out.

May 7, 1885, she was operated on. Strong adhesions on left side, the left ovary enlarged, and tube tensely dilated with pus to one-half its diameter. The right ovary and tube were diseased to less extent, but abscess involved ovary and end of tube, and were removed. After tube was lifted up, sponges were placed to prevent escape of contents of the tubes into cavity of peritoneum. Thick dirty pus squirted out in a stream with first cut of scissors.

Died May 11, 1885, on fifth day, from septic poisoning and gradual extension of local into general peritonitis. As no pus escaped into cavity, and the stump was carefully cauterized, it was probably the use of some of the same sponges with which the pus had been caught that infected the peritoneum. Drainage-tubes were used and washing out tried in vain. Coil of cold water, etc., were also resorted to.

Case XXI.—M. H——, a native of the United States, aged forty; married; no children, no miscarriages. Menstruation always regular. No leucorrhœa. Patient was

perfectly well until middle of last February. Since that time has suffered from pains in back, hypogastrium, in left iliac region, and in left thigh. This pain in the thigh was often severe, and resembled sciatica. Examination shows uterus to be enlarged, lifted upward, forward, and a little to the left, and fixed above pubic bone by a tumor as large as a baby's head, which seemed to be held down in pelvis by left broad ligament. When the tumor was first noticed, in February last, she says it felt about as large as an orange. Patient was kept under observation for two months. The tumor increased in size, and by end of this time felt like a thin cyst, and by one leading gynecologist was diagnosed as a simple cyst of broad ligament, and he recommended that it be opened per vaginam, etc. The fixation of the uterus and tumor, however, and the uncertainty of operations per vaginam on pelvic tumors, caused me to prefer laparotomy. After the usual preparatory treatment this operation was done, May 9, 1885. The left broad ligament was found very much thickened and spread over a fibro-cystic tumor of the left ovary. The left Fallopian tube was fully as large as the thumb, and six inches in length. A pint of yellowish fluid was drawn from the tumor by means of a trocar and cannula. It was found impossible to uproot the tumor from under the ligaments so as to secure a pedicle. About three-fourths of all the sac was removed, after the broad ligament had been tied next to the uterus, and as far to the left as posssible, thus allowing the intermediate parts, including about five inches of left Fallopian tube, to be cut away. The borders of the remnant of the sac were ligated and sewed into the abdominal wound, and a drainage-tube was put into the peritoneum above the tumor, and one into remnant of sac. Portions of the wall of the cyst, which at the bottom contained a flaky, gelatinous mass, were nearly an inch thick. The patient did well. In twelve days the ligatures came away, and in five weeks she was up and about.

Case XXII.—J. F——, a native of the United States, aged twenty-five; single; no children, no miscarriages. Menstruation has always been too frequent, and during the last four years has often occurred every two weeks, and has been attended with severe pain. There has been a yellowish discharge from the uterus, considerable in amount, and almost constant. She has suffered from pain in back and in iliac regions, especially the right, and since the age of eighteen these pains have been severe. She has also been troubled with constipation, headache, nausea, and vomiting. Nine months ago was treated for endometritis. This was followed by two or more attacks of pelvic peritonitis, which were supposed to be pelvic diseases. For past eight months has been bedridden, and has been in the habit of taking opium several times a day.

Physical examination shows both ovaries prolapsed and sensitive, the right enlarged. There are also unmistakable signs of adhesions, due to pelvic peritonitis.

May 17, 1885.—Operation after preparatory treatment. Both tubes were found catarrhal and enlarged, and covered with bands of adhesions. Fimbriæ of both tubes adherent and lumen obliterated. Although pulse was constantly over 105 and very weak previous to operation, she made an uninterrupted recovery. Five weeks after operation was sitting up in bed, and had taken no opium for ten days.

Case XXIII.—E. McC——, a native of Ireland, aged twenty-one; single, no children, no miscarriages. Has physical signs of first stage of phthisis. Admitted March 17, 1885. Menstruation regular until three years ago. Intervals have been prolonged to six weeks, but lately intervals have been too short and she has lost much blood. Always has great pain when unwell. Abundant leucorrhœal discharge of yellowish color. Patient is unable to work on account of pain, often severe, in iliac regions and in back. Is constipated. Micturition painful.

March 26th.—Cervix uteri dilated, which gave some relief from pain at menstrual periods. Physical examination shows signs of pelvic peritonitis and a small tumor on left side.

May 29, 1885.—Operation. There were few adhesions. Left ovary cystic. Right ovary not much diseased. Tubes seat of catarrhal inflammation. Patient made a rapid recovery.

Case XXIV.—J. R——, a German by birth, aged twenty-nine; married, no children, four miscarriages; admitted May 26, 1885. Menstruation is regular, but she loses a considerable amount of blood, and has severe pains during the flow. Some leucorrhœal discharge, white in character. For two years has suffered from sharp, burning pain in both iliac regions; also from headache and pain in back. Not very much constipated. Micturition accompanied with burning pain.

Physical examination: There was evidence of pelvic peritonitis, uterus fixed by old adhesions, and a tumor could be felt in the left broad ligament. It seemed about as large as a lemon, and was in a mass of adhesions. The right broad ligament was also thickened.

June 4, 1885, abdomen was opened by the usual incision; the omentum was adherent over the uterus and broad ligament. It was removed, and some adhesions of the intestines were separated, and the enlarged and adherent tube and broad ligament was unrolled from the cystic ovary on the left side. A cyst of the left ovary as large as a lemon was removed with the tube without breaking. The right tube and ovary were found also diseased and removed, the lumen of both tubes were occluded by adhesion of the fimbriated extremities.

Patient made a good recovery.

Case XXV.—A. M——, born in United States, aged twenty-six; married, one child, one miscarriage; admitted June 13, 1885. Menstruation always too frequent; duration about one week, always attended with severe pain. For a year has had a yellow and stringy leucorrhœal discharge. Complains of severe pains in sides and in back. Habitually constipated, and suffers from headache. More or less bedridden.

Physical examination: Uterus fixed to some extent by old adhesions due to pelvic peritonitis. Both broad ligaments thickened. After usual treatment she was operated on June 17, 1885. When the adherent omentum was removed the left tube was found curled backward toward the uterus, with its fimbriæ firmly adherent to the anterior wall of the uterus, and it was found necessary to tear off the adhesion as it was so firm. Both tubes were covered with adhesions and their fimbriated extremities closed. These were removed with both ovaries, which were abnormally cystic. Now, June 25th, patient is doing well; no bad symptoms have showed themselves.

Summary.

No. of case.	Date of operation.	Age.	Condition.	Children.	Miscarriages.	Disease.	Result.
XV.	Jan. 19, 1885.	28	Married	7	4	Catarrhal s. and degenerated ovaries.	Recovered.
XVI.	Feb. 2, 1885.	35	Single	0	0	Catarrhal s. and cystic ovaries.	do.
XVII.	Feb. 28, 1885.	29	Widow	3	3	Pyo-salpinx.	do.
XVIII.	April 2, 1885.	50	Single	0	0	Catarrhal s. and atrophied ovaries.	do.
XIX.	April 6, 1885.	27	Married	2	0	Catarrhal s. and cystic ovaries.	do.
XX.	May 1, 1885.	23	Single	0	0	Pyo-salpinx ovaritis: abscess.	Died.
XXI.	May 9, 1885.	40	Married	0	0	Hypertrophied tube. Fibro-cystic ovary.	Recovered.
XXII.	May 17, 1885.	25	Single	0	0	Catarrhal s. Fimbriæ adherent.	do.
XXIII.	May 29, 1885.	21	Single	0	0	Catarrhal s. Left ovary cystic.	do.
XXIV.	June 4, 1885.	29	Married	0	4	Catarrhal s. Fimbriæ adherent. Small ovarian cyst.	do.
XXV.	June 17, 1885.	26	Married	1	1	Catarrhal s. and occluded tubes.	

According to Dr. Gordon the circulation of the blood was familiar to the Chinese physicians two thousand years ago.

FRACTURE OF THE CLAVICLE, FOLLOWED BY VICIOUS UNION—GRADUAL INFRACTION OF CALLUS—REMOVAL OF DEFORMITY.

By WILLIAM STONE TORREY, M.D.,

SCRANTON, PA.

The case cited below presents no peculiar features, but the treatment is apparently novel and the result certainly exceptional.

Miss A——, aged thirteen, consulted me on February 23d, with reference to a deformity of the shoulder, the result of an injury which she had sustained a month previously.

History.—On January 23d, while playing upon the ice, the patient fell, striking upon the left elbow. When the fall occurred, the forearm was flexed upon the arm, the limb extended laterally from the side, and the elbow directed behind the lateral median line of the body.

A surgeon was consulted at the time, and a diagnosis of fracture of the clavicle was made. No treatment was instituted.

On February 23d, the time at which the child was brought to me, one month after the reception of the injury, the case presented the following characteristics:

Inspection revealed a marked deformity on the affected side. The scapula and prominence of shoulder were displaced downward, forward, and inward

The distance from sternum to acromion was apparently less on the affected side than on the sound side. When the patient assumed the erect posture, the shoulders being thrown back, the distance between the spinous processes of the vertebræ and the posterior border of the scapulæ was proportionately greater on the affected side than on the sound side.

Mensuration showed the distance from sterno-clavicular to the acromio-clavicular articulation on the affected side to be four and four-fifths inches. The distance between the same points on the sound side was five and a half inches.

Palpation over the bone showed the tumor to be a large amount of "provisional callus" which had been thrown out aronnd the seat of fracture.

From the shape of the callus a diagnosis was made of oblique fracture of the middle third of the clavicle in a direction inward and backward, followed by vicious union. A small degree of reduction could be accomplished by placing a pad in the axilla, adducting the arm, and at the same time making counter-pressure upon the shoulder in a backward direction. An unfavorable prognosis was given, but as the friends were very anxious to have something done, I consented to institute some treatment with the object of lessening the deformity.

Treatment.—On February 28th a shellac board-splint was cut, extending from the tip of one shoulder, posteriorly, to the tip of the opposite shoulder. This was moistened and moulded to fit the bony prominences of the scapulæ and vertebræ. The splint was well padded and secured with an ordinary roller bandage (the axillary spaces being first protected by padding) by figure-of-eight turns crossing behind. On top of this plaster bandages were applied, commencing under the axilla, passing over the shoulder, under the axilla again, over the shoulder, and then across the back. When the second turn over the shoulder was made, considerable force was exerted in order to draw the shoulder backward, and the force was then retained by passing the roller across the back and securing by passing under the axilla and over the shoulder on the sound side. When the bandaging was completed and the plaster had set, the result was a firm plaster cast extending from shoulder to shoulder posteriorly, with firm plaster rings surrounding the shoulder anteriorly and inferiorly. Behind, the inferior margin of the splint was nearly on a line with the posterior-inferior angles of the scapulæ. The ring passing around the shoulder on the affected side was purposely made broader than that on the sound side, in order to obtain a fulcrum through which to make extension outward. The arm was not confined to the side, but was allowed to hang.

More complete extension backward than that already resulting from the figure-of-eight turns above described was effected by means of padding introduced between the splint and the posterior aspect of the shoulder. The least resistance being in a backward direction, the broad portion of the splint was carried away from the posterior aspect of the shoulder, and in consequence of this a counter-force was exerted on the acromio-clavicular articulation by that portion of the plaster-of-Paris ring which was anterior to it. The outer fragment was thus carried backward.

This padding was increased every few days, and padding was also introduced between the plaster-of-Paris ring inferiorly and the axilla, in order to enlarge the size of the fulcrum and thus increase the outward extension force.

The splint was removed on April 3d. Examination showed the tumor to have decreased in size. The distance on the affected side from the sterno-clavicular to the acromio-clavicular articulation was five and one-half inches, the same as on the sound side.

When the patient stood erect, the shoulders being thrown backward, the appearance of the spaces between the posterior border of the scapulæ and the spinous processes of the vertebræ were alike on both sides.

July 17th.—Examined the patient again upon this date. A large amount of the "provisional callus" has been absorbed, and the contour of the two sides, both anteriorly and posteriorly, are nearly alike.

Clinical Department

A CASE OF COMPOUND FRACTURE OF THE RIGHT HUMERUS COMPLICATED BY DISLOCATION OF THE ELBOW-JOINT AND BY INJURY OF THE BASILIC VEIN AND MEDIAN NERVE.

Dr. E. C. Carter, Assistant Surgeon, United States Army, sends us the following: On the night of November 10, 1883, I was called to see W. C——, a lad, fifteen years of age, who had been thrown from his horse. The boy was lying in a wagon. He was pale and seemed to be in great pain. On examination I found he was suffering from a compound fracture of the right humerus about two inches from its lower articular surface. The patient had fallen from his horse while at full gallop, and the posterior surface of his arm, midway between the elbow-joint and the *line* of fracture, had struck a pointed stump. The lower fragment of the bone was dislocated forward, producing a marked protuberance in front of the elbow-joint. The lower end of the upper fragment was thrust through the skin so as to project an inch or more.

The end of this fragment was obliquely serrated, and in its passage through the soft tissues of the arm had lacerated the basilic vein and injured the median nerve. As was to be expected, the patient had lost much blood. The hemorrhage was controlled by pressure and the patient immediately etherized. Care was taken to place the light—the hour rendering a light necessary—in such a position that the wind blew from it toward the patient. As the wind was steady and strong there was little danger of the ether vapor becoming ignited. The blood and dirt in the vicinity of the wound were carefully removed, and an antiseptic wash of carbolized water was liberally used. The dislocation was easily reduced, but some difficulty was experienced in getting the broken bone into its proper position, though this was finally done without removing the extremity of the projecting fragment, as at one time appeared necessary.

Antiseptic dressings were applied, and the arm was

placed in a favorable position, as anchylosis was expected. Those in charge of the patient insisted on taking him next morning to his home, a distance of sixteen miles. During the journey, in a wagon without springs and over rough roads, the dressings became displaced, and in washing the wound, the patient's friends used *pure* carbolic acid, which produced severe and painful burns. The patient was brought back to me after the lapse of four days, and his condition was such that it was necessary to have him under close professional supervision. The wound was inflamed and full of stinking pus. The patient's temperature, taken in the axilla, was from 101 to 102° F.; his pulse-rate was 100 a minute. His tongue was foul; he had no appetite and had lost flesh. His complexion was pasty, the odor of his breath was unpleasant, and he complained of headache and weakness. All dressings were removed and the wound was again thoroughly washed out with carbolized water, and movable antiseptic dressings were applied. Citrate of iron and quinia in doses of six grains was administered three times a day, and an aperient and a generous diet were prescribed. At the end of twenty-four hours the wound looked healthy and the pus had no bad odor. The temperature and pulse rate were normal, and at no time afterward did the temperature rise above 99° F. The case required careful attention for five weeks. At the end of that time the bone was firmly united, the superficial wound healed and the elbow-joint partially anchylosed. An anterior and a posterior splint were firmly and evenly bound along the whole length of the arm, so as to relieve the strain on the humerus, and the fore-arm forcibly extended and flexed. In one month from the time artificial extension and flexion were begun the patient could extend and flex the arm with ease. Pronation was more slowly acquired, and for some time there was anæsthesia of the palmar aspect of the index- and middle-fingers and inner half of the ring-finger. The thenar group of muscles was partially paralyzed and atrophied. I attributed this anæsthesia and paralysis to the injury of the median nerve sustained at the time of fracture.

Six months after the wound had healed I saw the boy herding cattle, and as he was guiding his horse with one hand, and whipping it with brutal ease with the other, it was apparent that he had recovered all the normal uses of his arm and fore-arm.

Progress of Medical Science.

A Case of Scrotal Gastrocele.—Dr. M. Schmidt was consulted by a patient who had for some time suffered from digestive disturbances, accompanied at times by vomiting of a black, flocculent, sour, but not fecal, smelling fluid. There was no constipation. There was a scrotal hernia, which gave a loud tympanitic note on percussion, and presented fluctuation at its lower part. A diagnosis was made of hæmatemesis, probably from ulcer or cancer, though it was thought possible that the hernia might contain a part of the stomach. The patient's condition would not permit of an operation, and he died shortly afterward. The autopsy showed that the hernial sack contained the middle two-quarters of the greatly dilated stomach. There was neither carcinoma nor ulceration of the gastric walls.—*Deutsche Medicinal-Zeitung*, June 4, 1885.

The Influence of Cimicifuga Racemosa upon Parturition.—At a recent meeting of the Chicago Gynecological Society, Dr. J. Snydam Knox read a paper in which, from his clinical observations, he drew the following conclusions: 1. Cimicifuga has a positive sedative effect upon the parturient woman, quieting reflex irritability; nausea, pruitus, and insomnia, so common in the last six weeks of pregnancy, are always rendered less distressing, and often disappear under its administration. 2. Cimicifuga has a positive antispasmodic effect upon the parturient woman. The neuralgic cramps and irregular pains of the first stage of labor are ameliorated, and often altogether abolished. In fact, during the first indiscriminative use of the drug in all cases, I had the mortification, with a few women, of terminating the labor so precipitately, and without prodromic symptoms, as to be unable to reach the bedside before the birth. 3. Cimicifuga relaxes uterine muscular fibre, and the soft parts of the parturient canal, by controlling muscular irritability, thus facilitating labor, and diminishing risks of laceration. 4. Cimicifuga increases the energy and rhythm of the pains in the second stage of labor. 5. It is my belief that cimicifuga, like ergot, maintains a better contraction of the uterus after delivery. It is my habit, however, to administer from fifteen to thirty minims of the fluid extract of ergot after the birth of the fœtal head, and I have had but few opportunities of testing this effect of the cohosh. My method of administration has been to give fifteen minims of the fluid extract of cimicifuga in compound syrup of sarsaparilla each night for four weeks before the expected confinement. One fluid ounce of the fluid extract of cimicifuga to three fluid ounces of compound syrup of sarsaparilla—dose, one teaspoonful—makes just the required quantity.

Malaria and Pregnancy.—Dr. G. C. Nijhoff, of Amsterdam, discusses, in the *Weekblad*, the question of the relation of malaria to pregnancy, adducing some observations of his own. Some years ago it seemed to be the general opinion that pregnant women were very rarely affected by malarial fevers. Thus, Griesinger (Virchow's *Handb. der spec. Path. und Ther. Infections-Krankh.*, 1856) found that, during the prevalance of a quartan fever in Prague, only two out of 8,639 pregnant and parturient women were affected. Again, Credé states (*Monatsch. für Geburtsh.*, Band xv. S. 1, 1860) that, in Leipsic, during the three years 1856–59. there was scarcely a case of tertian ague in a pregnant woman. Mendel and Ritter have also recorded the comparative immunity of pregnancy from malarial attacks, for which the latter accounts by the smaller degree of exposure to malarial influences during pregnancy. When, however, it does occur, it does not, according to both Mendel and Ritter's observations, exercise any remarkable effect on the course of the pregnancy. On the other hand. Göth, of Klausenburg. found (*Zeitsch. für Geb. und Gyn.*, Band vi. S. 17, 1881) that, during a severe epidemic of a malarial nature, 46 out of 881 pregnant women were attacked; and of these 46, in 19 the labor was premature, and in some the children were still-born, and, even when they were alive, the size and weight were abnormally low. Bompani also (*Centralbl. für Gyn.*, 1884, S. 821) is of opinion that malaria causes more premature labors than syphilis.

The discordant views of authorities, of which the above may be taken as examples, extend also to the treatment which should be adopted in the malaria of pregnancy, some, as Cazeaux, advising that quinine should be given as the surest preventive against abortion; while Petitjean (Charpentier, *Traité des Acc.*, Tome i., p. 562. 1883) and Monteverdi consider that quinine is a powerful ecbolic; the latter thinks it even more active than ergot. The writer mentions particulars of four cases, in which malaria attacked pregnant women, quinine being given. In one of these the labor came on five weeks before the calculated time; but the child was of full length. and it was uncertain whether it was really premature. In another case the labor occurred at about the right time, but immediately after a severe attack of fever, the weight of the child being 2.8 kilogrammes (about 6 lbs. 2¼ ounces). The other two pregnancies terminated normally, with healthy children. With respect to the mutual effect of malaria and the process of labor, Ritter was of opinion that labor tends to arrest a malarial attack, suggesting, as an explanation of this, that the hemorrhage may perhaps account for it. Göth considered that labor is prolonged by malaria to double its normal

length, and stated that artificial assistance by forceps or extraction of the placenta was requisite more often than in cases uncomplicated in this way. The writer's own observations induce him to agree with Ritter rather than with Góth. In one of his four cases, the malarial attack did not return for twelve days after the labor; and in two more cases the patients were free for fourteen days after labor. In all these cases, the labors were normal, with very little hemorrhage. It is, of course, often difficult to diagnose malaria in the puerperal state. Ritter believed that puerperal women are peculiarly susceptible to malaria, but that they are less exposed to its influence than other people. He, however, mentioned fourteen cases, of which only three had had attacks during the pregnancy. He also thought quinine less satisfactory in its results than usual, owing to the enfeebled digestive power. The author's experience of puerperal malaria is very limited.—*British Medical Journal*, July 18, 1885.

Foreign Bodies in the Digestive Canal.—The case is related by Dr. Kohn of a melancholic patient with suicidal tendencies, who, in the hope of ending her life, swallowed three large spoons, each seven inches long, and with a bowl about an inch and a half wide. They were all passed from the rectum lying together, the convexity of one bowl fitting into the concavity of the other, and surrounded by a mass of consistent fecal matters. The passage of these bodies had excited a mild peritonitis at first, and later an attack of diarrhœa, but these disturbances speedily subsided, and no trouble was experienced after the spoons had been passed from the bowel. This case is almost unique, considering the large size of the spoons and the comparatively sharp edges of their bowls.—*Deutsche Medicinal-Zeitung*, June 4, 1885.

Is Acetonæmia the Cause of Diabetic Coma?—Contrary to the observations of Patters in 1857, whose views have been accepted by subsequent authorities, Albertoni, writing in the *Rivista di Chimica, Medica, e Farmaceutica*, endeavors to show that acetone is not the poison which causes death in diabetic patients. Indeed, when administered by the mouth it is, if pure, less poisonous, he states, than ordinary ethylic alcohol. The phenomena observed in diabetic coma are by no means always similar to those produced by acetone. He gave large doses (one hundred grammes) of glucose to rabbits, but could detect no acetone in the urine. Isopropylic acid is partly changed in the organism, acetone being formed; part of the acid is, however, passed unchanged. In man, when a dose of six cubic centimetres is given by the mouth, it is detected unchanged in the urine. Aceto-acetic ether does not produce symptoms of diabetic coma, but it does cause albuminuria and hæmoglobinuria, and is certainly eliminated in an unaltered condition. From previous researches it seems evident that aceto-acetic acid often exists in diabetic urine, its presence being detected by the red color given with perchloride of iron if the urine is not boiled or treated with an acid. This acid is well borne by the organism, and cannot be the cause of severe poisoning. The condition which governs its appearance in the urine is the reaction of the urine and that of the renal parenchyma. If the urine is acid, the aceto-acetic acid is decomposed, forming acetone; but if alkaline, neutral, or slightly acid, the aceto-acetic acid is found unchanged. This is the explanation of the discordant observations on this subject. It is probable that the formation of aceto-acetic acid explains the presence of albumen, which is sometimes observed in diabetes. Crotonic acid, the formation of which in diabetes was demonstrated by Stadelmann, cannot be considered as poisonous, two grammes producing no effect on rabbits. Crotonic aldehyde is, on the other hand, highly poisonous, even in small doses, four drops producing in a rabbit dyspnœa, and even narcosis, with the exhalation of an odor resembling crotonic aldehyde, and other phenomena which are described by Kussmaul as present in diabetic coma. Large doses caused powerful disturbance and rapid death, with epileptiform convulsions.—*Lancet.*

Maggots in External Auditory Meatus. — Dr. Vogt reports the case of a youth, aged seventeen, who came to his office June 20, 1885, and gave the following history. While plowing corn on June 17th, a "blow-fly" entered the meatus auditorius externus of the left ear, and as he was a considerable distance from home and it caused him no great inconvenience, he allowed it to remain there for over an hour before he went home and had it extracted. The next day, he thought he felt something moving in his ear, and used a warm milk injection which gave relief for a short time. The next day he used a turpentine and milk injection, but as this did not produce the desired effect and his ear became inflamed and caused him a great deal of pain, he came to me for relief. Upon examination I found the parts swollen and inflamed, and no less than a dozen full-grown maggots in the meatus and on and around the tympanum. I removed the maggots with an ear-scoop, washed the ear with a five per cent. solution of carbolized warm water, and afterward poured a small quantity of carbolized olive oil into the ear, which had the desired effect of giving permanent relief.—*Western Medical Reporter*, August, 1885.

Acute Pericarditis in the Aged.—The diagnosis of acute pericarditis is sometimes difficult even in adults, but it is yet more so in the aged. In them there are often old pulmonary lesions, chronic bronchitis and emphysema, or valvular and other cardiac affections which serve to mask the sounds proper to pericarditis. If, in addition to these, there are also signs of recent intrathoracic disease, the symptoms become still more obscure. This is shown by M. Chas. Lejard, in a recent thesis (*Revue Médicale*, June 6, 1885), who states that of the thirty-two cases of pericarditis in the aged, which form the basis of his paper, in but nine was the diagnosis made during life. The symptoms which should excite suspicion in the mind of the medical attendant are, the author says, a certain difficulty in respiration, usually increasing for several days, an elevation of temperature from 2° to 3.5°, dull, irregular, intermittent, or even tumultuous heart action, and a corresponding state of the pulse. If, during the course of a pneumonia or some other febrile disease, a sudden fall of temperature occurs, and is accompanied by the irregularity of heart-action above referred to, one ought to think of the possibility of pericarditis. The examination of the physical signs and the presence of friction-sounds would serve to establish the diagnosis, but this will be usually a diagnosis by exclusion. The treatment of pericarditis in the aged offers nothing of note. Local counter-irritant blisters or dry cups are to be used, but, above all, tonics are indicated, such as quinine, alcohol, and digitalis. These will form the basis of the treatment. If there is a very abundant serous effusion, the pericardium may be tapped, and the fluid drawn off, the advanced age of the patient affording no contra-indication to this mode of treatment.

Perforation of the Intestine caused by a Bimanual Examination.—Dr. Schwarz relates the case of a woman, forty-six years of age, who had suffered for a long time from a fibrous tumor of the womb. Shortly after a bimanual examination the patient was seized with peritonitis, and died. The writer supposed that the inflammation was caused by a rupture of the uterus and the passage into the abdominal cavity of some mercuric chloride contained in a vaginal douche. At the autopsy, however, he found that there had been adhesions of a loop of intestine to the uterus, and these adhesions had been broken and the gut ruptured by the manipulations, notwithstanding the fact that the examination had been conducted with great gentleness owing to the tenderness of the womb.—*Journal de Médecine de Paris*, June 7, 1885.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, August 29, 1885.

MEASURES RECOMMENDED BY THE ROYAL ITALIAN SOCIETY OF HYGIENE FOR THE PREVENTION OF CHOLERA.

IN a recent number of the *Gazetta degli Ospitali* are to be found the conclusions arrived at by the Italian Royal Society of Hygiene, as to the best means of preventing the spread of cholera. As these conclusions are based on the wide experience obtained from the prevalence of the dread scourge in Italy last year, they deserve attention. While offering little that has not already been recognized in connection with this subject, the whole is admirably epitomized, and for this reason, as well as the above, it is well worth consideration.

The Society announces :

I. The fundamental basis of public prophylaxis against cholera is a well-ordered, independent sanitary administration, composed of medical persons especially instructed in the subject, supported by the Government. To this end is recommended :

1. A reorganization of the existing service in the best possible manner.

2. That schools and laboratories be established to educate physicians in hygiene, that they be able to fill these high and responsible offices properly.

II. Relative to the etiology of cholera, Professor G. Sormani gave the Society the following facts, deduced from observations made during the epidemic of 1884 :

1. That infected garments are the means in many instances of propagating cholera-germs, and that they are more to be feared than people themselves.

2. That the clothing of the feet should be the objects of special attention, as these, coming in constant contact with the surface of the soil, are more easily contaminated in infected places, and maintaining constantly a certain degree of moisture, can preserve, transport, and diffuse with great facility the cholera-germs.

3. Linen washed in infected water transmits the cholera.

4. That probably in linen and garments infected with cholera, and in contaminated water, the cholera-germ acquires a special character (sporification ?) whereby it has greater tenacity and duration.

5. That animals and birds, especillay those which are filthy, seem to be able to carry the cholera-germ in their furs and feathers.

6. That surface-water and surface-soil have been proved to be a means of transmission of the cholera-germs.

7. That running water transports from the surface of the soil the germs, which multiply and diffuse themselves.

Therefore, he concludes that the local authorities should be empowered to take measures to prevent the contamination of the water-courses, for when this happens it will not be possible to check the spread of the disease ; and that to provide efficacious safeguards against cholera the Government should favor with money and encouragement the study undertaken in Italy for a more exact knowledge of the facts which go to establish a basis of scientific prophylaxis.

III. The Society considered the means of preventing the invasion of cholera. These should consist of :

1. Strict quarantine on the frontiers adjacent to the infected countries.

2. Sanitary inspection of the quarantined. Disinfection of garments with moist heat at 100° C. Destruction of the same if polluted with infection.

3. That while free passage of new merchandise destined for commerce be permitted, all free passage of every kind of effects, garments, and objects used should be forbidden.

4. Whenever return of travellers is possible it should be done. Emigrants (operatives, peasants, and poor people) coming from infected districts should be returned under the care of the Government, and preferably by water rather than by land.

IV. The Society recommend that the quarantine laws relative to quarantine of harbors and pest-houses be revised to correspond more with the altered conditions of travel. That the land and sea quarantine be proportioned to each other.

V. Relative to internal quarantine it is suggested that a sanitary cordon under the direction of the Minister of the Interior be instituted ; that the circulation of people from infected districts be prevented ; and that those who come should be quarantined and disinfected. The fumigation of people and of effects ordinarily performed, at the railway stations or elsewhere, ought to be prohibited as useless and also dangerous.

VI. For local prophylaxis the Society advise :

1. To combat as far as possible the first case of cholera or suspected case. That such be taken to a suitable hospital ; that suitable fumigation follow, and every precaution be used that the infection do not spread.

2. To institute common ovens for practising effectual disinfection. To take great care to separate infected clothing from that going to the general laundry, and to banish useless fumigation of people and things.

3. To hinder everything tending to increase the misery and panic of the people ; to favor the establishment of a public kitchen and inspection of all alimentary substances and of drinking-water.

4. Recommending, above all, the care of the hygiene of the house, of the soil, and of the subsoil of inhabited places.

VII. Lastly, the Society maintains that in the quarantine of persons from infected districts ten days afford ample opportunity for disinfection.

THE INTERNATIONAL MEDICAL CONGRESS.

THE *Journal of the American Medical Association*, which has so steadily maintained a character for dignity and dulness, has recently lost its first attribute at least, without perhaps undergoing much change as regards the second. Its endeavors to prop up the present managers of the International Congress have led it into a curious position. It is no longer the organ of the profession, or even of the Association, but is rather a strident defender of the clique who are bent on having their own way. Despite the almost universal condemnation of the policy developed at New Orleans and Chicago, the *Journal* continues to defend it. In doing so, it has not had the courage of other journals, which it accuses of being "organs," but has systematically repressed all adverse critical comments even from disinterested European brethren. It has sneered at the eminent gentlemen who have withdrawn from the Association, and has characterized them as thoughtless and foolish malcontents. Although resignations have now been going on steadily for over two months, it still chooses to regard the action as "hasty."

With all this, however, we are each week informed, that if the withdrawing members will hurry up and return to the fold, it may not yet be too late for them to be forgiven! The *Journal* is in much the position of a man on a raft, who threatens the passengers of a staunch ship with all the dangers of the sea if they do not soon come down and help him navigate.

Last of all, the *Journal*, to help itself along, has been guilty of misstatements, which, however, we can easily believe were accidental or typographical. We quoted last week from it the announcement that Dr. John H. Packard had withdrawn his resignation. We have the authority of the *Medical News* that this is not true.

Our Chicago contemporary, in discussing the question, has in every instance evaded the real issue, viz., that there should be no politics in a scientific convention. The introduction of this issue it cannot excuse, and wisely has not attempted it.

From its last announcement, we infer that no serious attempt at compromise is to be made. The present managers will, it is true, change the rules so that any regular physician can be a member of the Congress. But it is simply an insult to intelligence and self-respect to assume, as is done, that this is any concession. Gentlemen of New Code affiliations can contribute in money and work, but cannot share the honors!

There is a demand from the whole American profession, from that of England, Germany, and the other countries of Europe, that the Code issue be entirely left out. Will not the committee, which is to meet in this city on September 3d, respond to this demand? It would not be very difficult, and the success of the Congress would then be assured.

INDIAN SPRUE.

NATIVES of temperate regions resident in tropical countries are subject to a variety of diseases, affecting chiefly the chylopoëtic system, which are known to us only from text-books, or as they are occasionally seen in the persons of those who have contracted them during a sojourn in hot climates. Among the most interesting of these disorders, and one of which we have seldom seen a satisfactory description, is that known as Indian sprue, or aphthæ tropicæ. One of the best accounts of this disease which has yet appeared, and one upon which we have drawn largely in the following description, was published some years ago by Dr. C. L. Van der Burg,[1] and translated for the Reports of the Imperial Maritime Customs of China, No. 2, 1884.

Indian sprue is an endemic disease occurring in the East and West Indies and other hot countries. The affection is chronic, non-contagious, never existing as an epidemic in the true sense of the word, although there may be a large number of sufferers in a single locality, and does not occur as a sequela of any other disease, but is protopathic and *sui generis*. It is not commonly fatal, but its course is slow and exceedingly protracted, and even after recovery there exists a marked tendency to relapses if the patient does not return to a temperate climate. The cause of the disease has never been conclusively determined, but it would appear to reside in suppression of the action of the skin and expulsion of the blood from the superficial capillaries, leading to a condition of abdominal plethora and modification of bile secretion. Women are more commonly attacked than men.

Indian sprue may, for convenience of description, be divided into three stages, though it does not always run the entire course, and the different periods are very variable as regards their duration. The first stage is that of gastro-intestinal catarrh. There is at first an indefinable feeling of malaise, which is soon followed by symptoms of digestive disturbance. There is a feeling of epigastric fulness, without distinct pain, which is increased after eating, but it is at the same time almost impossible to refrain from taking food in quantity, owing to the ravenous appetite which the patients experience. There is abdominal distention from the accumulation of gas, relief from which is often obtained by explosive eructations, in which not only gas is expelled, but also a sour, acrid fluid. Vomiting is an occasional symptom, and is usually periodic, occurring about noon. The tongue at this time may be clean or slightly furred, but soon little red specks appear along the edges and at the tip, which are seen on close examination to be injected papillæ. The action of the bowels now becomes irregular, there being perhaps a natural stool one day, and the following day, or may be even after a few hours, a watery, light-yellow passage may occur. The patients do not present a cachectic appearance, though there is usually a yellow tinge to the conjunctivæ. There is no fever.

In the second stage, all the symptoms of gastro-intestinal disturbance become more pronounced. Abdominal distention is greater, vomiting is more common, pain in the stomach is complained of, and there are frequent intestinal discharges of pultaceous, clay-colored matters. The liver is diminished in size to such an extent that even during full inspiration its lower border can with difficulty be felt behind the ribs. The appearance of the tongue at this time is characteristic. The red specks increase in number and size, covering finally the entire organ, while the surface becomes dry, glossy, and smooth,

[1] Indische Spruw (Aphthæ Tropicæ). Batavia: Ernst & Co. 1880.

seeming to be wholly denuded of its epithelium, and is very sensitive. The redness is very marked, and Dr. Van der Burg regards its depth of color as a sure indication of the progress of the disease. The mucous membrane lining the mouth and pharynx is colored in a similar way. The under surface of the tongue presents a like appearance, but has a somewhat bluish tinge. The urinary secretion is diminished in quantity, and is albuminous, but no casts are present. The skin is dry. There is great muscular weakness and profound mental depression, approaching almost to melancholia. It is not very often that the disease passes beyond this stage, and when it does so it is usually because of persistent disregard of dietetic rules. Recovery frequently occurs. The third stage is one of general wasting; vomiting is very frequent and follows immediately upon the ingestion of food, the diarrhœa becomes watery, the patient becomes feverish, and death occurs from exhaustion. The mucous membrane covering the tongue and other parts of the mouth becomes fiery red, the gums retract, and large clefts and fissures appear on the tongue.

Such are, in brief, the symptoms of this distressing disease, but they are not always so marked or so regular in their appearance, and variations from the typical description are the rule rather than the exception. The pathognomonic sign, however, is the appearance of red specks, not vesicles, upon the tongue coincidently with the symptoms of gastro-intestinal catarrh.

The treatment of Indian sprue is mainly dietetic, although the value of certain drugs is not to be denied. The food should be chiefly farinaceous in character, consisting of rice, corn-meal, arrow-root, and the like. Various kinds of prepared foods for infants and invalids, of which so many have been put on the market of late years, here find a field of eminent utility. Most succulent vegetables, cabbage, onions, peas, and similar articles, are to be avoided. Beef is injurious, but most of the varieties of white meats, poultry, veal, and pork, are well borne. A mode of treatment of comparatively recent origin, known as the "fruit cure," is one that promises to find favor with patients and physicians alike, as it has, in many cases, been productive of excellent results. Patients subjected to this "cure" live almost exclusively on fruits of various kinds, chiefly those grown in temperate climates, such as peaches, pears, apricots, and apples. Necessarily canned fruits must be depended upon in great measure, and a preference is expressed for those of American canning, the European preparations containing too much sugar. Along with these, strange to say, cucumbers and other articles containing a large proportion of water are given. It is sometimes difficult to induce patients to undertake this method of treatment, which is so opposed to their ideas of a diet suitable in diarrhœa, but the results which have been obtained from it are said to have been most gratifying. Among the drugs most in favor are the mineral acids, nitrate of silver, and mucilaginous preparations. Opium and calomel are injurious.

It is not often that we meet with this strange disease in temperate climates, yet it is occasionally seen in the persons of those who have returned after a long residence in the tropics, and as descriptions of it are so few, so inaccessible to the majority of physicians, and usually, also, so imperfect, and ever misleading, the account here given may prove to be of assistance to some perplexed practitioner in whose way chance has thrown a sufferer from Indian sprue.

"WHAT TO DO IN CASES OF POISONING."[1]

BEFORE us is a diminutive volume bearing this title. The knowledge of its contents might prove more valuable to its possessor than that of many a quarto.

What graduate is there who does not feel, after he leaves college, hanging over him like the sword of Damocles suspended by a hair, the dread possibility of a summons to a case of poisoning? His mind is full of scraps of information with which he has passed his examinations and obtained his degree. Made more prominent because of the questions asked with reference to the subject, toxicology and antidotes have assumed an awe-inspiring importance. The dread of cases of poisoning ever remains with him; but some way the knowledge which carried him to the triumph of obtaining his degree oozes away with time, leaving only a vague notion of just when and why the plaster from walls and ceilings should be scraped to administer to the poisoned victim; when the gallons of coffee should be given; when the patient should be flagellated and walked about, and when on no account he should be raised from a recumbent position; when the whites of eggs should be called for; when the vinegar cruet should play an important part as furnisher of an antidote—all this exceedingly useful and necessary knowledge becomes, in many a medical mind, perfectly clear on every-day topics, a hopeless jumble.

Says the writer of the little volume: "I can imagine nothing more painful than to be called to a case of poisoning, and not to know what to do." Many a doctor has a sneaking notion of how painful this would be, and yet he remains unprepared for such an emergency; putting off refreshing his rusty knowledge, allowing himself to go unsupplied with the most common antidotes; procrastinating like a man who knows he ought to make his will, but does not.

The doctor cannot, like a cook, have his recipe-book in his hand; he must carry it all in his head. His ideas must be ready, like fire-engines, for full service when called upon.

To avoid the complexity of the subject and the perplexity of diagnosis, a search has been made for that philosopher's stone, a "multiple antidote;" that is, a preparation which will neutralize the toxic action of all or most all the active poisons. Two such are given as very nearly answering the purpose.

One of these is the iodide of starch, which is efficacious in poisoning by sulphuretted hydrogen, the alkalies, the alkaline sulphides, and especially the alkaloids, with which iodine forms an insoluble compound. The other is given as follows: Saturated solution of sulphate of iron, 100 parts; water, 800 parts; calcined magnesia, 88 parts; purified animal charcoal, 40 parts.

The iron solution should be kept separately, and the magnesia and charcoal mixed in a bottle, and the whole well shaken together. It may be administered *ad libitum*, a wineglass or more at a time. It is said to

[1] By William Murrell, M.D., F.R.P.C. Fourth Edition. Published by H. K Lewis. London: 1884.

render preparations of zinc, arsenic, and digitalis absolutely inert, and to partly neutralize the action of mercury, morphia, and strychnine. It has, however, no action on the alkaloids, and none on phosphorus, antimony, or hydrocyanic acid.

Better by far than "the multiple antidote" is "the antidote-bag." We commend it to our readers. If you would purchase immunity from the dread of encountering a case of poisoning, possess "the antidote-bag;" then, if the summons comes at midnight, or any other hour, you will go forth without trepidation. You will have in hand everything you need—antidotes, emetics, stimulants, hypodermic syringe; not to mention the little book, your fountain of wisdom.

"Every doctor should have a stomach-pump," also says our mentor, or at least be sure that he knows how to rig up an apparatus which will do the same work.

For a young physician there links an added terror to the summons to a case of poisoning, the dread of having to encounter the legal proceedings which will surely follow a fatal issue. Our little book gives sage advice in such an event, and adds this, which is sufficient to bolster up the courage of any faltering medical witness: "If you have read up on the subject, you should be more than a match for any barrister."

You have your book of reference at hand, your "antidote-bag" or "multiple antidote," a stomach-pump; you have become primed to give legal evidence, as if accustomed to it all your life. One thing still remains. "Every medical man should get up the subject of *ptomaines*," remarks our author with emphasis. These closely resemble vegetable alkaloids; but they are cadaveric substances, generated during the decay of the dead body, and are supposed to be alkaloids. It must be known that they exist, and how they react.

It should ever be remembered that, as Dr. Murrell tersely and correctly puts it, "all rational treatment of cases of poisoning is founded on a correct appreciation of the physiological action of drugs." It is the same with reference to diagnosis. "There is no royal road," he says; "the only way to arrive at a correct conclusion is to utilize your knowledge of the physiological action of drugs." Then you will always know "what to do in cases of poisoning."

JACCOUD'S METHODS OF TREATING PHTHISIS.

Every modern writer upon phthisis seems to feel it a duty to lay stress upon the possibility, and even frequency, of cure or arrest of phthisis. There is a great deal of hopeful prognosis also floating through medical periodicals and monographs. Yet we are still unable to find any author who is willing to give in exact terms the percentage of cures which he has had.

The writer is willing to admit that among some five hundred cases which have come under his observation, he can record only one positive and one relative cure in the first stage, and two relative cures or arrests in the second stage. Still we are being constantly assured that phthisis is curable in all stages, and, perhaps, it is quite as well that such a hopeful feeling should be the prevalent one.

One of the most emphatic supporters of the doctrine of the curability of phthisis is Professor Jaccoud, whose work[1] has just been translated by Dr. Montague Lubbock.

Professor Jaccoud is a unicist, believing all forms of phthisis to be tubercular. Clinically, however, he makes the usual distinctions of pneumonic or caseous phthisis, chronic miliary phthisis, or the ordinary form, and acute miliary tuberculosis. Leaving out the last-named type, the forms of phthisis which are most curable are, first, the pneumonic, and next the chronic miliary phthisis. The different types of chronic phthisis may be arranged, as regards possibility of cure, as follows: First of all, arthritic phthisis, or phthisis in rheumatic persons; next, the primary, then the scrofulous, the innate, the hereditary, and finally the diabetic form, which is always incurable.

M. Jaccoud announces a certain novelty in his conclusions and views on treatment. We turn, therefore, with special interest to this latter subject, which he, aside from his chapters on prophylaxis, divides into four heads: the hygienic, medicinal, climatic, and the treatment with baths and mineral waters. But little stress is laid upon anything but the climatic and medicinal treatment, these including, of course, ordinary hygienic measures.

M. Jaccoud has studied personally and with care the subject of climates. He makes but two classes of climates, and his views are simple, clear, and, so far as they go, correct. Climates are either high and cold, or low with a steady and mild temperature. High climates have a positive therapeutic effect, low climates are simply negative in value in that they only enable the system to be put in good general condition.

The subject of the medicinal, hygienic, and dietetic treatment is naturally most interesting, since, after all, in the vast majority of cases the victims of phthisis must depend upon these.

In the initial period of phthisis, Jaccoud recommends as a general course of treatment milk or kumyss twice daily, cod-liver oil or glycerine, and arsenical granules. Three ounces of oil daily is the least amount that will do any good, according to Jaccoud. This is certainly an important statement, since all over the United States cod-liver oil is given in doses of only two to four drachms. Arsenic should be given in the form of granules of gr. $\frac{1}{64}$. Of these two are taken daily, and the number increased up to eight or ten. Glycerine may be substituted for oil, in doses of three to four tablespoonfuls daily. A drop of essence of mint and two drachms of rum or brandy may be added to it.

So much for general medicinal treatment; but our author attaches very great importance also to local indications. Counter-irritation over the affected part is always necessary, and the specially important thing is that it be kept up continuously. Jaccoud prefers to use Vienna paste. When cough is accompanied with habitual expectoration, pure creasote, in small doses, with the oil or glycerine, is recommended, and is believed to act upon the catarrhal as well as the pulmonary lesions.

Pyrexia is perhaps the most important single symptom

---

[1] The Treatment and Curability of Pulmonary Phthisis, by S. Jaccoud, Professor of Medical Pathology in the University of Paris. Translated and edited by Montague Lubbock, M.D. (London and Paris), M.R.C.P. (Eng.). Pp. 407. New York: D. Appleton & Co. 1885.

to be opposed. According to Jaccoud this pyrexia is, generally speaking, either inflammatory or septic in origin. The symptomatic or inflammatory fever is usually best treated with quinine, about fifteen to twenty grains being given daily. In the absorption or septic, or as it is ordinarily termed, the "hectic" fever of phthisis, quinine is believed to be of no use, and in its place salicylic acid is very strongly recommended. Thirty grains are given on the first day, then twenty or fifteen on the second or third days.

We have not space to go further in description of Jaccoud's methods. In fact we do not find in them anything radically new. His judgment upon the value of inhalations and compressed air is on the whole favorable, and in accordance with present views. With regard to pneumonic phthisis, a strong point is made as to the necessity of early, continuous, and vigorous stimulation. Throughout the course of treatment the use of alcoholic liquors is advised.

News of the Week.

Navy News.—Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service for the week ending August 22, 1885. Surgeon P. H. Bailhache, granted thirty days' leave of absence, August 15, 1885, Chairman of Board to examine Candidates for appointment as Cadet in the Revenue Marine Service, August 19, 1885. Passed Assistant Surgeon Fairfax Irwin, Recorder of Board, August 19, 1885.

The Third Annual Meeting of the American Rhinological Association will be held at Lexington, Ky., October 6, 1885. Papers and discussion will be devoted exclusively to the diseases of the nasal passages and their sequences. Officers for 1885: P. W. Logan, M.D., Knoxville, Tenn., President; A. DeVilbiss, M.D., Toledo, Ohio, First Vice-President; J. A. Stucky, M.D., Lexington, Ky., Second Vice-President; C. A. Sims, M.D., St. Joseph, Mo., Recording Secretary; N. R. Gordon, M.D., Springfield, Ill., Librarian. J. G. Carpenter, M.D., Stanford, Ky.; H. Jerard, M.D., East Lynne, Mo.; H. Christopher, M.D., St. Joseph, Mo., and E. F. Henderson, M.D., Los Angelos, Cal., Council. Information concerning the full programme, membership, papers, attendance, etc., may be learned from any of the above officers of the Association.

An Editor's Loss.—A fire in the office of the editor of the *New England Medical Monthly* destroyed his exchanges, a large quantity of matter ready for the press, books and manuscripts for the Medical History of Connecticut. We tender our condolences.

A Misinterpretation.—Dr. Garnett, of Washington, publishes in a contemporary journal the untruthful statement that The Medical Record is an ardent advocate of consulting with homœopaths. This shows how oversight sometimes leads the most polite into discourtesy. We have never advocated consulting with homœopaths, but only for the freedom and right of the individual to do so in certain cases.

The Professorship of Ophthalmic Surgery in the University of Gratz has been conferred on Dr. Blodig.

Progress of the Cholera in Spain.—According to information received by the National Board of Health, the following figures represent the diffusion and mortality of cholera in Spain for the period from July 4th to 17th, inclusive:

Provinces.	Cases.	Deaths.	Per cent. of mortality.
Albacete	35	13	37.1
Alicante	2,083	856	41.1
Castellon	1,367	639	46.7
Cuenca	467	205	43.9
Jaen	22	8	36.3
Madrid	1,076	602	55.9
Murcia	2,879	1,128	39.2
Tarragona	369	184	47.8
Teruel	81	33	40.7
Toledo	608	267	43.9
Valencia	10,220	4,979	48.7
Zaragoza	1,690	585	34.6
Total	20,897	9,499	....
Previously reported	28,044	12,347	....
Total reported.	48,941	21,846	....

The *Bulletin* also says that it is probable the epidemic has prevailed much more extensively than is indicated by the above figures, as the *Medical News*, published in Madrid, states in its issue of July 30th, that in one place more than one thousand certificates of death were found that had not been reported to the registrar. The same paper also states that in the vicinity of Valencia corpses are allowed to remain in some of the houses for more than forty hours, that the clothing and bedding of those who have died of cholera, which should be burned, are sometimes not taken from the houses for eight days, and sometimes not at all, and that the public vehicles of Alfafar, etc., which have their stand in the Plaza of San Augustine, carry corpses to the cemetery at a charge of forty-six reales, and immediately upon removing the bodies, load up with passengers for the return trip to the villages. The editor very properly urges the people to unite for protection against the scourge by the observance of sanitary precautions.

Pleasing to Americans.—In one of his letters to the *Philadelphia Medical Times* Dr. J. Milner Fothergill thus pays his compliments to American writers: "New books are certainly coming out here, but in sparse quantity compared to the legion springing up on your side of the water, many of which find their way over here, and are in repute. Not only are the products of the United States in drugs and chemicals taking the lead of home productions, but in literature they are threatening the old supremacy of England, or, rather, the United Kingdom: for Edinburgh always has held a good position in medicine, and when a Dublin man girds up his loins for a book, it is usually for a good one."

University of Vienna.—Drs. Hofmokl, Ultzmann, and Anton Wölfler have been appointed Extraordinary Professors of Surgery, and Dr. Mauthner Extraordinary Professor of Medical Chemistry.

Dr. A. Wynn Williams (London) has been elected a Corresponding Fellow of the Boston Gynecological Society.

The Academy of Sciences in Holland has awarded the Leeuwenhoek medal to Professor Ferdinand Cohn, of Breslau.

MEDICINE IN RUSSIA.—Dr. J. Lazarewitch, Professor of Midwifery and Gynecology in the University of Kharkoff, has been raised to the dignity of Emeritus Professor. Dr. Kusmin, formerly assistant to Professor Sklifasovsky, both in St. Petersburg and Moscow, has been appointed professor of the Hospital Clinic in the latter city. He has acted as editor of the "Annals of the Surgical Society of Moscow."

THE Government of India is making arrangements to have further investigations of a varied character, as to the essential cause of cholera, continuously conducted in India, under the direction of Dr. Douglas Cunningham. As the commission sent out under the direction of Professor Roy, by the Association for the Advancement of Medicine by Research, is now at work in the cholera-infected districts of Spain, the contributions made by England to the question, though somewhat tardy in their arrival, are likely to be important.

THE ACADEMY OF MEDICINE OF LIMA.—A report has been presented to the Free Academy of Medicine of Lima, Peru, by Dr. Villar, from the commission which had been appointed to investigate the cases of yellow fever in Callao.

A ROYAL MEDICAL PRACTITIONER.—Prince Ludwig Ferdinand of Bavaria, son-in-law of Queen Isabella of Spain, who obtained the degree of Doctor of Medicine at Munich last year, is now practising at Nymphenburg, Bavaria.

REMOVED FOR "OFFENSIVE PARTISANSHIP."—Dr. E. S. Elder, Secretary of the Indiana State Board of Health, has been removed for "offensive partisanship."—*Fort Wayne Journal of Medical Sciences.*

COCAINE is already being adulterated. Professor Kastenbine, reports the *Medical Herald*, analyzed a preparation sold by a Detroit chemist, and found it to contain two-thirds of boric acid.

AMERICAN DERMATOLOGICAL ASSOCIATION. — The Ninth Annual Meeting of the American Dermatological Association was held at the Indian Harbor Hotel, Greenwich, Conn., on August 26th, 27th, and 28th. Dr. W. A. Hardaway, of St. Louis, is President of the Association; Dr. W. T. Alexander, of New York, is Secretary.

FURTHER WITHDRAWALS FROM THE ORGANIZATION OF THE INTERNATIONAL MEDICAL CONGRESS.—Five of the officers of the Congress appointed from Chicago have withdrawn; also three gentlemen of Charleston, S. C.; two from the army, and several others living in different parts of the country. German and French medical journals echo the opinions expressed by the English medical journals, lamenting the introduction of ethical and local issues. Sir James Paget has written a letter to Dr. Hays, of Philadelphia, and Sir William MacCormac a letter to the *Boston Medical and Surgical Journal*. Both gentlemen intimate regret and surprise at the course taken by the American Medical Association. The invitation to meet in this country tendered in Copenhagen was believed, they say, to have been tendered in the name of the American profession. If it had been thought that a political issue would have been introduced, the invitation would not have been accepted.

THE FEVERS OF MINNESOTA.—In a paper on "Types and Phases of Fevers in Minnesota," read before the Hennepin County Medical Society, August 3, 1885, by Dr. Slagle, of Minneapolis, it was concluded that in Minnesota there are typhoid and typho-malarial fevers, but no types or phases of fevers peculiar to the State.

THE FOURTH ANNUAL ANNOUNCEMENT OF THE NEW YORK POST-GRADUATE MEDICAL SCHOOL is at hand. From it we learn that there were during the past year one hundred and twenty-nine matriculates. The school now has a hospital, which has already been substantially endowed, its own medical society, and its own journal. Sixty-three operations were performed in the hospital during the past season.

SANITARY ENGINEERING; A NEW FIELD FOR YOUNG MEN.—The School of Mines of Columbia College has recently established a course of study for the education of sanitary engineers. The course lasts four years, and is a comprehensive one, though apparently deficient in physiology and pathology.

EXIT THE BACILLUS OF SYPHILIS.—M. Cornil reports to the Académie de Médecine the results of the investigations by MM. Alvarés and Tavel upon the bacillus of syphilis (Lustgarten). They find a bacillus resembling Lustgarten's in normal secretions, and they incline to the opinion that it is identical with the so-called bacillus of syphilis.

DR. OLIVER WENDELL HOLMES.—We trust that Dr. Holmes will not feel sensitive on being reminded that this is his seventy-sixth birthday.

JOURNALISTIC CHANGE.—The *Medical Chronicle* has ceased its distinctive existence and combined with the *Philadelphia Medical Times*.

DANIEL'S MEDICAL JOURNAL is the title of a new journal just started by Dr. F. E. Daniel, late editor of the *Texas Courier-Record*. The *Journal* comes to us ablaze externally and internally. Dr. Daniel has a chivalrous mind and journalistic instincts. We wish him all success.

THE JEWISH RACE.—Disciples of Darwin have long wondered why Jews, who have been circumcised for thousands of years, are still born with a normal prepuce. M. Blanchard now announces to the Société de Biologie that many male Jewish infants are born without a prepuce. M. Landouzy affirms that flat-foot is very common among the Jews; M. Blocq affirms that scrofula, phthisis, hysteria, and severe neuroses are more than ordinarily common among the Jews, and that the race is in its decadence.

THE NEW BUILDING OF THE COLLEGE OF PHYSICIANS AND SURGEONS is to be located immediately opposite Roosevelt Hospital. Work has already begun upon it. The building, it is said, will be large and well equipped, but plain.

THE MISSISSIPPI VALLEY MEDICAL SOCIETY will meet at Evansville, Ind., September 8th, 9th, and 10th next. The railroads will return members at one-third fare. Hotel rates from $1.50 to $2.00 per day. This Society was formerly the tri-State Medical Society, comprising the States of Ohio, Indiana, and Kentucky.

Dr. Henry B. Sands has resigned his professorship on the Practice of Surgery at the College of Physicians and Surgeons. He will, it is said, still continue his clinical work in connection with the curriculum of the institution.

Dr. Samuel A. Green.—The Governor of Massachusetts has appointed Dr. Samuel A. Green, formerly City Physician and ex-Mayor of Boston, to the position on the State Board of Health, Lunacy, and Charity, formerly held by Dr. H. P. Walcott.

Resignation of Dr. Noyes from the Organization of the International Medical Congress.—Dr. Henry D. Noyes, of this city, has sent the following letter to the Permanent Secretary of the Committee on Organization of the International Medical Congress. "I beg to acknowledge your favor of the 19th ult., informing me of my appointment as First Vice-President of the Ophthalmological Section of the Ninth International Medical Congress by the committee which met at Chicago. This position I cannot accept, because, by so doing, I should assent to the action of the American Medical Association, which has thrust into the International Medical Congress a controverted subject with which the Congress has no concern, and has determined to exclude from all official positions the medical men whose convictions in this regard it disapproves of. I refuse to admit that the composition of the International Medical Congress should be in any way determined by the controverted points of the Code of Ethics of the American Medical Association. I also refuse to join in treating with neglect or disrespect honorable and eminent physicians, who do not accept all the restrictions of that Code about medical consultations. The right of the American Medical Association to take this course, can, I think, be successfully challenged; but for my own decision it is enough that I cannot concur with it, and that I feel sure that its pursuance will prove most hurtful to the Congress, in whose welfare, as you know, I have taken a deep and active interest. For the courtesy of the committee in tendering me this honor, I beg you to express my thanks."

The Drainage of Bellevue Hospital.—It is reported that twenty persons, employed as nurses and helpers in Bellevue Hospital, are ill from the effects of sewer-gas which has been permitted to enter some of the wards while plumbers have been placing new drain-pipes in the building. In the offices of the Health Department it was said that no reports of trouble from sewer-gas in the hospital had been received through official channels. The work of placing new drain-pipes in the hospital was begun on the recommendation of the Board of Health, and the plans of drainage are such as meet the approval of the sanitary officers.

The Verdict of the Court-Martial in the Case of ex-Surgeon-General Wales has, says a Washington correspondent of the Philadelphia *Medical Times*, caused somewhat of a sensation. It will be remembered that Dr. Wales was tried by court-martial and found guilty of inefficiency and neglect of duty, because he failed to discover the rascality of several of his clerks, by which the Government was swindled out of a large amount of money, said to be over a hundred thousand dollars. The court failed to connect Dr. Wales with any of the frauds, but convicted him on a technicality, and imposed what is considered here a very severe penalty, out of all proportion to the offence. The high professional character of the late Surgeon-General, and his successful labors for the advancement of the medical staff of the navy, did not avail him; in fact, they seemed to render his offence the greater in the eyes of the court, which apparently held the opinion that the duties of the Surgeon-General were simply to watch his subordinates and prevent their stealing. It seems by the confession of the principal criminal, the late chief clerk of the Bureau of Medicine and Surgery, that the frauds had gone on undetected for years under Dr. Wales' predecessors; but the court refused to go into the inquiry farther than concerned the latter's administration. To outsiders it looks very much as if Dr. Wales were the victim of a systematic persecution, of which the late Secretary of the Navy was the chief promoter. It is well known here that there was a violent personal antipathy between the two men, which may have been partly political, but is believed to have largely arisen from social antagonisms. The penalty imposed by the court is suspension from rank and duty for a period of five years. It is said that Dr. Wales' counsel will not rest satisfied with this verdict, but will appeal the case to the Supreme Court.

The Small-pox in Canada. — The mortality from small-pox in Montreal is on the increase. Most of the victims are French Canadian Catholics, who do not order their lives in obedience to sanitary rules, and are opposed to vaccination. Small-pox has for years been more or less prevalent in Montreal. In the five years ending with 1880 it caused the deaths of 2,549 persons in that city, and of these 2,146 were French Canadians. Of the fifty-six who died last week, fifty-two were French Canadians. The ignorance of these people seems to be on a par with the incompetency of the city authorities. Several cases are reported from Toronto and Quebec; but the authorities of the latter city deny the truth of the report. The City Council of Quebec are attempting to enforce the compulsory vaccination ordinance.

The Cholera in France.—Early in the week the cholera in Marseilles was rapidly increasing. Within forty-eight hours two hundred new cases were admitted to the Pharo Hospital, and during the same period two hundred deaths from the disease were reported within the city limits, besides fifty in the southern suburbs. At Toulon the disease was likewise spreading. The French squadron at Hyères has reported four deaths from cholera. Later reports denote some falling off in the mortality and morbidity of the disease.

Dr. Hire's Recommendation a Forgery.—It is reported that Dr. William H. Hire was appointed examining surgeon in the Pension Office at New Orleans on a recommendation purporting to be from Mr. St. Martin, of Louisiana, which turned out to be a forgery. Dr. Hire is under indictment for violation of Section 5,438, Revised Statutes of the United States, which refers to the collection or presentation of fraudulent claims against the Government.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 24, 1885.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

DIFFUSE LIPOMA—LOCAL ELEPHANTIASIS.

DR. A. JACOBI presented a baby, eight months old, the mother sixteen years of age. The anomaly for which he presented it was a moderate amount of swelling on the outer aspect of the lower half of the left leg, with the history that the swelling was noticed at birth, at which time it was smaller and softer than at present. Dr. Jacobi first saw the child two weeks ago, and the swelling had increased in size slightly since that time; it had not enlarged in circumference, but was raised a little more above the level of the surrounding tissue. The enlargement begins outside of the tendo-Achillis, about four centimetres above the malleolus externus, extending around the leg to about one-third of its circumference; the longitudinal diameter is about four and a half or five centimetres. It is not at all lobulated. Dr. Jacobi presented the case for diagnosis. There were only two things which, in his opinion, it could possibly be; first, diffuse lipoma; second, local elephantiasis. In the March number of *The Archives of Pediatrics*, last year, he published an article on congenital lipoma, and at that time collected a large number of reported cases, some complicated and others uncomplicated. One was complicated with spina bifida; one was very large, and spread over a very large portion of the body, quite diffuse, not capsulated at all as are lipomata in the adult. In a few cases the swellings were quite local. In one or two instances the tumors were removed without difficulty, but in others the cases terminated in death after attempt at removal. The diffused lipomata are characterized by not being capsulated, by beginning in the normal fatty tissue and growing locally, sometimes over a very small surface.

Another possibility in the case was that it was a local elephantiasis. He had seen congenital elephantiasis of such local character and in exactly the same neighborhood. He had seen it upon the dorsum pedis, and also upon the neck in the form of one or more heavy folds of skin; upon the foot in masses extending from one to one and a half inch, the transverse length being more than the vertical. He had seen one case in which the disease appeared in the lumbo-sacral region. One of the characteristic conditions which would aid in making a differential diagnosis was the fact that the skin itself is found hypertrophied, and it seemed to him that in the case presented the skin was hypertrophied. It was not movable over the fatty substance. If this be so, the case might be claimed as one of localized elephantiasis.

THE PRESIDENT asked if it might not be a sarcomatous growth.

DR. JACOBI said it was not malignant, like sarcoma, because it was not sufficiently circumscribed, and it was probable that it did not extend deeper than the subcutaneous tissues.

THE PRESIDENT said he had seen one case of congenital sarcoma which occurred upon the chin of a little boy, and remained as a movable thickening of the skin for a year and a half before it began to grow, and then it grew very rapidly until he died, at the age of two and a half years, with an immense sarcomatous tumor.

DR. JACOBI said that in his case the tumor was already of considerable size, and if it was malignant he thought it would have already assumed the shape which would have been expected if it had been sarcoma. The child was a very fat one, and that might perhaps arouse the suspicion of the swelling being originally lipomatous in character; at the same time many such babies were seen without like accumulations of fat.

DR. RIPLEY thought it unnecessary to hazard an opinion with reference to diagnosis when it was so easy to reach one by simply making an incision, removing a small portion of the growth, and examining it microscopically. Certainly if it was lipomatous the nature of the swelling could be thus readily ascertained, and no harm would be done by the procedure. So, also, if it proved to be a growth of another character, an operation for its removal could be completed.

DR. JACOBI said he thought he should remove the growth, and would probably have an opportunity to present it to the Society at some future meeting.

DR. W. GILL WYLIE presented a series of specimens (see page 227), illustrating eleven additional cases in which he had performed Tait's

OPERATION FOR SALPINGITIS.

DR. AMIDON asked Dr. Wylie in how many of the twenty-four cases in which he had operated the patients were distinctly hysterical.

DR. WYLIE said that probably one quarter or one-third might be classed as hysterical. He was inclined to the opinion that those patients were hysterical in whom the ovaries were in a condition of cystic degeneration without much disease of the tubes. In most of the cases the patients were absolutely bedridden. For the most part the operation was performed for the relief of physical pain. By no means did all the patients have dysmenorrhœa, and in the majority of cases in which dysmenorrhœa did exist it was associated with disease of the tubes.

DR. RIPLEY asked if, in the case in which there was uterine catarrh, with extensive pelvic adhesions, it was possible to cure the woman without resorting to such a heroic operation.

DR. WILEY thought it was not, as she had already been under treatment for a long time, had become an opium-eater, and was bedridden. Possibly the dysmenorrhœa might have been cured; but according to his observation, in all cases in which there had been what is called cellulitis, in the existence of which he did not believe, the tubes were usually involved, and he regarded it as the best procedure to remove them.

THE PRESIDENT asked if in the two cases reported as having died from the escape of septic matter into the peritoneal cavity, any effort was made to secure drainage.

DR. WYLIE said that in all of the cases except one, drainage was looked after carefully.

THE PRESIDENT asked what antiseptic precautions were observed.

DR. WYLIE said that the precautions consisted in the use of clean instruments, sponges, and hands, one assistant, shaving and washing the patient with bichloride solution (one in five thousand), and making the abdominal opening as small as possible. In only two cases had he washed out the peritoneal cavity, and in both the patient recovered.

THE PRESIDENT thought there were two cardinal points in abdominal surgery; first, cleaning and disinfecting the cavity after the operation; and, second, the institution of free drainage. From some recent experience he felt encouraged in the belief that the rate of mortality in abdominal surgery could be reduced still further than it had already been done. When a student he was taught that rupture of the bladder with the escape of urine into the peritoneal cavity was sure death. He recently saw a case of this kind in which a careful toilet was made with a pretty strong solution of bichloride of mercury, and there was no reaction whatever. The wound in the bladder was stitched to the edge of the external wound. He had also seen a case in which the peritoneal cavity became more or less filled with the gelatinous contents and septic matter from cysts, and in which the peritoneal cavity was filled with the warm sublimate solution (one to eighteen thousand) until it ran over, when the cavity was emptied, and this operation was repeated two or

three times until all septic material had been washed out and the cavity thoroughly disinfected. There were no evidences of sepsis after the operation, and no peritonitis occurred.

Dr. Wylie said that in private practice he had had twenty-two cases, with only one death. Of the eleven cases reported this evening, nine were in private practice, and in all the patients recovered.

Dr. C. H. Knight presented a specimen with the following history:

PERINEAL SECTION AND INTERNAL URETHROTOMY FOR STRICTURE AND URINARY FISTULÆ—HYPERTROPHIED BLADDER.

A. N——, forty years of age, Spanish, single. Patient had first gonorrhœa twelve years ago, and a second attack two years later. After last attack had several abscesses in perineum following partial retention. Was obliged to use catheter for a year or more habitually, and at times ever since. More than half the urine now passes through two perineal fistulæ, just to the right of raphe and one and a half and three inches in front of anus. Is obliged to urinate at least six times during the day, and rises twice or more times during the night. The urine is generally thick, and contains large quantities of pus. The perineum is very thick and inelastic, and is covered with scars of old abscesses, some of which have been incised, others having opened spontaneously. Meatus admits No. 24 (Fr.). At 4½ inches there is a contraction to No. 22, and No. 20 is arrested at 5 inches. No attempt has hitherto been made to close the fistulæ or divide the strictures. The fistulæ were laid freely open, but their point of communication with the urethra could not be discovered. They were traced backward a considerable distance, until the point of a probe could be felt separated from a small guide in the bladder by merely a thin layer of urethral mucous membrane, and then the urethra was opened by a free incision. From the same point, about five inches from the meatus, the urethra was divided with dilating urethrotome along the entire extent of its upper wall to No. 32, the meatus having previously been enlarged with a bistoury. Sounds were passed regularly for six months. The perineal wound gradually closed, until only a few drops of urine came through the false passage, and frequently none at all would appear for several days continuously. Fifteen months after the first operation the patient had a severe fall, and in a few days an abscess formed near the anus, behind the perineal fistula. The opening of this abscess resulted in a marked increase in the proportion of urine passed by the perineum. No sounds had been used for six months, and slight recontraction was found with No. 30 bulb at about five inches. Patient was very anxious to have fistula closed, and the first operation was practically repeated, the urethra being divided so as to admit No. 36 sound easily to bladder. The patient recovered from this operation as rapidly as from the first. The perineal wound quickly closed, and after the tenth day no urine passed by the perineum for a period of five weeks, when a few drops appeared, without the formation of a fresh abscess. This occurrence greatly depressed the patient, and soon after, having had a serious quarrel with a business associate, he took an enormous dose of potassium cyanide and died in a very few minutes.

The specimens, removed at the New York Hospital by Dr. Thayer, of the House Staff, show the effect upon the bladder of prolonged urethral obstruction, a large periurethral abscess in the deep urethra, and the appearance of the urethra two months after an internal urethrotomy. The kidneys and other viscera showed no evidence of disease, but the stomach was intensely congested from the action of the poison. The vesical wall is much thickened, the hypertrophy being most marked in the muscular coat, and the capacity of the bladder seems to be diminished. The mucous lining is also somewhat thickened, but is smooth and free from erosions. The prostate gland is somewhat hypertrophied. Just behind the junction of the prostatic with the membranous urethra, and to the right of the veru montanum, are two fistulous openings, separated by a band of tissue one-eighth of an inch in width, and entering the cavity of an abscess, which partially surrounds the membranous urethra and extends backward toward the prostate gland. Half an inch in front of these two fistulæ, and communicating with them rather than with the abscess cavity, is the small opening of a third fistula, which runs just beneath the mucous membrane. In the median line of the floor of the membranous urethra is the mouth of a fourth, which opens directly into the abscess. This is the larger of the fistulæ and readily admits a No. 28 (Fr.) sound. The smallest will receive only a small probe. The capacity of the abscess is estimated at about two drachms. The pendulous urethra shows along its upper wall a "cicatricial splice," the result of the internal urethrotomy, about one-third of an inch wide at its widest part. Their position and the remoteness of the fistulous openings from the point of urethral contraction suggest the possibility of their having been caused by instruments, and there is, moreover, a history of rather rough handling and of profuse hemorrhages on several occasions after instrumental interference. An interesting point in the clinical history of the case is the re-establishment of vesical tolerance after removal of urethral obstruction by the internal urethrotomy, notwithstanding the evidently reduced capacity of the bladder. Previously the necessity of emptying the bladder had been frequent and urgent; after the operation the intervals between the acts of urination were of natural length and the bladder seemed to be under perfect control.

Dr. Amidon asked if the hypertrophy of the bladder had anything to do with the maintenance of the perineal fistulæ.

Dr. Knight thought it doubtless had, and was also of the impression, from the position of the fistulæ, that they were produced by instruments.

The President remarked that he never fully appreciated how little was known concerning the introduction of steel sounds into the bladder until he began teaching.

Dr. Ripley said he once had a patient at St. Francis' Hospital, sixty years of age, who had not passed urine through the urethra for six years. He performed external perineal urethrotomy, and the fistulæ closed.

The President believed that in the majority of cases the fistulæ would heal after perineal section.

FIBRO-SARCOMA OF THE NASO-PHARYNX.

Dr. R. P. Lincoln presented a specimen, removed June 23d from the naso-pharynx of a man, seventeen years of age, from whom he removed a similar growth eleven months ago and presented the specimen to the Society in October last. The second specimen was chiefly interesting on account of the method of treatment. In the first case he removed the tumor by the use of the galvano-cautery écraseur, intending to cauterize the stump thoroughly until the seat of the growth was entirely destroyed. Although he had the assurance of the patient that he would return and have the stump cauterized, he failed to keep his promise, and Dr. Lincoln had opportunity to make only occasional applications. Finally the new growth became so much enlarged and gave the patient so much inconvenience that he submitted to another operation, and Dr. Lincoln hoped to be more successful than formerly in obtaining opportunity to repeat the caustic applications to the stump. The tumor presented was quite vascular, as was the case of those of reproduction, the vessels increasing in size with each new growth. It filled the right nostril and the post-nasal cavity, and had a broad attachment. The wire grasped the tumor well up to its insertion. The case illustrated the necessity of repeated cauterizations of the stump after removal of such a neoplasm.

Dr. Jacobi asked Dr. Lincoln if in most of his cases the patients were young persons.

Dr. Lincoln replied that in most of the cases the patients were under twenty years of age. A patient, however, whom Dr. Knapp had sent to him to-day, was a man probably forty-five years of age.

FRACTURE OF THE OCCIPTAL BONE.

Dr. W. P. Watson presented the occipital bone, removed from a man, nineteen years of age, who received an injury of the head, probably from a stone. It was a coroner's case, and it was to the coroner he was indebted for the specimen. The man was hit on a Wednesday. He went to his work on Thursday, worked all day, and also on Friday and Saturday. But Saturday evening he complained of headache, went to bed, sent for a physician, who found the patient unconscious. The subsequent clinical history of the case Dr. Watson had been unable to obtain. At the autopsy there was found in front of the occipital protuberance a soft spot in the scalp. On turning back the scalp there was found a well-marked ecchymosis about an inch and a half in diameter. On removing the calvaria there was found a fracture, commencing at the occipital protuberance and extending downward three and a half inches, involving a portion of the margin of the foramen magnum on the right side; on the left side it did not extend down to the margin of the foramen. There was marked congestion of the brain and meninges. When the patient was admitted to St. Francis' Hospital, Hoboken, on Tuesday, he had tonic spasm, the pupils were irregular, sometimes responding to light and other times not; the bowels and urine normal; the patient was unconscious. About two or three hours before death there was quite a profuse hemorrhage from the nostril.

Dr. Van Santvoord said he had had opportunity to make several autopsies in cases of this kind, and in all death occurred from surface hemorrhage; the fractures themselves were apparently innoxious.

Dr. Wylie referred to the case of a young man who received an injury of the head, had hemorrhage from both ears followed by serous discharge for ten days, and also hemorrhage from the pharynx. He gradually recovered without special treatment, except rest.

The President remarked that hemorrhage from the ear was not necessarily an indication of fracture of the base of the skull.

Dr. Wylie said no, but there was in addition a discharge of serous fluid from the ear for ten days.

The President referred to a most remarkable case, the specimens from which were in Wood's Museum, that of a sailor who fell twenty feet and struck square upon his buttock and received no fracture at all except at the base of the skull, where there were twelve different fractures caused by displacement of the bones of the spinal column upward.

CATARRHAL ULCERS OF BOTH VOCAL CORDS.

Dr. Van Santvoord presented a specimen illustrating catarrhal ulcers of the vocal cords, resulting from ulceration of the larynx accompanying measles. The patient was an infant, eight months and ten days old at the time of death, and an inmate of Randall's Island Asylum. It was suffering from the early symptoms of measles when admitted. The eruption developed on the second day. On the second day of the eruption the child began to have cough of croupy character, preceded by severe pharyngitis. On the fourth day of the eruption there was entire loss of voice. The child died of extensive broncho-pneumonia and bronchitis.

At the autopsy, in addition to the broncho-pneumonia and bronchitis, the larynx was found to be very much congested, and at the posterior half of each vocal cord there were found ulcers which appeared as if covered with slough. He had had occasion to make a number of autopsies in which there were broncho-pneumonia and bronchitis following measles, but as a rule he had not examined the larynx unless there had been some special evidence of laryngeal trouble before death, and had not before seen the condition illustrated in his specimen. On looking up the literature of the subject, however, he found that it was not very uncommon. Rilliet and Barthez stated that about one-half of the fatal cases of measles showed ulcerations of the larynx. In this case there were no symptoms of laryngeal obstruction.

FATTY DEGENERATION OF THE HEART—CONCENTRIC HYPERTROPHY.

Dr. J. H. Ripley presented the heart removed from the body of a man, sixty-seven years of age, who, one year ago, weighed two hundred pounds. His history showed that he had never been sick to any extent until last July; he had never had either rheumatism or syphilis. Last August he had an attack of diarrhœa accompanied with abdominal pain. At the end of a week Dr. Ripley saw him and found him suffering from intense pain over the hypochondriac region, but at that time the diarrhœa had ceased. There was a great deal of tenderness over the region of the liver, and the area of hepatic dulness extended four inches below the free border of the ribs. The temperature was 101° F. The constitutional symptoms, except the pain in the hepatic region, were not very grave. He was struck with one symptom and that was the great frequency of the pulse, together with its extreme feebleness and irregularity—one hundred and sixty to the minute, irregular, and at times almost imperceptible. There was marked turgescence of the cervical veins; there was œdema at the base of both lungs. Dr. Ripley diagnosed the acute trouble as perihepatitis. At the end of a week the patient recovered from the acute attack, and so far as the bowels were concerned they were constipated afterward. He did not rally thoroughly from the attack, and little by little his dropsy increased, both pleural cavities became involved, and later he had ascites and extensive anasarca. All treatment failed to reduce the increasing dropsy. In November Dr. Ripley punctured the cellular tissue of the lower extremities and water drained away in large quantities. The pleural cavities became free, also the abdominal dropsy and anasarca disappeared. The pulse, however, continued rapid, irregular, and feeble, at times two hundred to the minute. The patient suffered from dyspnœa and anorexia principally. After he had watched the case for a time Dr. Ripley made the diagnosis of probable fatty degeneration of the heart, and based it upon the condition of the stomach, with the great rapidity of the heart's action, the condition of the veins of the neck, and the dropsy. Up to November 1st, despite very careful examination, no cardiac murmur was discovered. Later on there commenced a perceptible murmur at the apex, which was not transmitted, and still later on, a murmur was heard at the base of the heart. By January 1st the patient had so far recovered that Dr. Ripley discontinued his visits, although there remained considerable dropsy, but the patient had a fair appetite. While Dr. Ripley was attending the patient there was no evidence of Bright's disease. Not long after he ceased his visits the patient got worse, but went under the treatment of an irregular practitioner, under whose care he remained until death. As near as Dr. Ripley could learn, the man had general dropsy, which was removed by hypercatharsis two or three times. The patient gradually emaciated until he did not weigh more than one hundred and forty pounds, and his skin always had a yellowish, saffron color.

A partial autopsy revealed extensive infiltration of the cellular tissue with serum; three pints of serum were found in the abdominal cavity; the pleural cavities contained about six quarts of fluid; the pericardium contained not more than one or two drachms of fluid; the liver was considerably enlarged, its capsule thickened, and on section it resembled ordinary nutmeg liver; the kidneys were covered with an unusual quantity of fat, the capsule was adherent, and the cortical portion thick-

ened; the spleen was about the size of a pullet's egg, contained two lobes which were attached to each other by a capsule; the lungs had become carnified at the bases, and there were old pleuritic adhesions.

The organ chiefly interesting was the heart. The pericardium contained an unusual quantity of fat. The aortic valves were very much thickened, shrunken, and apparently insufficient. The cordæ tendinæ of the mitral valve were thickened and shortened, and the valve itself was shrivelled, and the orifice was in a state of stenosis. The walls of the left ventricle were very much thickened; the capacity of the ventricle was very much lessened; it would not contain more than one or two drachms of fluid. It was a case of concentric hypertrophy. The tricuspid valves were thickened, and there were some fibrinous deposits on the anterior suface. There was but slight atheroma of the aorta. The coronary arteries were healthy.

On microscopical examination of the muscular tissue many of the primitive fasciculi were literally filled with small fat-globules, and the striæ were indistinct. Dr. Ripley took pains to examine the right ventricle and both auricles, and found that the muscular tissue in all of them had undergone extensive fatty degeneration, more marked in the right than in the left ventricle, and the auricles were not much better.

He presented the case because, although fatty degeneration of the heart was very common, still its clinical history had not been written up very extensively. In addition to the clinical history already given, it might be added that the arteries throughout the body did not appear to be atheromatous.

The Society then went into executive session.

British Medical Association.

FIFTY-THIRD ANNUAL MEETING.

Held at Cardiff, on Tuesday, Wednesday, Thursday, and Friday, July 28, 29, 30, and 31, 1885.

REPORTS OF SECTIONS.

(Continued from page 218.

PUBLIC HEALTH SECTION.

THURSDAY, JULY 30TH—SECOND DAY.

DR. DAVIES in the Chair.

MR. FRANCIS VACHES, of Birkenhead, read a paper on

SUMMER DIARRHŒA OF CHILDREN, ONE DISEASE OR MANY.

He pointed out that in 1883 there were 15,000 deaths, and in 1884 25,000 deaths from diarrhœa. The number of deaths in the latter year was more than half the total number from the two chief zymotic diseases. After dealing with the question at considerable length, Dr. Vaches found it impossible that the immense infant mortality referred to diarrhœa every summer could be due to one disease.

DR. MARTIN, of Bolton, thought that summer diarrhœa was often due to altered quality of the milk.

DR. WIGHT, of Southport, thought the health returns should be more discriminating.

DR. SWETE, of Worcester, said it was very difficult for the medical officer to get proper returns in such a question as this.

DR. PAINE, of Cardiff, said the difficulty of giving correct returns of the causes of death was very great. The Registrar-General had recently called attention to the number of cases in which death was put down to diphtheria, which he believed was due to careless diagnosis. The same remark applied to diarrhœa, which was a symptom and not a disease. First of all, diet was a common cause of diarrhœa, and then came temperature and rainfall, which, taken singly or together, might produce disease. He inquired into the question of one hundred and ten deaths from diarrhœa, and in only one case had the child been breast-fed. Cow's milk should not be used for at least fourteen days after calving. In July, August, and September there was the question of temperature which gave a proclivity to disease. In 1883 the mortality from diarrhœa in the eastern part of Roath was one hundred per cent. more than in any other part of the district, and there were imperfect sewers there, which much favored zymotic diseases. The average rainfall in Cardiff was forty-three inches, and last year thirty-six, so that more diarrhœa prevailed. Disinfectants had been poured into the sewers, and this appeared to have much lessened the mortality from cholera.

SURGEON-MAJOR PRINGLE thought that much of the milk brought to market was unfit for the food of children.

DR. DAVIES thought that diarrhœa was, to a certain extent, a generic name, but he could not admit that all the diseases which came under his treatment were merely symptoms. Some of the diarrhœa cases he said had cow's milk, others bread and water, and lived in houses under £20 rental.

DR. BULLARD, of London, said he had tried to get to the bottom of this question, but unfortunately had not been well enough supported by the members of the profession.

DR. PAINE had noticed at one time, when cholera was prevalent in Cardiff, that it did not occur among the Irish infants, whose parents did not buy cow's milk, but fed their children on oatmeal and water.

DR. DAVIES noticed that Irish women nursed their own children.

DR. DRYSDALE, of London, said that there could be no doubt that the cause of many of the deaths from diarrhœa was the drinking of milk and other fluids containing organisms which were true poisons. These were particularly lifelike in the hot, summer months. Good milk was in many instances the best cure for diarrhœa in children, but the milk must in many cases be boiled, and of course the bottles used in infantile feeding maintained scrupulously clean. A large number of children of the poor in London died from diarrhœa through being brought up by hand, and in 1847, when he was on a tour in Ireland, at the time of the famine, children were carried off in large numbers from the diarrhœa caused by starvation.

DR. MARTIN, of Bolton, read a paper on

OVER-PRESSURE IN SCHOOLS AND HOME LESSONS.

Over-pressure injures the health of children, produces misery at home, both for parents and children, almost every night. Children, in order to keep pace with the present code, have to pore over their lessons (in some instances) until ten, eleven, or twelve o'clock at night (as do pupil teachers, who should be growing in body and mind). Next morning the child goes to school without being able to eat its breakfast; the effect of this upon the brain and nervous system takes away the appetite, enervates the child, and stunts its growth; then follow headaches, vomiting, nervous debility, brain fever, talking and walking about in the bed-room in the night, St. Vitus' dance, curvature of the spine, heart disease, myopia, spitting of blood, and in some instances convulsions and death. I have personally seen all the above in my own district. The dread of the examination, of the inspector's visit, the anxiety to gain a prize, or the thought of not being able to pass the examination, so as to leave school in order to work for a livelihood, have each and every of them a share in the production of mischief. The master or matron is worried and in misery about the grant, the inspection, the school peace, and the managers; and to aid in increasing the number of passes and the augmentation of the grant, the managers or teachers in some instances send for all children (even from houses where there exists infectious or contagious disease) to be present at the examination, no provision being made in the Education Act for the

counting of those as present at the examination who have been kept from school for the protection of the public health. In reference to schools, light, position, ventilation, and proper warmth are all essential to the health of children and teachers. I now repeat what I stated on May 4, 1883, viz.: "It is very important that children who have a capacity for education in the higher branches of knowledge should have every opportunity of gaining such knowledge, and that the State should assist. It is also very necessary that a child or young person be at school five or six hours a day, but I often see children whose health is injured by over-study or brain work; such children might very properly be excused what teachers call home work, to enable them to learn domestic duties, and assist their parents or guardians. At the same time it would make them more healthy and more fitted to the wants of the country."

Since I read my paper at Liverpool in 1883, home lessons have ceased at some schools for very young children, and parents now know that home lessons cannot be insisted upon and are illegal. The examinations have been less rigid; but still the code is too high, and as it is monstrous to imagine that all children can be brought up to the same level, the boasted one hundred per cent. of passes is a very strange thing. The head master or mistress of every school ought to have the option of removing from examination, at least, seven per cent. of those who can give their whole time to school, and fifteen per cent. of "half timers," who have not the same privileges as others; this, with an allowance for children kept from school for the protection of the public health, would mitigate to some extent the evils existing. The special committee of the London School Board admit that they have not had the advantage of practical medical testimony when speaking of increased physical benefit. But it has been stated that "throughout the country the voices of managers, teachers, and employers of labor bear witness to the diminished vigor and attenuated limbs of the children of our working population, and ask if there is no way of opening the eyes of our education theorists to the bitter and terrible wrongs inflicted on our young." Professor T. Pridgen Teale, a very high authority, says he is "simply horrified at the refinement of human slavery and torture invented and carried on in this civilized country." The question of ill-fed children is a very important one, but of all the cases that have come under my care, only two could be said to be due to improper feeding, and not one to want of sufficient food; the punishment must be severe where a child is crammed in the head, and nothing in the stomach. Teachers also come in for a full share of torture. Three teachers have died in the Bolton District within a very short time, all comparatively young; one of them died on the very day of the examination of his school. It is a well-known fact that myopia is unknown among the wild tribes. Some time ago, at Berne, Professor Pflüger, a great authority, gave it as a fact that more than one-half of forty-five thousand children examined in Germany, suffered from defective vision; in some schools those suffering from myopia, or shortsightedness, amounted to seventy or eighty per cent., and the commission actually found twenty per cent. of the boys, and from thirty to forty per cent. of the girls, suffering from curvature of the spine. The most enthusiastic devotee of excessive education would regret to see the above state of things take the place of the indomitable pluck, energy, and endurance of our forefathers.

Dr. Swete, of Worcester, said that there could be no doubt that over-pressure in schools was due to the way in which parents were pushing on their children to get on in the world, and, as an inspector said in his district, the children had too much brain food and too little stomach food. In Scotland, where children studied well, they were fed on oatmeal porridge and milk, but in English towns the children got scarcely any phosphates and too much brain work for their stamina.

Dr. Drysdale, of London, said it was an axiom in his mind that children could not be better educated than they were fed. The chief point in education was first of all to give good nutrition, and he was convinced that the State system of education, as at present in vogue, would break down, unless the supply of children were greatly reduced, so that the number to be educated did not exceed the capacities of the capital of the country to feed, clothe, and house adequately. It would be possible for the State to insure comfort and education to all born into it, but if it did this it was bound, as J. S. Mill said to us, to see that no one was born without its consent.

Surgeon-Major Pringle said he was much struck on returning to this country after an absence of twelve years, to find so many boys and girls wearing spectacles, and suspected this must be caused by the over-pressure in Board schools.

Dr. Mantle read a paper on

INFECTIOUS SORE THROAT WITH RHEUMATISM.

He exhibited some microscopical slides, showing the organisms which had been, in his opinion, the origin of this disease, which appeared to be epidemic and contagious at present in some localities.

Dr. Swete, of Worcester, read a paper on

A DANGER WITH CONSTANT WATER SUPPLY.

He showed that suction brought sewage and other deleterious matter into the water-pipes. They must, therefore, try to prevent the suction. If there was no vacuum in the water-pipes there could be no suction. He exhibited a valve for placing on the highest point on the water-pipes, which valve would let the air in without letting the water out. This plan was approved of by many of the members of the Section.

The meeting then adjourned.

FRIDAY, JULY 31ST—THIRD DAY

Dr. Davies, of Bristol, in the Chair.

The first paper was read by Dr. C. R. Drysdale, of London,

ON THE INFLUENCE OF COMFORT IN LOWERING THE DEATH-RATE.

The author said that this point had been first discussed clearly, as far as he knew, by Dr. Villermé, of Paris, in 1832, who had showed that in Paris the death-rate of persons in easy circumstances between the ages of forty and fifty, was only 8 per 1,000 per annum, while it was 18.7 per 1,000 among persons of humble circumstances. And that the death-rate in the poor quarter, twelfth arrondissement of Paris, was 1 in 15 persons as against 1 in 65 in the rich quarter, or second arrondissement. It had recently been shown by M. de Haussonville in the *Revue des Deux Mondes*, of 1884, that there were three times as many children to a family in the twelfth, as in the second arrondissement. The remarkable statistics of C. Ansell, junior, of the National Assurance Society of London, had showed that of 100,000 born of the professional classes and gentry at a given age, 80,000 were alive, as against 65,000 of the general population. The present statistics of the various districts in London was a complete confirmation of these statistics of rich and poor mortality. The rich suburb of London, Hampstead, had a very low death-rate, 11.50 per 1,000 per annum, as against a poor quarter, St. George's parish, Whitechapel, with a death-rate of 26 per 1,000. Here, again, the birth-rate was, as in Paris, in the inverse ratio of the death-rates. The birth-rate of Hampstead was but 22 per 1,000 as against 40 per 1,000 in the Whitechapel parish. His own hospital, the Metropolitan Free Hospital of London, was in the Whitechapel district, and he had found that the average of children to a family among

his married female patients over forty-five years of age was more than seven children, whereas the number of children among the professional classes in Paris was not two to each family. The death-rate of the children in Whitechapel among the poor was often twenty five to thirty per cent. in the first year of life, against eight per cent. among the infants of the well-to do classes in England and France. His conclusion, therefore, from all these glaring facts, was that the further lowering of the death rate among the poorer classes would be an impossible matter so long as families were so large in that class. If only the birth-rate among the classes with the lowest wages was as low as 25 per 1,000 instead of 40 per 1,000, he saw no reason why the death-rate of England and Scotland might not fall to 12 per 1,000, as it was in well-fed New Zealand. The State would have to discourage the production of families of more than four children, sooner or later.

Dr. Paine, of Cardiff, agreed with the opinion put forward by Dr. Drysdale, as to the superior mortality of the poor, although it was remarkable that sanitary efforts had reduced the death-rate among the poor in a greater ratio than it had among the well-to-do in Cardiff. The statistics of London cited were true of the poor Irish population of Cardiff, which was next door to mendicancy in many cases. The birth-rate in Cardiff was 41 per 1,000, yet the infant mortality under one year was rather low. He had often said that the natural death-rate of a population should not exceed 15 per 1,000, and thus in Cardiff there were at least 5 lives more per 1,000 annually that should be saved, which future laborers in hygienic science must work for.

Dr. Davies, of Bristol, said that poverty was clearly a factor in causing high death-rates, and in Bristol that was because the zymotic diseases attacked the children of the poor, who crowded into small house accommodation so much more than did the well-to-do classes. In Bristol the poorer classes had good food; but they were exposed to cold, and the children were not nursed carefully enough. There was a charitable association in that city which did its best to remedy this misfortune of the poor. The death-rate of Bristol was only 2 per 1,000 lower than that of Clifton, which was very consoling. He did not see how the poor could be enjoined to have smaller families. The evil to be combated was the Poor Law system, which made the poor thoughtless, so that, unlike the professional classes, who postponed their marriage-day until the man was thirty, the poor married at twenty, and in eight years had five or seven children to provide for. The poor should not be taught improvidence by the law.

Dr. Pringle said that in Lewisham, London, where he resided, there was an immense amount of overcrowding, which was caused by the imperfect supply of house accommodation and the very high rents the poor had to pay.

Dr. Rice Morgan, of Swansea, said the paper covered a most important ground, and related to the age, distribution of the population, and wealth of its members. Poverty and discomfort were not always synonymous, for many operators who were well off lived in wretched tenements to save money in rent.

Dr. Drysdale, of London, said that he was glad to find such eminent public officers acknowledging the gravity of the question. For his part, he had long been convinced that the next move in sanitary science must be in the direction of the State discouraging the multiplication of misery by means of those large families which no one wished to see, and least of all the parents. If the birth-rate of Brompton was only 19 per 1,000, against 40 per 1,000 in Whitechapel, it was clear that intelligence might alter that, and doubtless in the near future sanitary science would, in the words of the great economist, J. S. Mill, come to look upon the producing of large families in any class in European countries in the same way as they now looked on drunkenness or other preventable cause of death and misery.

Dr. Brindley James read a paper entitled "Are Coroner's Juries Necessary?" He contended that such was not the case, because in France, Belgium, and other countries, the system of the *médicin des morts* was a far better guarantee against crime than our jury system. To prove this he alluded to the Becarmi poisoning case in Brussels, some years ago, where a husband poisoned his brother-in-law from sordid motives, with the assistance of his brother and his wife. The poison used was nicotine, and the *médicin des morts* who investigated the case detected the poison in the vomited matter, while had this case been put before a jury the man would have got off. The publicity of English juries was extremely painful to the relations of many poor people who had accidentally died, and who were maligned in the daily papers after death because they had occasionally used alcohol. He was of opinion that some system of the kind should replace the happy-go-lucky system in England.

Dr. Drysdale, of London, spoke in praise of the French *médicin des morts*, who came at once on a death occurring and thus made a clear piece of statistics in case of children dying within the first six weeks, many of which did not appear either as births or deaths in English mortality statistics.

Dr. Davies said he had made a suggestion some years ago to the authorities that there should be two coroners in each district, one of whom should be a medical man.

Dr. James thanked Dr. Drysdale and Dr. Davies for the approval they had expressed of his views, which he felt very strongly.

Dr. J. Lloyd Roberts read a paper on "Epidemic Pneumonia."

Dr. Might read a paper entitled "Remarks on the Present Management of the Sanitary Medical Service, with Suggestions for its Improvement." He was strongly in favor of a more educated class of the community being the directors of the sanitary board in each city.

The Section then separated with a vote of thanks to Dr. Davies, of Bristol, for his most able and courteous conduct in the president's chair.

Dr. Davies said this was the most self-denying of all the sections, since it did its very best to get rid of the very diseases on which medical men lived.

SECTION OF PHARMACOLOGY AND THERAPEUTICS.

Wednesday, July 29th—First Day.

This Section opened with an address by the President, Professor Fraser, of Edinburgh, who began by complimenting the Association for forming the Section, of which the present is only the second year, and then preceeded to administer a further compliment—some would say the puff direct—to the *Journal*. He then dwelt on the propriety of separating pharmacology from other branches of study, and urged that there ought to be at every great medical school a properly equipped laboratory for research on this subject. He held such laboratories to be as necessary as they were admitted to be for the prosecution of chemistry and physiology.

Professor Leech, of Owens College, then read his paper on "The Duration of the Action of Medicinal Substances," a subject which seemed to interest the Section less than might have been expected, though some interesting remarks were made, and the paper when published will be worth perusal.

Then came a discussion on

SUBCUTANEOUS MEDICATION,

introduced by Dr. Talfourd Jones. In connection with this a paper was read on the "Subcutaneous Use of Quinine," by Dr. L. Aitkin, who also contributed interesting remarks on "Ergotine in the Hemorrhage of Typhoid Fever." Dr. Spender and several others contributed remarks, but altogether the discussions on the first day scarcely came up to the expectation that had been formed when the arrangements were made for this Section.

THURSDAY, JULY 30TH—SECOND DAY.

DR. E. LONG FOX, of Clifton, opened a discussion on the "Action of Diuretics," in which several gentlemen took part.

The President, DR. FRASER, F.R.S., read a paper on the "Action and Uses of the Digitalis Group, with Special Reference to Strophanthus Hispidus." He related his experiments with the last-named drug, with which he seems to have been occupied for a considerable period. There is no doubt about its very powerful influence upon the heart, and it will probably come into use, but at present very few persons seem ever to have seen it or heard of it. The reporter only met with two gentlemen in the Section who were acquainted with it, and both of them were professors. This being the case, there could be but little discussion, but a good deal of interest was excited by the demonstration which followed, by DR. STOCKMAN, of Edinburgh, of the action of strophanthus hispidus on the heart of a frog by means of an apparatus which recorded the tracing so that it could be carefully compared with the tracing produced by the heart's beat immediately before the application of the drug.

The Section was asked to consider a proposal of DR. BALTHAZAR FOSTER, made through the Collective Investigation Committee,

THAT THIS SECTION SHOULD DISCUSS NEW REMEDIES, AND MAKE A SELECTION FOR FURTHER INVESTIGATION IN CONJUNCTION WITH THE COLLECTIVE INVESTIGATION COMMITTEE.

THE PRESIDENT rather threw cold water on the project, remarking that he did not himself expect much good to result from a superficial investigation such as that proposed, but he would be happy to hear the opinions of those present. No one responding to this invitation, he then asked Dr. I. Owen to state on behalf of the Collective Investigation Committee the exact nature of their proposal.

DR. ISAMBARD OWEN thereupon explained the project, and proposed that the Section should appoint a subcommittee to co-operate with the committee he represented.

THE PRESIDENT again invited an expression of opinion, but there was no response. There were not a dozen members in the room; none of them seemed to care one way or the other. The question was therefore put from the Chair whether such a sub-committee should be appointed; some in very weariness held up their hands and the proposal was declared carried. Then followed the naming of the committee; the President declined to serve, as did one or two others, but eventually the two Secretaries and Dr. Murrall were appointed.

A list of drugs was next proposed, but the Section seemed too weary to consider them, and a proposal to leave the selection to those who undertook the investigation was welcomed as a relief, and though not formally put was allowed to pass, and the subject dropped.

DR. NORMAN KERR read a paper,

OUGHT ALCOHOL TO BE PRESCRIBED, AND HOW?

It was anticipated that this would lead to some discussion, Dr. Kerr being known as a thorough-going advocate of teetotalism; his paper, however, was a very moderate one. He by no means advocated a refusal to prescribe alcohol, but insisted that it should only be given for definite purposes and in duly adjusted doses. As he concluded only a few minutes remained for discussion, and no one seemed desirous of occupying them by either controverting or supporting the views advanced.

If this day's proceedings were to be considered as a test, it must be acknowledged that the Section scarcely justified its formation; the real work could have been done elsewhere.

FRIDAY, JULY 31ST—THIRD DAY.

A debate had been arranged on "General and Local Anæsthesia," and was opened in a very long and extremely uninteresting paper by DR. DUDLEY BUXTON, who waded through it in a most tedious manner, but steadily persisted in reading every word, though his audience became smaller by degrees and beautifully less, scarcely half a dozen being able to sit it out to the end. He occupied rather more than an hour and a quarter, although every copy of the programme stated that no paper in the Sections must exceed fifteen minutes. He confined himself principally to general anæsthesia, the causes of death, the differences between ether, chloroform, and other substances employed, and the manner in which they acted, with many other points which will probably be interesting to read, but were positively painful to listen to as they were droned out. At last he sat down, and the President rose to state that Professor Cheyne, who had promised to attend, had been prevented, but had forwarded a statement of his views in a printed pamphlet. This pamphlet contained a reprint of a lecture to the Professor's surgical class, and had already been printed in the *Practitioner* with prefatory remarks. The Professor had caused a copy to be given to every one entering the room, nevertheless the President decided to have it read. This was the sequel for a further exodus of the long-suffering members, and great indignation was expressed afterward at the conduct of the President in thus wasting the time, which it was freely said he would not have permitted had the author not been a Scotchman and a colleague.

Mr. Bailey, Dr. Redwood, Dr. Talfourd Jones, Dr. Bampton, and another or two made a few remarks, after which Dr. Buxton got up to reply and occupied a considerable portion of the remaining half hour. Only a few minutes were then left, and any other papers had to be taken as read, as the President declared the work of the year to be concluded.

SECTION OF OBSTETRIC MEDICINE.

THURSDAY, JULY 30TH—SECOND DAY.

(Continued from page 215.)

The next paper was by MR. LAWSON TAIT, of Birmingham, and was entitled

MODERN TREATMENT OF UTERINE MYOMA.

Mr. Tait referred to the advances which had of late years been made in pelvic and abdominal surgery. He then introduced the present subject by narrating two cases. They were sisters, and came to consult him at the same time. One was thirty-eight years of age, unhealthy and anæmic in appearance; the other was thirty-six years of age, and seemed to be in perfect health. To his surprise the latter announced herself as the patient. She had a uterine myoma which reached to the ensiform cartilage. She had been advised by several medical men to let it alone and have nothing done for it. When he had examined this patient the sister expressed her wish to be examined also. He accordingly examined the elder one of the two and found her to be also suffering from uterine myoma. It was a small one, and she had been treated by a pessary. Thus, said Mr. Tait, he actually had at the same time in his consulting room, two women, sisters, both of whom suffered from uterine myoma. The elder had but a small tumor but had been much reduced by hemorrhage; the younger had what was virtually—from its rapid growth—a malignant tumor reaching to the ensiform cartilage. In his opinion, neither of these women could have lived five years. Mr. Tait's treatment for uterine myoma was the removal of the uterine appendages. This caused the cessation of menstruation. The hemorrhage ceased and the myomata disappeared. In one case on which he had operated the menses recurred. He had not, he said, full notes of the case, but he had probably omitted to remove the tubes, which he now always made a point of doing. Mr. Tait said he considered his treatment of uterine myoma was as justifiable as any other surgical procedure, and the secondary

results were as good. It saved life and removed suffering as satisfactorily as did the removal of an ovarian tumor. Up to January, 1884, he had operated on fifty-eight cases. He had followed up the history of his cases, and out of fifty cases, there were forty-five of which he could give a complete and satisfactory account. As for the danger of the operation, he thought the mortality ought not to be one per cent.

Mr. Tait briefly referred to insanity as a complication. Two of his cases had been removed to asylums soon after being operated on. In one case the insanity manifested itself before the operation; in the other, acute melancholia came on as soon as the patient recovered from the anæsthetic. He alluded to other cases in which insanity had followed abdominal operations. He had himself seen it after removal of an ovarian cystoma, after hysterectomy, and even after a simple exploratory incision. It was not unknown after other surgical procedures, even those which were non-abdominal. Mr. Tait referred at some length in his paper to the opposition which he had excited and the obloquy which had been cast upon him. A paper read by him before the Royal Medical and Chirurgical Society had been thought unworthy of being printed in its "Transactions." He had, therefore, forwarded it to *The American Journal of the Medical Sciences*, where it had appeared. He maintained that the operation was perfectly justifiable, and had saved the lives of many patients who, but for it, would have died.

Dr. Gervis said that there were two justifiable plans of treatment for uterine myoma, viz., 1, to remove the uterine appendages; 2, to perform hysterectomy.

Dr. Playfair said Mr. Lawson Tait had, with his usual vehemence, set up an enemy merely to knock him down again. Gynecologists approved of Mr. Tait's procedure and appreciated his work. Mr. Tait only shared the difficulty which any man met with who brought out anything new. He had himself been accused of being a quack because he had introduced new methods of treatment. Mr. Tait, he said, had confused the opposition to the removal of the uterine appendages with that which had been expressed by many to their removal for pyosalpinx. Many had opposed their removal for the latter disease, though he himself had not. Dr. Playfair asked what were the indications for removing the appendages in uterine myoma? Why had Mr. Tait removed them in the patient who appeared healthy? He had himself known a case in which a woman had a large uterine myoma which reached to the ensiform cartilage. The woman was a monthly nurse, and had had it twenty-eight years. He had known her for twenty-five years. She suffered nothing from its presence, and the only objection to it was that everyone supposed her to be pregnant.

Dr. Imlach said that no surgeon was less fond of surgery than Dr. Keith. All the cases recorded by Dr. Keith were stated by that surgeon to have been known by him for years. He wished Dr. Keith had had the courage to operate sooner. He quite agreed with Mr. Tait as to the justifiability of the operation.

Dr. Edis also supported Mr. Tait. He said it had been denied that in these cases patients ever died from hemorrhage. *But they did;* he had seen it. Many doctors said we should wait for the menopause. He had known a case in which a patient had waited for the menopause until the mature age of fifty-six years, and there were then no signs of it. Had this patient been operated on sooner, ten years of enjoyment might have been added to her life. Referring to a specimen exhibited by Dr. Walter (of a uterine myoma removed by hysterectomy), he said we should never see such specimens. The patient should be operated on sooner, when the milder operation would suffice.

Mr. Tait, in reply, again referred to the opposition his views had met with. At the International Medical Congress held in London, August, 1881, he had been decried by London physicians. Dr. Priestley had accused him of wanting to operate for the sake of the fee for the operation. He might as well accuse London physicians of wishing not to operate for the sake of keeping the patient in hand, and going on taking fees for attendance, so that objection answered itself. As to pyosalpinx, he now regarded it as settled, and beyond the reach of argument. There were doubtful cases to be discussed. But in "reflex cases" he hedged himself about with so many conditions as almost to preclude him from operating. He could count on his fingers, almost on those of one hand, the cases in which he had operated without pelvic disease, and he could defend even these. As to whether his diagnosis was always correct he said that the fact of the patients coming to him was a proof that they had been dealt with before. Almost all the patients who came to him had been sent to him by practitioners, and came to him with a diagnosis already made. It has been objected that the operation produced sterility. But, he asked, how could a woman with such a tumor as that shown by Dr. Walter bring a child into the world? The tumor completely filled the pelvis. Another argument was that you unsexed a woman and deprived her from the enjoyment of sexual gratification. This had been shown to be incorrect. These two were merely windbag arguments, and only wanted pricking to make them collapse. Replying to Dr. Playfair, he said he operated in the case in question because of the exceedingly rapid rate of growth of the tumor.

Friday, July 31st—Third Day.

Dr. Gervis, in the Chair.

Dr. Berry Hart, of Edinburgh, read a paper on

the mechanism and management of the third stage of labor.

The oxyhydrogen light was used in illustration of this paper, the meeting being changed for the purpose to a room which could be darkened. Numerous micro-photographs were enlarged and thrown on the screen by means of the oxyhydrogen light and suitable lenses. Some microscopic sections were shown in the same way. Having shown the micro-photographs, etc., the shutters were opened and Dr. Hart then read his paper. The entire expulsion of the membranes was, he said, of great importance. We had obtained a good deal of knowledge through the attention which was now paid to abdominal palpation. After discussing at some length the structure of the uterine mucous membrane and of the decidua, Dr. Hart discussed the mode of expulsion of the placenta. It was, he said, expelled by uterine retraction and expression. There was little to shake Duncan's view that it was expelled edgeways in ordinary cases. But this mechanism was easily disturbed by adhesions and the fœtal surface made to present. The placenta and membranes were not expelled normally till twenty or thirty minutes after birth. The practical points to remember were that the placenta and membranes were not expelled for some time after birth, that they were expelled by contraction of the uterus, that expulsion took place edgeways, and that normally there was no entry of air. Dr. Hart recommended that, after the birth of the child, the mother should be placed in the dorsal position. The uterus might be grasped to maintain contraction, but Crédé's method of expulsion should not be applied too soon, as the placenta alone might thus be expelled, leaving the membranes behind. It should not be used in less than half an hour, and then only with the left hand. He approved of the employment of a douche containing corrosive sublimate (1 in 4,000).

Dr. Gervis said the dorsal position was important after the birth of the child. It was not a question of twenty minutes or thirty minutes, but we should not express the placenta at once by Crédé's method. The application of *pressure* to the uterus was, however, a good plan both before and after birth. He always instructed

the nurse to press on the fundus. Antiseptics tended to prevent hemorrhage.

Dr. Steel, Senior Vice-President, then took the Chair in place of Dr. Gervis, who was obliged to leave for London.

A paper by Dr. Braxton Hicks was then read by one of the secretaries in Dr. Hicks' absence. The paper was entitled, "On a Condition of the Inner Surface of the Uterus, after the Delivery of the Child, of Practical Importance." In his paper, Dr. Hicks stated that after delivery the inner surface of the uterus was, of course, considerably reduced in area by the contraction of the uterus. If the lining membrane were correspondingly reduced, the surface would be level; if not, it would be thrown into folds. He was not aware that the latter condition had ever been described. He had observed it and now drew attention to it. The importance of this state of the uterine mucous membrane was that it might be mistaken for a tumor or some other condition.

Dr. Freeland Barbour, of Edinburgh, then read a paper on "The Anatomy of the Placental Site with reference to the Third Stage of Labor," and exhibited a number of specimens illustrating his paper.

Mr. G. Padley then read a paper on "A Case of Acute Abscess of the Unimpregnated Ovary, with Recovery by Absorption."

Dr. D. A. Davies read a paper entitled "Short Notes of a Case of Chronic Inversion of the Uterus."

THE ACADEMY OF MEDICINE OF PARIS.

Stated Meeting, June 30, 1885.

M. Bergeron, President, in the Chair.

(Special Report for The Medical Record.)

The Academy being called to order, M. Luys presented

A PLASTER MODEL OF THE HUMAN BRAIN,

which had been designed by Dr. Descourtis. It was an exact reproduction of a natural brain, enlarged about four times, and measured 25½ inches in the antero-posterior diameter and 15½ inches in a vertical diameter. The speaker stated that this was the only model of the kind in France, the plaster brain made under the direction of Broca, and now in the museum of the Anthropological Society, not being an exact model of a natural brain, but rather a representation of what the ideal brain should be.

M. Gavoy presented a model of

AN IMPROVED STETHOSCOPE

furnished with a hollow chamber which served to intensify the natural sounds before they reached the ear.

Dr. Nicaise then read a paper upon

RICE-GRAIN HYGROMA OF THE THIGH.

He related three cases which had recently come under his observation, in which he had removed cysts, containing rice-like granules which microscopical observation showed to be tuberculous. Some rabbits inoculated with scrapings from the walls of the cysts, or with portions of the rice-grain bodies, presented evidences of tubercular infection, though they had not yet been subjected to a conclusive examination. In one of the cases the inflammatory tubercular process had given rise to the exudation of a fibrinous mass, weighing nearly twelve and a half ounces, without serum or pus. This fact would seem to show that there was a special form of

TUBERCULAR INFLAMMATION OF SEROUS MEMBRANE,

not leading to cellular proliferation or transudation of white corpuscles, but to the formation of a large quantity of fibrinous material. The speaker also reported a case of fungous arthritis of the knee, in which there was, at the same time, a soft semi-fluctuating swelling in the immediate neighborhood of the articulation. This was opened, and M. Nicaise was surprised to find, instead of suppurating fungous proliferations, a reddish, translucent, dry, fibrinous mass, completely filling a cavity whose wall was infiltrated with tubercular growths. The author asked whether these forms of hygroma and synovitis, in which the rice grain bodies were found, were always tubercular in their nature. He thought it was a question which could not be answered without further study, and the knowledge derived from more extended observation.

M. Constantin Paul then made a report upon

AN ELASTIC RESPIRATOR,

devised by Dr. Basil Féris for use in the treatment of pulmonary emphysema. The apparatus was something like an elastic truss for double inguinal hernia, but with the pads pressing in a reversed direction. It was applied in such a way that the pads rested in the second intercostal spaces at the level of the union of the ribs with the costal cartilages. Dr. Féris had used the respirator in nearly thirty cases of emphysema, and in only two did it fail to give more or less relief. The reporter regarded the apparatus very favorably, and thought it very useful in remedying the want of tone in the respiratory muscles. The muscles of inspiration were not fatigued by this compression if it were only equivalent to, and not greater than, the normal tonicity of the expiratory muscles. The respirator was useful in habitual dyspnœa, even of considerable intensity, and failed only in cases in which the difficulty in breathing was excessive, as in certain attacks of spasmodic asthma.

The speaker read a second report upon a memoir entitled

BILIARY LITHIASIS AND ITS SYMPTOMS,

by Dr. Merle. The author maintained that it was frequently impossible to conclude as to the existence of biliary lithiasis from the general symptoms, and that certainty in diagnosis could be obtained only by the discovery of the biliary concretions in the fæces. Individuals suffering from this condition, he asserted, were subject to attacks of intense colic followed by diarrhœa, and if the stools were examined they would be found to become more and more liquid and to contain a constantly increasing amount of biliary gravel. The latter might be more readily detected if warm water were added to the stool, as the fecal matters would rise to the surface, while the gravel would sink to the bottom and could be found by decanting the upper layer of fluid. The author had based his conclusions upon a very small number of cases, but the reporter regarded them as worthy of attention, and advised that Dr. Merle pursue his investigations further, with a view of strengthening his previous observations.

Finally, M. Paul presented to the Society, in the name of the author, the second edition of

LESSONS ON MINERAL WATERS AND HYDROTHERAPEUTICS,

by M. Durand-Fardel.

The Academy then went into executive session.

The Laicization of the Hôpital Cochin.—The Paris authorities recently voted to laicize the Hôpital Cochin, one of the few institutions of the kind still under the charge of the sisters. But they have met with an obstacle which may bar their further progress. In examining the records it was ascertained that according to the terms of endowment there was a stipulation that the hospital should always be under the care of the sisters of charity, under penalty of forfeiture of the land and money to the original heirs. There are said to be many of the latter in Paris who are only waiting for the execution of the decree to bring suit for the property.

Correspondence.

OUR CARDIFF LETTER.

(From our Special Correspondent.)

(Continued from p. 223.)

CARDIFF, SOUTH WALES, August 2, 1885.

THE other general meetings were fairly well attended. I need not refer to the general addresses, as your readers will have had the opportunity of forming their own judgment on them long before you receive this—in fact, before it is posted here. Suffice it to say that they were numerously attended and well received. The work of the sections is described to your readers in separate reports. I subjoin a few notes about the museum.

The annual museum has of late years been quite a feature at the annual gathering. The rule is that the objects shown must be genuine novelties. This rule is not very rigidly interpreted, the consequence being that many of the exhibits are by no means novel. As at larger and more pretentious exhibitions, there is also an unmistakable commercial air about some of the stalls. The exhibitors, in fact, take a stall and exhibit for the sake of the advertisement. It pays them. The commercial aspect is sometimes a little too much to the front, though I think in this respect Cardiff has been better than some former meetings. Still, in spite of these slight drawbacks, the museum is always worth a visit. I will briefly mention some of the exhibits which struck me as noteworthy.

Messrs. R. & J. Beck showed some very cheap microscopes, nickel-plated, on a solid stand, and with a one-inch and one-fourth inch objective, for a very moderate sum. For a little extra, a one-sixth inch objective was included. The same firm showed several specimens of micro-organisms under various powers, viz., bacilli anthracis, spirillum of relapsing fever, bacilli tuberculosis, and comma bacilli. A new microtome was also shown, but as the cost is fifteen guineas, it is not likely to be purchased except for special work.

Mr. Immisch exhibited a very neat metallic thermometer, resembling a watch very much in appearance, having a transparent face, and a hand which indicated the temperature. It was not self-registering, but as it took thirty seconds for the index to return to the starting-point, the reading could easily be taken. A very handy surface thermometer was shown by Messrs. Mayer & Meltzer.

A convenient ether-freezing microtome was shown by Dr. R. A. Hayes, of Dublin.

Mr. Jahncke exhibited his very convenient nickel-plated pocket urine-test case, also a pocket hypodermic case, and patent boxes of similar construction for carrying bottles.

Messrs. Millikin & Down exhibited, among many other instruments, Mr. Golding-Bird's tracheal dilator, made on the principle of the nasal speculum. This was, strictly speaking, not a novelty, having been introduced some few years since, but I think it was new to many present.

Messrs. Essinger exhibited Hartmann's patent wood wool, wood wool wadding, and hygienic wood wool diapers.

Messrs. Krohne & Sesemann had on view Kabiersky's powder-blower, for the application of powdered medicaments for the antiseptic treatment of wounds, diseases of the throat, nose, ear, eye, etc.

Several anæsthetic appliances designed by Dr. R. T. Freeman were shown by Mr. J. F. Blennerhasset, of London.

A more complete series of Dr. Oliver's urinary test papers was shown, also Dr. Pavy's test-pellets for sugar in the urine.

Models were on view of Morrell's Patent Combined House-ashes and Earth-closet System.

Withington's Patent Sewer-gas Excluder was a rather curious piece of mechanism. It consisted of a solid plug so arranged as to act as an obturator in the soil-pipe when the closet was not in use. When the closet was flushed with water the plug moved to one side. The exhibitor seemed to think it was quite as good as, or even better than, a good ventilating pipe in excluding sewer-air.

I noticed an exhibit of the Buffalo Natural Lithia Springs. Messrs. Burroughs, Wellcome & Co. had a large stall of pharmaceutical exhibits, as also had Messrs. Allen, Hanburys & Co.

A large and interesting stall was that devoted to Jaeger's patent clothing. Dr. Jaeger appears to be an enthusiast. He has persuaded himself that it is his mission to press on the public the desirability of clothing themselves from head to foot in products derived solely from the animal kingdom. Vegetable fabrics are to be discarded. A large box of camel-hair was presented to every visitor to the stall who would take it, and also a well-bound volume, of nearly two hundred pages, describing the system and enforcing its value and importance.

A separate room was devoted to anatomical and pathological preparations. Among these were some sagittal mesian sections of the female pelvis (frozen), sagittal lateral sections of female pelvis, and axial coronal sections of female pelvis, showing the relations of the ureters to the vagina and cervix uteri. These were exhibited by Dr. D. Berry Hart, of Edinburgh, one of the Secretaries of the Obstetrical Section.

I must now bring this letter to a close. You have already learned that the 1886 meeting is to be held at Brighton. Dr. Withers Moore is the president-elect. It is rather early to prophesy as to the next meeting, but I think it is likely to be more largely attended than any meeting of recent years. Brighton is of easy access from all parts of the south coast, and is but little more than an hour's run by rail from London, where alone we have over nine hundred members in the Metropolitan Counties Branch of the Association.

THE CARDIFF MEETING—ANOTHER ACCOUNT.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: All those who attended the Cardiff meeting must admit that it was one of the most pleasant and also one of the most successful of those held within the last few years. Such at least is the general impression amongst those who have recently returned to town from the meeting in South Wales. Wales is noted for its hospitality, and on this occasion the festivities provided by the liberality of the local worthies did much to enliven the scientific proceedings. Not that a certain number of entertainments is not the custom at the annual meetings. A certain amount of amusement is always blended with the scientific repast provided, and of late years this has tended to preponderate. So much so, indeed, that some wicked people whisper that many members attend the annual meeting mainly for the sake of the fêtes. However this may be, I think those who attended the President's reception in the Park Hall on the Wednesday evening, and danced till two in the morning, were not very likely to arise early and put the finishing touches to the papers they were to read. I much fear, also, that several members of the Council were late at the Council meeting, held at half-past nine on the following morning. Strolling along the banks of the canal by the light of many-colored Chinese lanterns, and listening to the distant strains of the Hungarian band, or turning in the giddy mazes of the waltz, was rather calculated to take the edge off the zest for scientific inquiry which the members of the British Medical Association are supposed to possess.

Some scientific instruments and a few microscopic objects were shown up-stairs, but even the latter were of more popular than medical interest. This was doubtless

in deference to the presence of ladies, for the fair sex are admitted to the entertainment. They are, too, not confined to the medical element, but invitations were freely scattered among all the local magnates. Both on Wednesday and at the Mayor's reception on Friday, the ballroom proved the chief centre of attraction. On the latter occasion the revellers did not depart till daybreak. About fifteen hundred were present each time.

The dinner passed off without any very striking incident, except that one gentleman fell off his chair by sitting down on it too near the edge. This raised a laugh at his expense in his immediate neighborhood. Some remark was caused by the President giving the signal for "lighting up" by making the customary remark that the duty was taken off tobacco immediately after the Queen's health had been drunk, instead of, as is generally done at public dinners, waiting till the Prince of Wales' had also been drunk. Mr. Wheelhouse, in proposing the Army, Navy, and Auxiliary Forces, did not at first observe that a naval officer was present to respond for the Navy, but he afterward repaired the omission. The High Sheriff of Glamorganshire, Colonel Hill, caused immense laughter by stating that he had, when he first learnt that the Association was to meet at Cardiff, turned to the "Encyclopædia Britannica" to learn something of the origin of surgery. He had there, he said, found it traced back to the Egyptians, and the origin of bleeding credited to the hippopotamus. That animal, it was said, when depressed, was accustomed to bleed itself by running its leg against a stump. Professor Lucae, of Berlin, was amongst the visitors present, and, in proposing "The Guests," Dr. Wilks coupled his name with that of Dr. Duncan Bulkley, of New York.

Lest your readers should imagine that all play and no work was the order of the week, I will now refer to some of the work done. Two important discussions took place in the Section of Medicine, viz., on "Acute Rheumatism" and "Glycosuria," respectively. Dr. Bristowe introduced the former, and surprised those who only knew him as the author of a very learned but rather heavy text-book, by the ease with which he spoke and the point and interest he imparted to his address. Dr. Bristowe, indeed, made an excellent speech. Dr. Pavy introduced the discussion on "Glycosuria," but the length of his address was rather wearisome. Readers of papers are limited to fifteen minutes, but this rule does not apply to those who introduce discussions. Dr. Pavy much exceeded it, and consequently left but little time for subsequent speakers. Dr. Pavy was again to the front on the following morning, when he occupied nearly an hour in reading his paper on "Cyclic Albuminuria." He brought forward a number of interesting points, but he has not the advantage of being a good speaker, and it was scarcely fair to exceed the time allowed for papers to so great an extent as he did. He actually occupied a good deal of time in reading various letters from patients and their doctors. This involved a good deal of repetition. Dr. Pavy is one of our ablest London physicians, and what he says is always to be listened to with respect, but I cannot help thinking that he might have considerably shortened his paper with advantage. Much of it was so elementary that it was only suitable for a clinical lecture. Dr. Wilks, the President of the Section, was placed in rather an awkward position. Being Dr. Pavy's colleague at Guy's Hospital, he, no doubt, scarcely liked to "shut him up" in fifteen minutes.

What I have said about the set discussions, applies equally to other Sections. Thus in the Section of Pharmacology and Therapeutics, the last morning (two hours) was allotted for the discussion on "Anæsthesia." A paper on another subject was also put down to be read. Dr. Dudley Buxton, of University College Hospital, introduced the discussion, and took an hour and a quarter to do so. As he read every word, and has not a particularly good delivery—rather the reverse—it is not surprising that many of "the practical men," whose opinions he said he wished to elicit, took up their hats and departed after patiently listening for some time. Dr. Buxton occupied another quarter of an hour in his reply, thus making an hour and a half altogether. His paper was not by any means devoid of interest, but it would have been much better received had it been shorter. The discussion was very freely joined in by those present, though the time was much abridged by the lengthy introduction. I am disposed to think that there is a good deal of reason in what I have heard stated, anent the Cardiff meeting, viz., that a man who cannot say his say in half an hour had better write his paper out and send it to the *Journal*, and not pretend to join in a discussion, at any rate where the time is so limited. On the present occasion, a good deal of time was occupied by the reading (by the Secretary) of a communication from Professor Cheyne, of Edinburgh. Professor Cheyne had promised to take part in the discussion, but being unable, printed his contribution in pamphlet form and sent a number of copies for distribution. As each gentleman present had thus before him a printed copy, it was surely unnecessary to occupy the time by reading it aloud, also especially as a larger portion of it had appeared in a medical journal about a year ago. Professor Fraser, however, ruled that it should be read and read it was.

The Surgical Section was scarcely as successful as last year. The two discussions went off well. Those who were anxious to hear Mr. Lawson Tait's views on Intestinal Obstruction were disappointed, as that gentleman did not turn up at the appointed time, being presumably engaged in the Obstetrical Section. Putting aside the two special discussions, I scarcely think the papers read were (taken as a whole) of equal interest to those of last year.

The Obstetric Section was very well attended. An animated discussion took place on "Antiseptic Midwifery." Dr. Clifford Allbutt, too, received a good mauling. Perhaps it was as well he was not present in person to respond, or the discussion might have become still more personal than it did. Dr. Berry Hart made rather a good show by exhibiting about twenty or thirty micro-photographs by means of the oxy-hydrogen light. The photographs were enlarged and thrown on a screen, the room being darkened for the purpose. The display would have been more instructive had Dr. Berry Hart read his paper first and then showed the specimens. As it was, some of them were rather difficult to understand. Each one appeared for only a few seconds and was then quickly succeeded by another, Dr. Hart adding a few words of explanation. He afterward read his paper, which was rather difficult to follow, as he read very quickly, and his enunciation was not very distinct.

Otology was apparently not very popular, as I understand all the otological business was got through within one afternoon. Ophthalmology attracted more votaries, the presence of some distinguished foreign ophthalmic surgeons proving an attraction.

I need not pursue in detail the work of the Sections, as you already have special reports of them.

Medical practice in Cardiff and South Wales generally is, I am informed, highly remunerative. This is fortunate, as the expenses of the late meeting have been heavy, and a considerable proportion of them will fall on the local Branches of the Association. I was told that the Conversazione given by the President and Reception Committee would alone cost five hundred pounds. In the colliery districts of Wales, I understand, many of the colliery surgeons make very large incomes. It is, it appears, a sort of rule for all the colliers to pay the colliery surgeon so much weekly in proportion to their earnings. Three pence in the pound was mentioned as a usual sum. Where wages are good and many men employed, it will readily be understood that this may pay very well. One surgeon frequently has several collieries, and employs many assistants. I heard of one who employed twenty,

and was surgeon to collieries in two different valleys. Many colliery surgeons are said to make thousands of pounds a year, and I even heard a story of one who lived quite in the country among the hills, and made fifteen thousand pounds a year, though the latter sum sounds rather apocryphal.

I will conclude by relating a story I heard while in Wales: A certain doctor in a certain district was noted as being a very absent-minded man. He was sent for one day to visit the wife of a banker. On arriving, he walked into the drawing-room, took no notice of the lady, but walked straight to the mantelpiece, and, resting his elbow on it, leaned his head on his hand and sighed deeply two or three times. He then went away without speaking to his patient. He had, in fact, not thought about her, being engrossed in thought about another one. She, however, thought otherwise. Her husband came in presently, and she asked him what the doctor had said. She knew, she said, that the doctor thought she would die, only he did not like to say so. In vain the husband protested that he had not even seen the doctor. The latter was finally recalled, and asked for his opinion. He then said he could not say what illness the lady was going to have, but she was to go to bed and stay there until he called again. He did not call again for six months. This was gravely related to me as a *bona fide* occurrence. I am not prepared to vouch for its accuracy, but the narrator told me it was perfectly true and well known. Absent-mindedness is, of course, not found only in Wales.

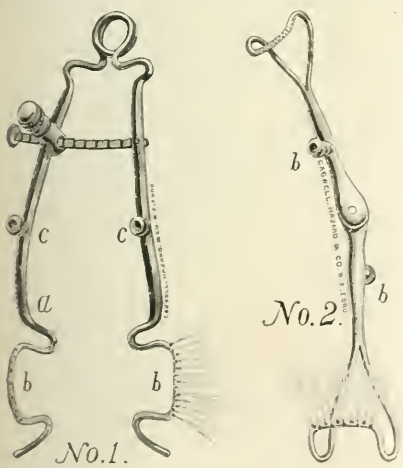
New Instruments.

A NEW INSTRUMENT FOR WASHING THE UPPER CUL-DE-SAC OF THE CONJUNCTIVA.

By JOSEPH A. ANDREWS, M.D.,

OPHTHALMIC SURGEON TO CHARITY HOSPITAL, NEW YORK, ETC.

In purulent conjunctivitis the first and most important indication is to wash away the infective material as early and as thoroughly as possible.



A thorough cleansing of the upper cul-de-sac is not possible by the ordinary means. The instrument pictured above is designed to secure the fulfilment of this important indication. Figure 1 is an eye-speculum, the arms, *a*, of which are hollow, and the claw, *b*, is deeper than in the ordinary eye-speculum. The claw has a number of perforations through which the water is injected into the upper cul-de-sac. At *c* a fine rubber tube is attached and connected with a fountain syringe.

The instrument requires to be introduced between the eyelids with great gentleness, and care should be taken to avoid injuring the cornea with the instrument. The eyelids should then be gently lifted from the eyeball and the spray of fluid allowed to play upon the upper cul-de-sac.

Figure 2 represents a folding lid-elevator (large and small size) designed for the same purpose as the eye-speculum. The arm is also hollow, and the perforations are in the claw. The tube of the fountain syringe is attached at *b*.

An ordinary syringe has been used to wash the eye in purulent conjunctivitis, but its use should be seriously deprecated, because it never fulfils its purpose; moreover, in driving the piston-rod home, the nozzle of the instrument being between the eyelids, the eyeball is very likely to be injured, and the fluid is invariably injected all over the patient's face, and the operator does not escape it.

These instruments are manufactured by Mr. W. F. Ford, of Messrs. Caswell, Hazard & Co., of New York.

A Visit to the Clinic of Professor Gussenbauer in Prague.—Professor Gussenbauer is the presumptive successor of Professor Billroth, whose assistant he has been for many years; he is a very able and remarkable surgeon, and one of the best teachers of the age. He is about forty years of age and occupies the chair of surgery in this most ancient and celebrated University of Prague. For five years he filled the same chair in the University of Liege, and taught in French. The Government wanted to confer honorific titles and medals on him, which he declined, and asked instead to create places for surgical pupils (operations Zoeglinge) at the clinic of Prague. The surgical amphitheatre is a magnificent room, quite new and of huge proportions, admirably adapted both for lectures and operations. It is lighted from a glass ceiling and lateral windows. First the outdoor patients are attended to, then the house patients are brought in on stretchers. Two or three medical students are called up to make a diagnosis. The history of the case is then given and the proposed plan of operation is stated and explained. A man seventy years of age is brought in, with a cavernous angioma of the left ischio-rectal fossa. He only uses a bistoury; a dissection of insurmountable difficulty for a less skilful operator, lasts not less than an hour. The tumor of the size of two fists is formed of two distinct parts, the inferior half has the character of an angioma, the upper half that of a sarcoma. The ischio-rectal fossa is tamponed with iodoform gauze. Then came a resection of the elbow, for fungous arthritis; then a case of ablation of intramuscular lipoma of the neck; then an amputation of a leg. Esmarch bandage is applied. One of the "operations Zoeglinge" performs the operation under the eyes of the professor. He has to detach and turn back the periosteum before applying the saw, etc., etc. He averages five operations a day before his class, from 10 A. M. to 12 M. Antiseptic precautions are minutely carried out. For many years he used phenic acid, of late, the corrosive sublimate, 1 to 500, is his remedy, he plunges his hands in repeatedly during the operation; ligatures are soaked in the corrosive sublimate solution, but instruments in that of phenic acid. He is ably assisted by his internes and by the "operations Zoeglinge." Traumatic fever is unknown at his clinic, doubtless due to the strict antisepsis.—*Prog. Med., St. Louis Journal of Medicine and Surgery.*

The Modest View of Specialism.—When the worst has been said against specialism, it still remains as a system of work which, if narrow and comparatively humble in its aim, is practically more successful in attaining it than broader and more philosophical methods. The final test of every institution as of every individual in these days is the record of actual achievement which it has to show. Judged by the standard of results, whether in the shape of additions to the store of scientific truths or to the armory of weapons against disease, specialism has nothing to fear. Even its enemies must admit that it is to it that the vast strides which the art of healing has taken in late years are mainly due, and there can be no doubt that medicine can only continue to advance by a process of specialization becoming more and more minute. In the eyes of *idéquologues* whose breadth of view rather impairs the keenness of their vision of things close at hand, the specialist no doubt may appear a somewhat unheroic figure beside his larger-minded brethren. Practical men, however, consider less the intrinsic nobility of the work than the efficiency with which it is done.—*Dr. Morell Mackenzie.*

The Bees and Apollo: a Medico Pharmaceutical Fable.—Once upon a time the busy bees were gathering honey from a flowery field on famed Hymettus. Suddenly one bee was heard to buzz much more loudly than the rest of his companions, who, upon listening, heard that he had found a new process for extracting a superior honey of remarkable medical properties. He had also, at the same time, invented a very ingenious way by which he could with comparative ease make his buzz sound four times as loud as that of the ordinary bee. By means of these inventions, he soon disposed of large quantities of honey at a high price. But one day, Apollo, who was experienced in the matter of honey and its medical properties, came that way, seeking some good sample for the use of his friend Diana, who was a little ill. He looked at the new preparation, which was put up in soft capsules and called "honeyine," and at another kind which was put up in chocolate tablets and called "honey-idea." He also listened to the new buzz. "I think," he said finally, "that the buzz is much more wonderful and effective than the honey; I will take it to Diana, who is fond of buzzing." Some days later, Æsop, on hearing this story, remarked that the moral which he would add was, that the art of advertising a new medicinal preparation is of more importance than the art of making it.—*Boston Medical and Surgical Journal.*

Bullet-wounds of the Heart.—Dr. T. H. Brannan, of Canal Dover, O., referring to the fact that "the experience of experts with shot-gun wounds of the heart is limited," reports a case in point. About 4 A.M. June 17th, a miner was shot. "He turned immediately around, and walked seventy-seven paces in the direction of his house, climbed over a board fence, three boards high (the fourth and top board being gone), proceeded two hundred paces farther to the front gate of his residence and there fell. From here he was carried into the house, propped up in bed, and at the end of thirty minutes passed into a convulsive tremor of short duration, at the end of which he was dead. He was rational to the last, and conversed up to the moment of his death. At the autopsy five hours later a No. 2 shot was taken from the calf of his right leg; one from the left wrist; while the third and fatal one entered the chest in the third intercostal space of the left side, one inch above, and two and one-half inches inward, from and on a line drawn from the left to the right nipple. From this point the shot passed backward and to the right, passing through in its course and in their order both walls of the pericardium, the base of the pulmonary artery, the left auricle, the inner border of the lung, and impinging upon the right side of the body of the fourth dorsal vertebra, at which point it glanced off and was lost in the body. The pericardium was found distended with coagulated blood, and the pleural cavity contained a smaller quantity.

Pityriasis Versicolor.—This discoloration of the skin is occasioned by the presence in the epidermal layers of a parasite known as the *mycrosporon furfur*, and is often cured by the external use of sulphur in the form of daily baths and frictions with the ointment. An ointment consisting of 20 drops of nitric acid in 1½ ounce of lard is also said to be efficacious. Another remedy which has been used successfully is a lotion of corrosive sublimate of the strength of 1 part to 1,000.

Extract of Male Fern.—Krämer recommends as possessing very active properties an extract prepared in the following manner. The rhizome is gathered in May and October, is scraped and divided into small fragments and exhausted, while still fresh, in ether containing a very small proportion of alcohol. The ethereal tincture thus prepared is kept in closely stoppered flasks in a cool place. When wanted for use a sufficient quantity is evaporated to the proper consistence, and the extract is obtained.

The Raillière Springs at Cauterets.—A report has been going the rounds of the French press to the effect that the Raillière establishment in Cauterets had been nearly destroyed by a storm, and that the composition of its spring had been materially modified. This report is now contradicted by Dr. Bouyer, the medical inspector of Cauterets, who affirms that it is a malicious fabrication originating in a rival establishment, jealous of the increasing popularity of this thermal station.

The Medical Record

COUGH.

By J. MILNER FOTHERGILL, M.D. EDIN., HON. M.D. RUSH MED. COLL., ILL.,

PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST (VICTORIA PARK).

IN this day of careful physical examination of the thorax some other matters have almost dropped out of sight. The old physician who recently declined the loan of a stethoscope by a young clinical assistant for the diagnosis of pneumonia, saying, "Thank you, young man; but I think I can detect pneumonia without a stethoscope!" could no doubt have taught that youth much that would be useful to him. A stethoscope is a capital instrument in the hands of a man who knows its use; but it has undoubtedly drawn attention away from what may be termed rational consideration of the chest, and a judicial handling of what the patient has to tell, which often furnishes a clew to the treatment; a matter on which sometimes the stethoscope is silent. It is not that physical examination is not a most valuable means of acquiring certain information; but that this other information is apt to be overlooked or underestimated; and thus a good proportion betwixt the two means of examination is lacking.

A cough is a forced expiration to eject some offending material from the air-tubes, just as a sneeze clears the nares. But suppose the offending or irritant matter cannot be ejected, what then is the value of the cough? Nothing whatever. There is, then, much useless cough, as well as useful cough. Other matters than something in the air-tubes may set up a cough. Thus we find cough equally present when there is some phlegm in the air-tubes; when there is a mass of tubercle undergoing softening; and in the pulmonary congestion of a mitral lesion. A crumb in the larynx will provoke violent cough; and so will other laryngeal irritation. All know the brazen trumpet-like cough of aneurism of the aortic arch pressing upon the recurrent laryngeal nerve, a cough closely simulated in character at times by a neurosal cough. This last was so marked in two girls that their cough told when they were on the hospital premises. It is needless to say their departure was always expedited. Then, cough in the form of "hawking" is exceedingly common in pharyngeal disturbance.

There is, too, cough unconnected with the air-passages and the respiratory organs. There is the well-known cough of pregnancy, the "nine months' cough." There is ear-cough, said to be connected with the tympanic branch of the glosso pharyngeal nerves, which is set up by irritation in the ear. There is the cough of gastric irritation, common with alcoholic indulgence. In one case, at least, known to me, diarrhœa always set up cough. Cough of the "hemming" character, often misinterpreted as the short cough of early phthisis, is found commonly in girls at or after puberty, linked with ovarian or spinal irritation. It is clear, then, that cough has various causal associations.

The importance of reflex cough need not be considered here; nor yet the means by which it may be relieved. In all reflex actions the bromides suggest themselves at once. If the exciting cause can be dealt with, then the resultant cough is relieved.

It is rather the intention here to consider cough from its clinical and therapeutic point of view, and to see what indications it furnishes us for treatment. For instance, in "heart cough," *i.e.*, where the cough—a hard, dry cough—is set up by congestion of the pulmonic or lesser circulation by some dam or block at the mitral ostium, sedatives are most undesirable.

Such cough is most commonly found in a young girl with a mitral lesion. One such case I well remember when the resident medical officer of the Leeds Public Dispensary. The girl, a child of twelve, had mitral regurgitation—an injury inflicted upon her previous to her coming under my notice. Digitalis and iron improved the general condition, and with it the amount of cough; but still the child, a bright neurosal creature, coughed considerably. She ceased to attend, but some weeks later her mother came and made a frank confession to this effect: "Doctor, I thought the girl ought to have some cough medicine, and when I asked you for it, you always refused to give her any. One day I came when I knew you would be out, and got one of your assistants to grant me some cough stuff. It acted like a charm; but she soon fell off and lost her appetite, and could not get about; and now there is dropsy in her ankles. She is so bad, I want you to do what you can for her." Appropriate treatment soon restored the child to her ordinary condition; but her mother did not hanker after cough medicine after this experience. This case illustrates vividly the disastrous effects of allaying the cough when due to pulmonary congestion. For a little time it gave relief, but the after condition was worse than the first. So much for the indication afforded by cough under one set of circumstances, the case just mentioned by no means standing alone.

The consideration of "useful" and "useless" cough may now engage our attention. It is a matter involving the gravest thought, and well deserves our best consideration. We will take cough in bronchial cases first. There is in the early stages of acute bronchitis much useless cough set up by the dry mucous membrane, and the means for its relief have been set forth in a preceding article ("Bronchitis, Acute and Chronic"). Then it was said there existed no particular objection to opium, which gives great relief. But in such case the sedative is combined with other agents of a relaxant character, as tartar emetic or aconite. As soon as free secretion comes the cough changes its character. It is no longer the dry, harsh, shaking cough of ineffectual effort, raising nothing, but becomes the less painful, truly expulsive cough of successful effort. Now, what we are required to do is to give stimulating expectorants, and so help and improve the character of the expulsive cough. There is usually at this point no indication for opium, and none is required unless it be a little at bedtime in certain cases.

It is rather in chronic bronchitis with little expectoration and much bronchial irritation that the question of decision taxes our best mental energies. In some cases the rest at night is broken by irritant cough, and then the question arises of the lesser of two evils. If the opium arrest the secretion, and so render it tougher and more difficult to get up; if the opium brings lethargy to the liver, impairing the appetite, and locking up the bowels, still it gives the patient rest. Consequently it may become necessary to administer it. But it should be given with benzoic acid in compound squill pill, and a little podophyllin or watery extract of aloes to coun-

teract its undesirable effects in the alimentary canal. And by such combination no doubt the maximum of good with the minimum of bad effect can be secured. Numbers of chronic bronchitics under my father's professional care took such a pill every night for years without apparent injury, while it added greatly to their comfort. (I refer to my father's experience in these cases because I served under him and saw his practice, my own experience of general practice being but short.) But granting all this, the less opium in disease of the respiratory organs the better—as a broad rule. Sometimes some chloral, or bromide of ammonium with tincture of hyoscyamus, may seem indicated rather than opium, or even camphor may be the best agent to employ in certain cases. But, in a general way, opium (in such pill-combination as has just been suggested), with some alcohol at bedtime as a "night-cap," *i.e.*, whiskey or brandy and hot water, taken on getting into bed, is the best practice with chronic bronchitics. One great matter there is in such cases, never to be lost sight of by the patient, and that is to avoid passing from a warm sitting-room to a cold bedroom; the bedroom should also be warm. Another is to have the bed warmed by the old-fashioned warming-pan, or, perhaps better still, by a hot-water bottle, which can be pushed down to the foot of the bed (so as to keep the feet warm) when the patient gets into bed. This matter of an equable temperature is very important, and many bronchitics toast themselves well before going upstairs to a cold, unwarmed bedroom, where they cast off their day clothes, don a cold night-shirt or gown, as the case may be, then kneel down and say their prayers, and get into a cold bed. It is needless to say that no medicinal course can be successful in a case where this goes on.

Important as the matter of cough and its indications for treatment are in chronic bronchitis, the matter of cough in chronic pulmonary phthisis is even still more important. There is the cough in the night breaking the sleep, and there is the cough in the day shaking the sufferer; both objectionable and undesirable, and requiring to be dealt with. The circumstances under which cough is developed in pulmonary phthisis vary. Sometimes mere apex consolidation is accompanied by cough. Where there is bronchial implication and localized bronchitis in the affected area this can readily be understood; but at times there is cough without the moist râles indicative of this condition. We are compelled here to suppose some irritation of the pulmonary fibres of the vagus, which is transmitted to the respiratory centre, leading to a discharge producing the modified inspiration and expiration familiar to us as "cough." Belladonna is said to exercise a decided influence over these fibres, and so is indicated in such condition. (By this property belladonna, or atropine, is a desirable addition to an opiate for a night-pill.)

It has also been claimed for gelsemium sempervirens that it is useful in such cough by its action upon the nervous mechanism of the respiration. Bromide of ammonium suggests itself at once for the relief of such cough, from the known utility of the bromides in all reflex trouble.

One curious point there is about cough in its relations to static pulmonary consolidation, and that is this: Whenever a person possessed of a patch of consolidated lung has also the liver upset, then the irritation in the said patch with resultant cough is marked. No cough medicines nor antispasmodics do any good; but agents which act upon the liver, as a blue-pill at bedtime (or other mercurial), and a dose of sulphate of soda next morning, produce a distinct and unmistakable effect in lessening the cough. Consequently, when a patient complains of troublesome cough and an area of consolidated lung is found, it is often well to inspect the tongue and inquire into those subjective sensations experienced when a person is bilious or "liverish." From its known effect upon the liver, opium not only gives no relief, but positively aggravates the condition.

When a tubercular mass, or a portion of the consolidated area commences to soften—probably by the proliferating cells being so crowded on each other that they die; possibly by the appearance of bacilli on the scene—then we can readily understand the oncome of cough, and often severe cough. The dead mass is an irritant—like the thorn of Van Helmont—as a process of ulceration cuts it off from the surrounding lung-tissue; and during the time the process is going on there is distinct local irritation setting up cough. There is, too, hectic fever, with nocturnal pyrexia and night-sweats. In this condition it may become necessary to add some opium or morphia to the mixture of quinine and phosphoric acid so much in vogue for its relief; and whether any sedative must be added or not; and if so, what quantity is a matter to be decided by the merits of each particular case. That some morphia is unavoidable to procure sleep in such condition goes without question; but it must be guarded by the additions suggested in the article on "Pulmonary Phthisis." Such a condition is like a specific fever, or a storm at sea, in that it comes to an end sooner or later, and if the organism can be kept going, or the ship afloat till the end comes, all is well. Of course if there be but one softening patch the irritation set up is smaller than when there are several such morbid areas. In the latter case, opium in the day may be unavoidable; and its drawbacks must be met and got rid of, or neutralized, by such wit and skill as the medical attendant can command, either in himself or in some consultant of more experience or deeper thought. Above all things, keep up the powers by such food as the patient can take. The fever usually brings with it thirst. Then let the patient have cold beef-tea, with baked flour in it; malt extract, with effervescing water; milk, with a mineral water or whey; or milk diluted with water, and some Mellin's food added; and good home-made lemonade, with a fair amount of acid and sugar or malt extract in it. Rice-water, or barley-water, or tamarind-water may be relished. Grapes and the juice of fruit are excellent. Alcohol may, too, be indicated. Sometimes it is neck or nothing. The patient must be heavily dosed with opium to allay the paroxysms of cough; aye, and there is something more than cough, viz., the danger of hemorrhage from a ruptured blood-vessel in the softening area, brought about by the violent effort of cough. The poor patient is like a soldier with the bullets flying over his head; if he escapes one, another hits him. The patient is passing through a period of acute perils; perhaps rather, he is like a canoe shooting rapids studded with rocks; much, very much depends upon the boatman's skill and experience; something upon luck—and the patient's luck is the luck of a good constitution! If the softening areas be numerous or extensive, then the prospects of escape is small, and the skill of the steerer will be gravely taxed. In spite of everything that skill and assiduous attention can do or accomplish, the case may go on from bad to worse unto the inevitable end.

But, in my own experience of phthisis, cough has not been so very prominent a matter as to require treatment in the day, except in a few instances. It is not common for the consumptive to be shaken by racking cough requiring opium in the day. And on inquiring of an experienced sister at the hospital, who has watched the practice of many physicians, including the late Dr. Peacock, she informs me that my personal experience is in harmony with that of other physicians at Victoria Park Hospital. It is at night that cough is prevalent; and the use of opium, in combination with other agents, to procure a good night for the phthisical is a matter upon which there is general agreement.

When there is one or more cavities present, the use of opium is not affected by the fact. Indeed, a cavity is a matter of little moment, either one way or the other, therapeutically. Of course, the patient is no better for having a cavity; but the question is, Is he any worse? Patients with cavities die, certainly; and patients with

cavities leave the hospital very greatly improved by their stay. As to the question of cough and its treatment, a cavity counts for nothing; the cough certainly may be connected with its contents, or perhaps the condition of its wall. But the fact of the patient being in the third stage of phthisis (following the classification of Pollock in his "Elements of Diagnosis in Phthisis") does not affect the treatment.

Finally, in dealing with cough, the physician must observe and reason upon the cause of the cough, what it accomplishes, and how it affects the patient, before proceeding to deal with it. Some cough is useless, because ineffective, and needs some stimulating expectorant to render it efficacious—a very common affair; some cough is useless from every point of view, and so requires a sedative; and here the physician must decide in each case which is the lesser of two evils—the cough, or the sedative.

London, W.

TWO CASES OF EPILEPSY WITH RARE COMPLICATIONS — GRAND AND PETIT MAL WITH SHORT PERIODS OF TRANCE AND VISIONS — HYSTERO-EPILEPSY FOLLOWED BY PROLONGED TRANCE.

By ROBERT H. PORTER, M.D.,

Louisville, Ky.

Ernest B——, aged nine, was brought to my office on the morning of July 5th by his father. In a few moments he had an attack of petit mal that lasted just one minute. His father told me that two months previous his son had been run over by a street car, and in about four weeks afterward he was found sitting on a fence and unconscious. This state of unconsciousness lasted for half an hour. The next day he had several attacks of loss of consciousness, then these attacks became more frequent and at the same time were associated with a slight spasm. Three or four days after the first attack of unconsciousness the spasms changed to mania, which lasted for a week. During this time he was very violent, often attempting to commit suicide and to kill some member of the family.

After the mania subsided the spasms returned in the form of both grand and petit mal. Several days he would have as many as a hundred attacks of petit mal per day; then again they would be less frequent but more severe; often fifteen or twenty attacks of grand mal. Sometimes instead of a spasm he would have a short period of trance, and while in this state he would have a vision of God in Heaven with the Holy Angels, and would see the golden streets of the New Jerusalem. While in this condition he would usually talk all the time telling them of what he saw. After he returned to consciousness he would remember the vision, but did not know that he had been talking about it. Occasionally instead of a spasm or trance he would have a short period of frenzy or epileptic *furor*, in which he would attempt to do violence to himself or some one else. This condition of spasms, trance, and mania had continued for about three weeks preceding his first visit to my office. His father also told me that for three or four years he had been subject to a very severe cough, with frequent hemorrhages, and had been regarded as a consumptive; but for several months preceding his present illness his cough and hemorrhages had entirely subsided, with a corresponding improvement in his physical condition.

In two or three days after coming to see me he was quieted down, and his spasmodic trouble under very good control until July 11th, when his brother Claude was seized with a very severe attack of hystero-epilepsy. This excited him very much and caused the return of grand mal. The family bedrooms were adjoining, and while the boys were separated one would cry out and the other answer. This would be followed by severe spasms in each, one aggravating the other to such an extent that, on July 14th, it became necessary to remove Ernest from home to one of the infirmaries. Soon after leaving home he became quiet, and while in the infirmary, where he remained about a week, there was very little or no spasmodic trouble. He was taken from the infirmary to the house of a relative, where he remained two weeks, during which he continued to improve very nicely. At the expiration of this time it became necessary to return him home again. This increased his spasmodic trouble for a few days. Then he quieted down and continued to improve until August 13th, when he had an attack of acute diarrhœa, by which he was very much prostrated. In recovering from this on August 18th, he went into a trance that continued twenty-four hours. After recovering from this trance state he has continued to improve very rapidly up to the present time without any return of the spasmodic trouble.

On the morning of July 11th I received an urgent call to see Claude B——, a brother of the above patient. On entering the room he was found in a state of frenzy, barking and attempting to bite his attendants. Failing in this he bit himself a number of times. In a few minutes following this condition he had a general convulsion, with opisthotonos so extreme that the occiput touched the dorsal vertebræ, the patient resting on his face and feet. In a moment this condition was just reversed, with chin resting on his breast, limbs drawn up, and his knees touching his abdomen. He would continue this series of convulsions, first one form and then another, for five minutes; then remaining quiet for a few moments he would begin singing and growling with barking and attempting to bite his attendants or himself. During the barking and biting period he would go through all sorts of facial contortions. After watching him for a few minutes it was seen that he would go through a regular series of convulsions, and his condition was recognized as a severe attack of hystero-epilepsy.

Notwithstanding the use of appropriate sedatives, the paroxysms continued without cessation during the day, but he was quieted down as night came on and slept fairly well. The next morning the spasms returned, seeming to begin just where they left off the night before.

For two or three days he continued in this condition, but becoming a little more unmanageable through the irritation caused by his brother. On the morning of the 14th Ernest was removed from home, and then Claude became more tractable. During the first three days he was in a continual paroxysm all the time except while asleep. On the 14th it was found that the spasm so affected his throat that it was impossible for him to swallow anything, not even liquids; but by keeping him secluded the effect of the sedatives which he had already taken very freely was sufficient to control him. Gradually the convulsions became less frequent and severe, so that by the end of the first week they were under control. During this period he was unconscious all the time. As soon as the spasmodic trouble was controlled, he was found to be in a trance state. The second week of his illness he continued very vicious and combative; when molested in any way or approached by any one, he would begin snapping and attempt to bite them.

After the second week his vicious disposition subsided, and since then there has been very little difficulty in controlling him. During the first two weeks of his illness, owing to the spasm of the throat and his vicious state, it was so difficult to give him anything that he took very little food—the medicines needed to quiet him was about all he could be made to take—but since that time he has been taking food and medicine fairly well. It is now seven weeks since his first attack, and he is still in a state of trance; during the continuation of this trance state he has been exceedingly restless in the day, but sleeping fairly well at night from the effect of the medicines. He has not been able to walk any since the attack first came on. During the day he goes about the house on his hands and knees, with his eyes closed, and

during the early period of his illness, while he remained so vicious, with frothing of the mouth all the time, he seemed like a caged lion. There has at no time been any fever in the case, but occasionally he has periods of depression with cold extremities. Within the last day or two he has shown a tendency to a return of consciousness, he has a better expression, is inclined to open his eyes better, and on a few occasions has recognized and spoken to his attendant.

As usual in trance cases his eyes have been closed since the beginning of the attack; by using a little force they can be opened, and seem to be natural in appearance, only lacking the expression of intelligence. There has been no ophthalmic examination. If it were made it would probably show no abnormal conditions. There has been no paralysis or other indications of compression, or any other of the grosser brain-lesions. General sensibility seems to be somewhat exalted, and the usual reflexes respond to their appropriate tests. He hears sounds, and is very much irritated by noises in general, but has no comprehension of spoken words. He pays no attention to anything that is said to him. During the first week of his illness, when the spasmodic trouble was so marked, the unconsciousness was attributed to status epilepticus complicated with hysteria, but since the spasmodic condition has been controlled, followed by the prolonged trance, it is probable that the trance dates from the initial seizure.

The family history shows poor vitality, spasmodic troubles being in some of the collateral branches on the paternal side. His maternal ancestors have all died of consumption, his mother herself having been an invalid for several years, suffered with severe cough and frequent hemorrhages, but latterly her health has improved, and at the present time is in very good physical condition, except severe nervous headaches; the father has always been in good health. While at school, five months previous to his present illness, Claude received a blow in the left temporo-parietal region that stunned him for a while, producing confusion and loss of consciousness; but he soon recovered without any indisposition following it. He continued at school, without interruption, during the remainder of the session. On the 9th of July, two days before his present attack, his brother, in a state of frenzy, attempted to kill him, striking him a blow in the left eye, without doing any damage to the eye itself; he was dazed for a few moments, and from that time had several attacks of petit mal per day until he was seized with hystero-epilepsy.

These boys are the only children in the family. They have an inherent instability of the cerebral organization, and the present attacks of spasmodic trouble were caused by shock from the injuries. In neither case were the blows on the head sufficient to produce either fracture of the skull or concussion of the brain.

Aside from the complication of trance in one of these patients, hystero-epilepsy itself is seldom seen in this locality. Out of a large number of epileptics that I have had the care of, this is the first case seen; and out of a number of physicians who have seen these patients with me, none of them had previously seen a case.

217 West Broadway.

Exophthalmic Goitre and the Color of the Hair.—Referring to the question raised by Dr. Neal as to the color of the hair in exophthalmic goitre, Dr. E. S. Dunster, of the University of Michigan, writes: "I have at present under treatment a well-defined case of ophthalmic goitre, in which the hair is of a dark brown color, almost approaching black. In the few other cases (four or five in number) that have come under my observation, no record was made of the color of the hair. I have, however, a general recollection that in most of them the color was light; but to make such a statement definitely, unsupported as it is by recorded evidence, would carry little more weight than a guess."

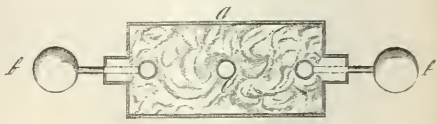
A METHOD OF PRODUCING OZONE IN LARGE QUANTITIES.

By ANDREW H. SMITH, M.D.,

NEW YORK.

The question as to whether ozone has any therapeutic value is still unsolved, owing probably in a great degree to the difficulties of production in quantity sufficient for satisfactory experimentation. An observation made by the writer in December, 1883, seems to open a way by which these difficulties may be overcome, and ozone produced with sufficient readiness to permit the study of its physiological and therapeutical action on an extended scale, and also its remedial use, if it should be found to possess curative properties.

Cotton wool, when deprived of its oil as in the preparation of "absorbent" cotton, is a sufficient conductor of static electricity to secure the diffusion of that agent through a considerable mass of the fibre placed loose



between the prime conductors of a static machine. If the experiment is tried in a darkened room the cotton assumes the appearance of a luminous cloud. A large surface of air contained in the cotton is exposed to the electrical action and a corresponding amount of ozone is produced.

The apparatus which I have had arranged as the result of the above observation consists of a glass cylinder ten inches long by five inches in diameter, and having a narrow neck at each extremity, through which a brass rod is passed connected with the respective prime conductor and terminated by a base. On one side of the cylinder and midway in its length is an opening an inch in diameter, and provided with a lip for the attachment of the inhaling tube. The cylinder is loosely filled with absorbent cotton and the balls attached to the rods from the prime conductors are introduced a short distance through the necks. The current is thus made to traverse the cotton, and when the machine is operated in the dark, the whole interior of the cylinder becomes luminous. The air drawn through the tubes is supplied by the openings at the ends of the cylinder, which are much larger than the rods which pass through them when a four-plate Holtz machine is employed. This air is so highly charged with ozone that it must be inhaled with caution. If breathed uncautiously it excites cough and produces a disagreeable irritation along the respiratory tract, and especially at the bifurcation of the trachea, which irritation may continue for several hours. Persistence in the inhalation would, no doubt, be followed by congestion or inflammation of the bronchial membrane.

The remarkable power of ozone as an oxidizing agent has led to the idea that it might be utilized in the treatment of disease, especially of a septic character. No definite results, however, have been attained as yet.

Dental Lesions of Morphinomania.—Dr. Combes states that there is a peculiar form of caries which attacks the teeth of those addicted to the use of morphine. It appears first on the triturating surface of the large molars and extends rapidly until a large cavity is formed. The bicuspids, incisors and canines are then attacked in succession. This form of caries is nearly painless, advances with great rapidity, and is unaccompanied by periosteitis. The dental lesions occur usually at the same time with the falling out of the hair.

A CASE OF DISLOCATION OF FIRST CERVICAL VERTEBRA—RECOVERY.

By H. R. CARTER, M.D.,
PASSED ASSISTANT SURGEON, UNITED STATES MARINE HOSPITAL SERVICE OF SAN FRANCISCO, CAL.

THE patient, a sailor, aged twenty, was admitted to hospital May 31, 1884. His companions stated that he had fallen from aloft that morning, a distance of about twenty-five feet, striking the back of his neck or head on a rope eight or ten feet above the water. When he struck the water he had a slight convulsion and lay motionless. He was unconscious and quite limp when picked up, but after coming to his senses had been jerking and stiff up to the time of admission, about six hours later.

Examination showed the occiput drawn well back and down as far as possible, the chin projecting forward but not raised. Not an extension of the head, but more like the position one would take expecting a blow on the back of the neck. Pain in the neck was continuous but not very severe, with the head in the above position and at rest. Pressure in the furrow behind the occiput was unendurable, producing great pain and a general tetanic condition.

The patient was continually jerking, and any handling, as in removing his clothing or even a decided touch, increased that condition, producing true though slight general spasms. The symptoms resembled those of strychnia-poisoning, save that the face was unaffected. The left arm was blue, cold, sweating profusely, rigid, and absolutely powerless. The right arm powerless, but less rigid than the left. The legs were not paralyzed but rigid and clumsy. Sensibility was at first present, but later was lost, and the patient was unable to swallow, even his saliva. Every attempt to bring the head forward produced unconsciousness. This occurred three times and during the examination, although the movement of the head was *very* slight. Consciousness was quickly, but not immediately, restored by bringing the head to its former position. While unconscious he was flaccid; on recovering there was a succession of spasms, the extensor muscles being very rigid. Pain was also produced in the neck, back, and arms, which gradually lessened on remaining quiet. The head was fixed only by muscular action, but the patient could not move it on account of pain. The finger being passed into the pharynx, a decided displacement of a vertebra forward was at once discovered at the upper part of the pharynx. The man was rational and not excited mentally, even during the spasms following unconsciousness. Everything seemed best explained by a dislocation forward of the first cervical vertebra on the second.

A full does of chloral was given by enema, and when the patient had come under its influence, I directed the nurse to lift up the head strongly, slightly extend it, and rock it very slightly. Pulling on the back of the neck with my left hand, I pressed with the thumb of the other on the projection in the pharynx, in a direction backward and upward, imparting to it at the same time as much of a rocking motion as possible. It was as much as a minute and a half before the projection began to yield; then it quickly but not suddenly moved into place; no click was heard or felt, but the head came up into position. The patient said "All right," before my thumb was removed from his mouth. A considerable amount of force was used, all, I believe, that I was capable of exerting. The head and shoulders were dressed on a pillow properly stiffened. He could swallow immediately. The twitching and rigidity disappeared in two and a half hours. The awkward, clumsy movements of the legs and arms disappeared the next day. The neck was painful and stiff for ten or twelve days, the man walking about at first with his head in his hands to steady it. The symptoms of vasomotor derangement in the left arm, viz., profuse sweating, cutaneous capillary congestion, etc., continued longer, and had not entirely disappeared at the end of sixteen days.

Clinical Department.

COCAINE IN THE EXTRACTION OF TOE-NAILS.

DR. W. T. SMITH, of Hanover, N. H., writes that he recently used cocaine in extracting a great toe-nail, with results that seem worthy of record in view of the ordinarily painful nature of this operation. He made four injections about the nail and then ran his needle under the centre of it. In a few minutes he thrust the blade of his scissors along the track of the needle and split the nail to its base and removed it with the forceps. The patient watched the operation, and said that it was absolutely painless. He used a four per cent. solution, and judged that fifteen or twenty minims were absorbed.

MAGGOTS IN THE EAR.

DR. W. FLETCHER WILSON, of Denver, Col., sends us the following history: Cora S——, aged twelve, called at office, July 25th, for relief of ear trouble. For nine years she had had a chronic discharge from the left ear. She had received no treatment, with the exception of simply syringing for the purpose of cleanliness. Two weeks previous to her calling at the office, she had been allowed a week's visit to some friends. While there the syringing was neglected. On her return home she complained of severe pain in the left ear. On application to family physician, a few drops were given, and a small glass syringe used, to cleanse the ear of the discharge. No relief, but increasing pain following, a consultation was called. She was then in a very weak and exhausted condition.

Examination showed a thin and bloody discharge from the ear, and a mass of maggots filling the external auditory canal. On touching with a cotton carrier, they would recede so as to almost disappear from sight without the aid of the speculum. After a few moments they would again come near the opening.

Using a pair of forceps, with serrated edges, two were removed. Springing from the head of each were two small, curved tenaculæ, about a line in length, with which they fastened themselves to the wall of the canal, so that when being removed they allowed of considerable stretching before loosening their hold. Each time, after removing one, the lively movements of the others, from being disturbed, caused such intense pain that, on removal of a second, the child fainted.

Syringing was then resorted to. Although using a very strong stream, I succeeded in removing but one. I then placed the child prone on the right side, and filled the diseased ear full of sweet-oil. After tedious waiting, I seized with the forceps each maggot as it came to the surface, and succeeded in thus removing seven, making in all ten. Pain ceased immediately after their removal. The canal was then thoroughly cleansed. Its inner third was entirely denuded of flesh; also, membrana tympani and mucous membrane lining tympanic cavity were gone. The bones of middle ear were so loosened that the malleus and incus were removed from the canal while being cleansed. Entire loss of hearing. Under the use of carbolic acid, three grains to the ounce, and frequent cleansing with cotton carrier, the discharge ceased and the parts recovered as far as possible.

The children had been in the habit of sleeping a short time each day under the shade of some trees. A fly, probably attracted by the odor, entered and deposited the eggs from which the larvæ were developed. Not being at home, the syringe was neglected and the eggs allowed to remain.

The above case well illustrates the necessity of cleanliness in ears suffering from chronic purulent otitis. When we take into consideration the tenacity with which the larvæ clung to the walls, and their manner of reced-

ing into the depths of the canal when disturbed, with my failure to dislodge them with a large syringe, it is not surprising the parents did not discover them.

The larvæ were about one-third of an inch long and one-twelfth of an inch thick. They seemed filled with blood. Two of them were killed; the other eight were placed in a two-ounce bottle, and a small piece of meat thrown in. After three days two more died. A little dirt was then placed in the bottle, and the larvæ at once buried themselves. In about two weeks four developed into very large grayish-black flies, about the size of horse-flies.

A CURIOUS MONSTER.

Dr. R. H. Spencer, of Peramo, Mich., writes: "I have recently attended a case of labor in which a female child was born, which is a curiosity. Child presented by the breech and was delivered after the usual method. The lower limbs are drawn up to the abdomen and there seems to be no action in the hip-joint, the knees look more like elbow-joints and are also anchylosed, the feet are an exaggerated form of talipes valgus, and at the union of the sacrum and lower lumbar vertebra there is an opening that looks very much like the anus, through which I could pass the end of my little finger, and on doing so it caused bloody serum to ooze from the rectum. The child is now three weeks old and doing well; the opening in the back has nearly closed. The question arises in such a case, as to the duty of the physician in keeping such a child alive. It was my wish to cut the cord and not tie it, but the family objected as they wished to have it baptized, they being Catholics."

SWAMP BUTTON-BUSH IN RHUS POISONING.

Dr. S. P. Hubbard, of Taunton, Mass., writes: "As I have never seen in any medical journal the virtues of the swamp button-bush (*Cephalanthus occidentalis*), for poisons of all kinds, especially *Rhus Tox.*, I wish to say to the medical profession that no remedy half equals it. Try it. Make a strong tea and freely bathe the parts with it while hot."

MENINGITIS AS A RESULT OF OTITIS.

Dr. E. E. Mather, of Williamstown, sends us the following history: On Monday, July 13th, at 4 A.M., he was called to see M. G——, farmer, aged thirty-three years, married; the messenger stating that he was in a fit. He found him in bed, having recovered partially from the seizure, but breathing heavily and still in a semi-comatose condition from which he could with difficulty be aroused, but exclaiming, when aroused, "My head! oh, my head!" Temperature 100°; pulse 70 and even; respiration stertorous; the pupil of left eye one-half smaller than the right pupil; there was ptosis of the lid of left eye; there was a peculiar immobile condition of the face; no paralysis.

His wife said that from an early age he had suffered from severe attacks of pain in the left ear, the attack resulting in suppuration, when the pain would be relieved. He had not consulted a physician for them. These attacks of otitis and otorrhœa were not continuous, but would recur on slight provocation. For two or three days before the doctor saw him, he had the earache (always the left ear), but continued his work in the hay field, and on Saturday he became very much heated in attempting to secure the last load from an approaching thunder-shower. The shower caught him and wet him through. That night and next day he suffered excruciating pains in the left ear, until at length the doctor was called. There was no outward suppuration; there was a moisture or sweating of and in the external ear. He recovered in some degree his consciousness, but there was constant tendency to sleep. There was almost total loss of memory. All food was refused; there was nausea and vomiting; bowels constipated. There was also a peculiar form of aphasia—he could not remember words: amnesic aphasia. For instance, he would beg me to give him some "epizootic." The pain in the head was confined to the left side; the same immobility of the features; ptosis of left lid and occasional profuse sweats. The temperature after the first two days ran not above normal, and sometimes under; the pulse grew slower every day until it reached forty-six; when aroused from his sleep, he would yawn and yawn; no paralysis at any time. This condition of things was maintained until the day previous to death, when his temperature was 101°, and pulse 72. No autopsy would be allowed.

Progress of Medical Science.

Supposed Rupture of Kidney.—A boy, aged fourteen years, leaped over a hedge, landing upon a lower level on the other side on his feet, but rolled over on his left side. He picked himself up and walked some distance, not complaining of pain. When he made water it was very bloody, and afterward vesical tenesmus was very constant. He was driven eight miles to the nearest town; on arriving he had recovered from the shock. He had pain and "severe spasms" over left ureter and kidney. He was treated by rest, liquid diet, gallic acid and opium, and ice locally, which relieved the pain over the kidney. Next day the urine contained less blood, sp. gr. 1.022. Microscopical examination showed traces of broken tubules, no renal epithelium; there was a swelling over the site of the left kidney; temperature normal. Six days afterward the urine was clear; occasionally there was a slight trace of albumen. He returned to school in a month. Dr. Campbell, who had the case under observation, believed that the accident occurred by the kidney being pinched between the false ribs and the ileum, or that the weight of the kidney was sufficient to lacerate some of the vessels in the cortical substance.—*Liverpool Medico-Chirurg. Jour.*

The Functional Condition of the Leg after Transverse Fracture of the Patella.—In a paper read at the French Congress of Surgery, M. Richelot, of Paris, holds that, when persistent lameness follows transverse fracture of the patella, such condition is due not to separation of the fragments of the bone, but to atrophy and consequent loss of power of the quadriceps muscle. There are many subjects of old fracture of the patella who, notwithstanding separation of the fragments to the extent of nearly four inches, are able to walk about and to ascend and descend stairs quite as well as though the bone were normal. It often happens that the functional power of the injured limb improves the more as the separation of the fragments continues to increase. When the rectus muscle has lost a fixed point of insertion, and can play but a very slight part in extension, there remain the two vasti muscles, the inferior attachments of which are never torn through. It is necessary, therefore, in cases of fracture of the patella, to prevent, if possible, any atrophy of these muscles. The first muscle to waste is the rectus, then the vastus internus, and, finally, the vastus externus. The atrophy is of the same nature as that resulting from arthritis, or from any other articular lesion. M. Richelot holds that, in the treatment of fracture of the patella, it is more important to prevent wasting of the extensor muscles than to attempt to bring the fragments together. Most surgeons, he states, have seen examples of good locomotion, with considerable separation of the fragments, and other examples of extreme lameness with the fragments in close or even immediate apposition. This absence of relation between the extent of the pseudarthrosis and the degree of functional impairment, indicates that wide separation of the fragments

is not the essential element of the loss of power of the limb. Atrophy of the quadriceps muscle, varying much in extent in different cases, but of very common occurrence after fracture of the patella, is the main condition on the intensity and persistence of which depend the intensity and persistence of the functional impairment of the limb. Separation of the fragments certainly impairs the extending action of the rectus, but this muscle does not form more than a fourth part of the mass of the quadriceps, and the two vasti muscles always remain attached to the sides of the inferior fragment, and, therefore, if not atrophied, are sufficient to maintain the functions of the limb. When the lateral fibrous structures remain intact, and there is not an absolute solution of continuity between the thigh and the leg, it is useless, M. Richelot argues, to endeavor to bring the fragments together by a multiplicity of apparatus, or to perform arthrotomy, which, not to speak of its dangers, seems superfluous if the quadriceps be normal, and illusory if it have undergone atrophy. In the treatment of fracture of the patella, after the limb has been fixed in a simple apparatus and the most simple means of bringing the fragments together have been applied, the surgeon's attention should be mainly directed to the quadriceps muscle.—*London Medical Record.*

Successful Cerebral Surgery.—In *The Lancet*, May, 1885, Dr. Macewen reports the case of a man, aged thirty-six, who in August, 1883, fell downstairs, and was rendered unconscious for twelve hours. In November, 1883, the patient was admitted into the Glasgow Royal Infirmary, with impairment of power in the left arm, accompanied by muscular twitchings and pricking sensations in some parts. A lesion was diagnosed in the motor cortex of the upper half of the right ascending frontal convolution, probably due to irritation set up around an extravasation of blood, due to the previous injury. In December the author trephined, and found a membrane-like patch over the surface of the brain, involving the arachnoid and pia mater along with the external surface of the gray matter; there was also blood effused into the substance of the brain in the ascending frontal convolution. All this was removed, the bone was replaced after having been broken up into several small pieces, and the wound was dressed with eucalyptus gauze. The patient made a perfect recovery without a bad symptom, and two months afterward was able to do his ordinary work.

Sacculer Dilatation of Urethra.—Lawson Tait relates a case, which he published in *The Lancet*, October, 1875, of a lady, who suffered from a sacculated dilatation in the floor of the urethra. Until the beginning of this year, the author states, he had never seen such a case, but during the past three months he has met with three cases almost exactly similar. The symptoms in all were precisely alike. There was a constant escape of fœtid ammoniacal purulent urine, which did not occur always on ordinary micturition, but only when there was any strain, or upon pressure, or change of position, and sometimes quite independently of the patient's control. On examination a tumor was found, apparently continuous with the neck of the bladder, presenting itself between the lips of the vestibule, closely resembling an ordinary cystic vaginocele. When a catheter was passed along the roof of the urethra, it went into the bladder and clear urine was drawn off; but, if passed along the floor of the urethra, it entered the cavity of the tumor, bringing away putrid urine. On each case, the author operated with complete success. This form of disease is stated to be, most likely, due to an error of development, by which a small offshoot of the urethra, like a diverticulum of intestine, is the result of faulty union of the primal folds; and this becomes of pathological importance when women become accustomed to those errors of urination to which they are all more or less addicted. —*British Medical Journal.*

Communicability of Tuberculosis by the Genito-Urinary Organs.—Dr. Settier narrates five cases, in which the contagion of tuberculosis was probably communicated by the genito-urinary organs. The first, a man, aged thirty-eight, with no family history of phthisis, contracted a disease of the prostate after marriage with a phthisical girl who had a constant leucorrhœal discharge, which discharge was found to contain numerous tubercle-bacilli. The pus from the man's urethra also contained unmistakable tubercle-bacilli. The second case was that of a healthy young man, aged twenty-nine, in whom, four years after marriage with a phthisical woman, there were swelling of the left testicle and epididymis, and enlarged prostate. The diagnosis was established by the recognition of tubercle-bacilli in pus from the urethra. Case three, was that of a woman, married to a phthisical man. After marriage she suffered from leucorrhœa, vulvo-vaginitis, and pelvi-peritonitis. When admitted, she was suffering from tuberculosis of the lungs, tongue, and ear. In case four, a negress, whose husband died of phthisis, suffered from a vast tuberculous abscess of the pelvis, with commencing mischief at the apex of the right lung. In case five, a man, aged twenty-nine, suffered from pulmonary and laryngeal phthisis. The right testicle, and especially the epididymis, was enlarged. This he attributed to an orchitis, which he had long before the chest was affected. —*London Medical Record.*

Fish-poisoning and the Fish-poison.—The supposition that fish-poison is a ptomaine, and that fish-poisoning is ptomaine-poisoning, receives confirmation through the researches of Professor V. K. Anrep, of Kharkov. During February and March, 1885, there occurred in Kharkov several cases of poisoning by salted sturgeon, five of which ended fatally. The author succeeded in isolating ptomaines (after the methods of Stas and Otto, and of Brieger) (*a*) from the sturgeon which had caused poisoning; (*b*) from the gastro-intestinal contents taken from one of the fatal cases; (*c*) from the liver, blood, brain, and spleen taken from the same fatal case; and (*d*) from the urine of another deceased patient. All the ptomaines proved quite identical in regard to their physical and chemical properties, as well as in regard to their physiological action on animals. Anrep's fish-ptomaine is an amorphous solid body, of strongly pronounced alkaline properties, and of highly toxic power. It dissolves in water only with difficulty, but gives salts which are readily soluble. These salts may be brought to partial crystallization (*in vacuo*). Under the influence of caustic alkalies, acids, and boiling, the fish-ptomaine undergoes decomposition and loses its toxic action. The characteristic peculiarities of the alkaloid are two: (*a*) its stability (the ptomaine in substance as well as its ethereal solution did not suffer the slightest change in its chemical and physiological properties even after a month's keeping); and (*b*) its slow action on red blood-salt, the reduction of the latter being effected only in three to six hours. The author carried out a series of physiological experiments to elucidate the action of his ptomaine on animals. In dogs, a hypodermic injection of a quarter of a milligramme of hydrochloric salt rapidly produced sickness, vomiting, moderate dilatation of the pupils, then dryness of the mucous membranes, thirst, and general prostration; in about two hours there appeared retardation of the respiration, weakness, and slight retardation of the cardiac action, and considerable failure of reflex action. The symptoms lasted for about ten hours, and then the animal pretty rapidly recovered. In rabbits, the identical injection produced considerable dilatation of the pupils, very considerable retardation and difficulty of respiration, progressive weariness of the cardiac action; an hour later, paresis of the hind limbs; and in two hours, death from simultaneous arrest of the heart and respiration. In frogs, an injection of a dose much smaller than a fourth of a milligramme (0.0038 grain) brought about paralysis, loss of reflexes, dilatation

of the pupils, failure and retardation of the cardiac action and respiration, and, on the second or third day, death. The symptoms of fish-poisoning in man presented a nearly complete likeness with those produced in animals by Anrep's fish-ptomaine. Within three to six, not later than twenty-four hours after the ingestion of poisonous fish, there appeared malaise, sickness, giddiness, then pain in the stomach, vomiting, paleness of the face, dryness of the mucous membranes of the mouth and tongue, thirst, failure of sight, ptosis, dilatation of the pupils, coldness of the limbs, labored respiration, feeling of oppression in the chest (especially in the præcordial region), weak and small pulse, difficult swallowing, considerable prostration, slight decrease of the temperature of the body. In the further course of the fatal cases, the cardiac action markedly grew weaker and weaker, the respiration became more and more difficult, prostration and ptosis increased, the temperature fell lower; then appeared cyanosis, retention of urine and fæces, slight œdema of the face, indistinctness of speech, weakness of voice. On the second, sometimes on the third or fourth day, death ensued. Analyzing the list of the symptoms, Professor Anrep points out that the fish-poison paralyzes the spinal cord and medulla oblongata; probably also the unstriated muscular tissue.—*London Medical Record*, July 15, 1885.

Carcinoma of the Cerebellum with Scirrhus of the Lung.—Cantani reports the case of a woman, aged forty-five, who had occipital headache, rigidity of the back of the neck, inco-ordination of movements, progressive loss of the mental faculties, vomiting, tendency to fall backwards, and frequently also slowness of the pulse and respiration. The emaciation, vomiting, and epigastric pains might have given rise to the suspicion of cancer of the stomach, but the symptoms generally were those of a lesion of the cerebral nervous system, and the diagnosis made was that of tumor of the cerebellum. At the necropsy a small abscess, limited to the cortical substance, was found in the right parietal lobe, in correspondence with the first parietal ascending convolution; in the right lobe of the cerebellum was an abscess, of the size of a walnut, and in the left lobe of the cerebellum another abscess, of the size of a filbert. In the upper lobe of the right lung there was a nodule of scirrhus as large as an apple. During life there were no other signs of pulmonary lesion than raised percussion-note and prolonged respiration in the right superior lobe. The author supposes the abscesses were the result of suppuration from neoplastic foci of carcinomatous nature, developed in the brain, and that the pulmonary scirrhus was secondary.—*London Medical Record*.

Accessory Suprarenal Capsules.—Chiari describes four cases under his own observation, and proves that accessory adrenals may be found in males as well as in females, and in adults as well as in children; they do not undergo atrophy in youth, and lie between the kidney and the testicle or ovary. In one case, a large tumor was removed by laparotomy from the abdomen of a man aged forty-four; it lay between the right kidney and the brim of the pelvis, upon the quadratus lumborum and iliacus internus muscles, external to the psoas, and behind the cæcum and the peritoneum covering the right iliac fossa. It was invested with a capsule intimately connected with neighboring structures. Dr. Chiari looked upon the tumor as proceeding from an accessory adrenal, but consisting of irregularly-arranged adrenal tissue, and therefore cancerous. In support of his opinion, he notes that it grew in a region where accessory adrenals are found, and possessed a complete capsule, as is only the case in growths of a similar consistence and rapid growth, when they originate within an organ that has a true capsule. Grawitz has described new growths developed from healthy accessory adrenals. The characters of sections of the tumor examined by Dr. Chiari resembled, microscopically, normal adrenal tissue. Groups of characteristic pigmented cells, infiltrated with fat, were found, precisely similar to those seen in the substance of the suprarenal capsule. The tumor recurred, its substance bursting its capsule and invading neighboring organs.—*London Medical Record*.

Acute Suppuration after Forcible Rupture of Articular Adhesions.—Professor Oberst reports four cases from the hospital practice of Volkmann, on which acute suppuration followed the breaking down of articular adhesions. In each of these cases, the ankylosis had followed an acute infective process. In two cases the primary affection was acute articular rheumatism, and in one the ankylosis was the result of acute infective osteomyelitis. In the fourth case, the nature of the primary affection could not be clearly made out, but there is no doubt, Oberst states, that it was some acute infective process. In two cases, the suppuration caused by the breaking down of adhesions—in one in the cuticle, in the other in the knee—did not extend beyond the affected joint, while in the other two it was very extensive, and caused much disorganization, necessitating amputation of the thigh in one of these instances, and causing death in the other. In the last case, which was one of ankylosis of the knee and deformity after acute rheumatism, forcible extension of the limb caused infraction of the inferior epiphysis of the femur, and was rapidly followed by acute and typical osteo-myelitis, with necrosis and formation of multiple abscesses in the medulla. Oberst thinks that the multiplicity of the abscesses, the character of the necrosis, and other morbid conditions in this case indicated that it was one of specific infective and not of simple septic osteo-myelitis, and it is suggested that it might have been due to the action of the poison of acute rheumatism. There can be no doubt, it is held, that in each of these four cases the suppuration set up by relatively slight force may be most readily explained by the supposition that, from the date of the primary acute affection during disease, germs had been left in the affected regions, and that, by the attempt to restore the functions of the joint, they had again been rendered mobile and placed under conditions favorable to the restoration of more active vitality. In each case, the patient at the time of operation was quite healthy—except with regard to articular deformity—and free from fever, and in not a single instance did any abscess or fistula exist at this stage. There could not, it is stated, have been any infection from without, as the integument in each case was quite intact, and the extravasation of blood caused by the forcible movements of the joint did not reach the surface. These cases, Oberst points out, should teach surgeons that they ought to be very cautious in attempting to break down ankyloses which have resulted from acute infective diseases. In cases of this kind, a cutting operation would certainly be less dangerous than forcible rupture of the adhesions by simple manipulation. In not one of the very numerous cutting operations that have been performed with orthopædic aims at the Oberst Hospital at Halle has any instance been observed, Oberst states, of complication due to infection. It is supposed that the micro-organisms remaining after the primary disease find a much less favorable soil in the disinfected and antiseptically-treated operation-wound than in contused and lacerated tissues, and in abundant or diffused extravasations of blood, conditions which often exist after forcible attempts to restore the functions of an ankylosed joint.—*Centralblatt für Chirurgie*.

Relief of Cramp of the Uterus during Labor.—For relieving cramp of the uterus during parturition, Dr. Svanberg employs a compress, soaked in a mixture of chloroform and olive-oil, equal parts of each, or two parts of chloroform to one of oil, applied closely to the abdomen, between the umbilicus and the symphysis pubis. He has found the result to be immediate relief of the spasm, even when the previous inhalation of chloroform has failed.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, September 5, 1885.

THE PATIENT AND HIS CHOICE OF DOCTORS.

THE relation of the patient, family doctor and consultant is discussed in a recent number of the *London Lancet*. The editor regrets the increasing tendency of the patient to seek consultation independent of the family physician, and the decline which the present day witnesses in the esteem in which this personage is held. The patient takes his affairs in his own hands, and goes from one to another in search of opinions, which may actually, or according to his notions, differ in many instances. This tends to throw discredit on the profession and create a distrust in its judgment. The writer says: "It is well worthy of consideration of consultants and patients whether a system so mischievous should not be abandoned."

As it is impossible to discipline patients so that they will seek advice in only one direction, the plea is made to consultants. Their discourtesy to the family physician is pointed out, the coolness which will arise between them, and the disturbance of friendly feeling between the family and the physician. The injury done to patients themselves, because of the conflicting diagnoses which are liable to occur, is also shown. It tends to merge the consulting physician into the specialist, whose attention is too apt to be concentrated on the localized disease, unless the family physician interfere in behalf of his patient. A diagnosis, too, may be made without due deference to the family history. Moreover, the patient sees his consulting physician seldom, and makes use of his medicine for a long time when it is no longer appropriate.

In all this there is, indeed, more than a modicum of truth; but there is also an obverse to it worthy the consideration of the "family physician," if not "the consultant" and "the patient."

It is true we are living in a different age from a generation or so ago, when clergymen and doctors were institutions which ran parallel with the lives of families, fixed and immutable, until summoned

> "To join
> The innumerable caravan which moves
> To that mysterious realm where each shall take
> His chamber in the silent halls of death"

Independence of thought and feeling are rife in every department. Scepticism is a ghost not to be laid, and plays the mischief with the once honored "family physician," who now holds no sinecure, but must prove his right and title to the office by his display of skill and intelligence, and the power he has of convincing his clients that he is abreast with the times. *The Lancet*, with praiseworthy conviction, assumes that the "family physician" is infallible. It has not the slightest misgiving that by any chance he may be a fossil, who is liable to err, who has a pompous reliance on his own judgment, and if questions arise will bring in a friend who will support his view of the case, and will not in any event go counter to his wishes. The patient becomes a shuttlecock tossed only to and fro between the battledores of their two opinions, to their edification but little to his benefit. Tied up with the red tape of etiquette, there can be no interference. The amicable relations of the physician must not be disturbed, nor that of physicians and families. The question of the patient's welfare is one of minor consideration.

It is at best a delicate relation which a physician holds toward a patient. That of the clergyman is nothing in comparison. The hypothetical soul and its treatment disturb its possessor very little for the most part. The property of the individual comes nearer to him, and he selects his lawyer according to his purse and his opinion of ability. The body, although a living, every-day palpable reality to its owner, is more mysterious and incomprehensible than either of the two—that is, if it gets out of order. He is buffeted with notions of how to take care of it. And though the words of the Sphinx, "Know thyself," sound ever in his ears, he is conscious it is a riddle that he never can solve, and puts the solution into the hands of his doctor with more blind faith than he leaves his soul with his clergyman, or his property with his lawyer. It is no wonder that he has misgivings, and that he wanders from oracle to oracle in the hope of enlightenment. It is well to warn him against such a course, as confusion becomes more confounded, and, as *The Lancet* justly observes, little good can result to him.

The Lancet blames the consultant, and with some show of justice; nevertheless we do not think that his position is sufficiently considered. If he is the doctor he ought to be, he should feel that the patient could be benefited by no counsel as well as by his; for no physician, to take the highest view of the case, should practise until he feels that he is competent to do as well, nay, even better, than any one else. Such being the case, it is depriving humanity of its rights to withhold his opinions and treatment when applied to for them. Especially as the patient, for the time being, at least, is of the same mind. Why should an iron-bound etiquette interfere? Why has not the patient the same right to go from doctor to doctor as to go from shop to shop in search of an article to suit him in quality and price? to go from church to church to find the clergyman whose sentiments, oratory and rhetoric please him? to go from lawyer to lawyer to find the one who will best plead his case and preserve to him his property? He may err in judgment in all these; he has the same liability to err in the matter of his doctor—doubtless will; but why should it be a matter of personal offence between physicians any more than between merchants, clergymen, and lawyers, who

do not bind themselves together with any such notions of etiquette?

The golden rule of doing unto others as one would be done by should certainly be observed in all relations, and among doctors especially. The consultant should not feel that it is his especial duty, as he often does, to alarm the patient in regard to his previous course of treatment, and however much the doctor may think it, it is not quite kind to the absent to tell his patient that up to the time of his fortunate meeting with him all had been wasted and worse than wasted that had been done. Moreover, he should remember to take *cum grano salis* the remarkable statements of the patient relative to anatomical facts and diagnosis, ever bearing in mind that what he says may be interpreted in the same way to some one else, and that a broad mantle of charitable consideration is due to his brother practitioner, who would doubtless be as much astonished as any one at the form his statements had assumed.

In these respects, therefore, we must differ with *The Lancet*, and come to the conclusion that a plea is not so necessary for the family physician as for the consultant, who has by far the heaviest burden to bear in the task put upon him to behave like a Christian and a brother, and above all for the patient, innocent as a lamb, who finds in any case perplexity and distrust, since he comes to a market to purchase wares concerning which he knows little or nothing.

MASKED ARTICULAR RHEUMATISM.

Considerable attention has been paid of late years to various forms of latent rheumatism in which the disease does not manifest itself primarily or solely in the articulations, but in which other organs and tissues are attacked, to the exclusion even in certain cases of the joints. In children, as is well known, the articular implication is often so slight as to pass unnoticed, and perhaps the nature of the disease is never discovered, or it is learned only when the heart symptoms declare themselves. But it is not to such cases as these that we wish to refer, but rather to those in which some other structures are attacked primarily, giving rise to symptoms well calculated to deceive any who do not remember that rheumatism is a general disease, and not an articular affection.

We have already noticed in these columns a pulmonary form of rheumatism described by M. Lebreton. This occurs in individuals, belonging to a rheumatic family, who may or may not have previously suffered from the articular form of the disease. There are three principal varieties, the pneumonic, the œdematous, and the congestive. The symptoms of the first variety are not those characteristic of true pneumonia. The face is pale, and the stethoscopic signs are fugitive, not being confined to one lobe or one lung, but changing about from one lung to the other, or from the apex to the base, with most perplexing irregularity. In the œdematous form there is pallor of the face, respiration becomes suddenly labored, and the ear applied to the chest hears râles in every part. In both these varieties the skin is constantly bathed in a profuse acid perspiration. The congestive form occurs under three clinical varieties. There may be frequent hæmoptyses without any other evidence of pulmonary lesion, or there may be repeated attacks of dyspnœa equally inexplicable by any intrathoracic disease. Lastly, there is the latent variety, giving rise to no special subjective symptoms, and characterized simply by a sound resembling the crepitant rale of pneumonia, heard only in inspiration.

In a communication addressed to the Paris Academy of Medicine some three years ago, Dr. Maurice Perrin related a number of instances of conjunctivitis due to rheumatism. This affection resembles, in the rapidity of its development and the gravity of its symptoms, gonorrhœal ophthalmia, and the integrity of the cornea is often seriously endangered. There are, however, certain forms of less severity, not purulent, and resembling simple catarrhal conjunctivitis.

Certain cases of epilepsy have been referred by Tiessier, of Lyons, to the influence of the rheumatic poison. He has seen persons attacked with epilepsy for the first time while they were suffering from articular rheumatism, and others who were epileptic and had never had any of the joint manifestations, but who came from a rheumatic family. These cases were all promptly cured by appropriate medicinal treatment.

At the Congress of German Physicians, recently held in Wiesbaden, Dr. Immermann, of Basle, said that he had repeatedly, in recent years, met with cases of acute neuralgia of the fifth nerve, due to the action of the rheumatic poison. That they were referrible to this cause was shown by their clinical course, by the fact that they occurred at a time when acute articular rheumatism was epidemic in Basle, and, lastly, by the effects of treatment. The cases were accompanied by high fever (in one instance of 104° F.), and in some there were secondary heart lesions. The pain was intense, and was located in one or other branch of the trigeminus, but the impression given to the observer was not that of a purely local neuralgia, but the affection seemed, in some indescribable way, to be rather part of a general disease. The neuritis yielded readily to salicylate of soda. Dr. Edlefsen, of Kiel, remarked that he had also met with similar cases of trigeminal neuralgia of rheumatic origin, which had promptly subsided upon the exhibition of salicylates.

These forms of rheumatism are evidently analogous to the latent manifestations of the malarial poison, and their treatment is to be conducted in the same way, by the exhibition of the specific remedy. Now that the existence of these masked forms of articular rheumatism, as they are designated by Immermann, has been demonstrated, their number and variety will doubtless be largely increased by successive observers, and perhaps many affections which are now so rebellious to treatment will be found to belong to this category, and, their true nature being known, they may be seen to be more readily curable than has hitherto been supposed.

AN AMERICAN DAVOS.

The physiological and therapeutical effects of high altitudes and a winter climate have been very carefully studied by European physicians, largely because of the good practical results secured by invalids at Davos, in the Engadine, and at similar places in Switzerland.

Davos is situated in a valley at an elevation of 5,400 feet, at latitude 47°. The physical conditions there which produce the results observed in consumptive invalids are: 1, Great elevation above sea-level; 2, a continuous and, during winter, permanent covering of snow; 3, a minimum of watery vapor in the air; 4, a clear sun; 5, a clean atmosphere, free from zymotic germs, dust, and fog; 6, a sheltered position, favorable for receiving both the direct and reflected solar rays.

As in all high altitudes, the solar radiation is very intense. It is a fact that with increase of altitude the sun-temperature rises while the air-temperature falls. At Davos, for example, the sun-temperature is from 89.2° to 108°, while the air-temperature may be near zero.

Dr. Hermann Weber summarized the physiological effects of such a high, cold altitude as Davos in a series of lectures delivered in London last winter:

1. Increased activity of the skin, better nutrition and invigoration of the skin.

2. Strengthening of the heart and the contractile fibres of the vascular system, with augmented frequency of the heart's contractions at first, but reversion to the normal state after a longer sojourn, together with greater force of each contraction, and thereby increased suction-power.

3. More rapid respiration at first, but return to the normal rate after a few days. Probable increase of depth of inspirations. Strengthening of the respiratory muscles, and probably also of the elastic fibres of the finest bronchial branches. Increased flow of blood through the lungs.

4. Generally a marked increase in the excretion of water through the lungs, and increased and facilitated excretion of carbonic acid.

5. In most cases transient or continued increase of appetite, ingestion of food, digestion, and assimmilation.

6. Thereby improved production of blood and nutrition of the organs.

7. Greater energy of nervous and muscular action.

8. In most cases improvement of sleep.

9. Probable augmentation of tissue-change.

Dr. Edward Frankland, president of the Royal College of Chemistry, has called attention in the *Popular Science Monthly* to the fact, as he believes, that the United States has in the Yellowstone Park a climate quite equal, if not superior, to that at Davos. The great plateau of this park is between seven thousand and eight thousand feet above sea-level. The mountains about it are from ten thousand to twelve thousand feet high. The period of permanent snow is longer than at Davos, the latitude a little lower, viz., 44° to 45° parallel, and there are plenty of places where a free horizon southward can be obtained; in all these respects the park being superior to Davos.

Dr. Frankland's opinions are based upon a hasty visit, and are mainly suggestive in character. It is well for physicians to know, however, that there is an American Davos in their reach. The badness of the accommodations for the present prevent any utilization of the park by invalids. Some studies must be made also upon the very important factor of the quality of the soil.

THE INDICATIONS AND METHODS FOR RADICALLY TREATING HERNIA.

The question of the propriety of attempting a radical cure of hernia by operation is a frequently recurring one. The importunities of patients and the ambition and ingenuity of surgeons combine to this result. Despite the most strenuous arguments, however, in favor of various methods for radically relieving hernia, it is still the general opinion of surgeons, that for the vast majority of cases we have yet no safe and sure method of cure, and that the routine or even frequent performance of the so-called radical operations, except for "congenital" cases, is not justifiable. An interesting review of this subject has recently been given by Mr. John Wood, in a series of lectures delivered before the Royal College of Physicians. Mr. Wood has identified himself with the advocates of radical operations, and has himself devised a method which is familiar in name, though not perhaps in detail, to readers on this side of the Atlantic.

In the past twenty-seven years Mr. Wood has operated upon 370 cases of inguinal hernia, with four deaths. Of those whose after-history is recorded, considerably over half are stated to have been permanently relieved.

Perhaps Mr. Wood's operation has not yet been duly tried in this country. It is certain, at any rate, that it has no popularity among surgeons here. Undoubtedly surgical opinion just now favors some of the various open methods advocated by Banks, Annandale, Alexander, Stokes, and others. Perhaps some of these plans approach dangerously near in practice to the old mediæval methods of simply tying the neck of the sac, and either cutting it off or leaving it and the sides of the canal to heal up as they lie. But however this may be, the "open operation," when carefully done, seems to have very little danger and to give good results.

Although, as we have stated, surgical opinion is still very conservative as regards operations for the radical cure of hernia, yet it does not follow that in the future these operations will not be much more regularly and extensively performed. Mr. John Wood, in the lectures referred to, gives a list of the indications for the radical operation, of which our London correspondent has presented the main features to our readers. (See Medical Record, July 4th.)

"It appears indubitable," Mr. Wood says, in concluding, "from the results of the last twenty or more years' experience of the radical cure of hernia, that the position of those surgical writers who have maintained that the radical cure should not be attempted, except in the severest cases, is untenable."

INSANITY AND DIVORCE.

We believe that there are some States in which insanity is admitted as a ground for divorce; but throughout the world the contrary rule holds in civilized countries. Every physician sees, at times, cases where this state of things is the cause of a life-long burden and unhappiness. And it is not unnatural that the question should be raised, at times, if the law as it exists is right. In a recent number of the *Medico-Legal Journal*, Dr. George H. Savage, of London, discusses the subject at length, and cites three cases as illustrating the condition and working of the English law.

Dr. Savage upholds the present law and practice—that insanity occurring after marriage should not be held as a ground of divorce. Indeed, he is so positive on this point that he thinks that arguments in its favor are unnecessary. Because a man has made a bad bargain is no reason, he says, why he should break the bargain. He as an individual must suffer for the good of society; besides it is very difficult to say that any given insane man or woman will never recover. These are the grounds which Dr. Savage indicates as those upon which he bases his opinion. For the present, Dr. Savage's view and the common law should undoubtedly stand, for progress in such matters must be careful and slow. But we feel certain that after a time the people and the law-makers will see that society is not benefited by a law which binds a man or woman for life to a chronic lunatic. In a large per centage of the cases of insanity which have lasted four years a commission of experts could safely and surely pronounce the disease incurable. Besides, if in some phenomenal and extraordinary instance the decision were wrong, would the harm in this rare and almost impossible instance be proportionate to the happiness conferred in many other instances?

While we are not ready, therefore, as yet, to take the ground that chronic, incurable insanity should be admitted as a ground of divorce, we cannot praise the perfunctory manner in which Dr. Savage dismisses the question.

The law with regard to insanity and divorce now is very much like that with regard to insanity and crime. One of the contracting parties may have been insane before or after, perhaps even at the time of, the marriage contract; yet this is not a ground for annulling it. Such ground only exists when it is proved that the party, at the time of the marriage, was of such unsound mind as to not know and understand the nature of the act. Dr. Savage cites two cases—one of them, that of Lord and Lady Durham, a true *cause célèbre*—which illustrate the working of the English law—and very bad work it is, too. In both cases insanity developed in marked manner directly or soon after the marriage, and in both cases the existence of mental unsoundness before the marriage is evident to a medical expert. Yet divorce was denied, because it could not be proved that at the time of the marriage the contracting party did not understand the nature of the act.

It may be that this English test is the only practicable one, considering all things, but it is certainly, from a scientific standpoint, irrational; and we see no reason why it should not be repudiated here by medical men, as it has been done in its application to criminal acts. The real question should be whether the person was mentally diseased at the time of the contract.

We confess to feeling a little surprised that Dr. Savage should allow his cases, which show so glaringly the injustice of the law, to go without more critical comment.

THE MORAL DANGER OF THE AMERICAN MEDICAL PROFESSION.

There is no denying the fact that the profession of this country is subjected to what we may term a moral strain that is greater than is experienced in older countries. The multitude of half-formed doctors turned out by our schools, the fierceness of competition, the American passion for "practical" and business-like methods, the haste for success, all tend to tempt the younger physicians especially toward a laxity in conduct. Considering all these things, it behooves every conscientious physician to keep a careful watch upon himself. His responsibility is very great. Although the practice of medicine has already assumed many of the features of a "business," it is not, and, as we have before said, never can, by honest men, be carried on just as a trade would be. Having to do only with the body and its ills, no physician of any conscience and human sympathy can fail to regulate his conduct on a higher plane than that of the simple *quid pro quo* of the tradesman.

Yet, unfortunately, it appears that men without conscience do get in our ranks, and even attain some standing there. It is against these that the profession must be on its guard. We have too long regulated what is good and praiseworthy in the physician by standards that are, in a measure, false and artificial. There have been times when a man, however sincere and honorable, would be looked at askant if he used electricity or massage, or pushed a probang down the larynx.

It behooves a doctor now to judge his fellow by high standards of Christian morals, and by these alone. He should be true to his patient, his colleagues, and himself. Such conduct should be the gauge of professional loyalty, and such conduct very much needs cultivating.

PERSONAL MEDICAL NOMENCLATURE.

We propose to give our readers a little insight into the present condition of medical nosology, or at least into one phase of it. It will be very readily agreed that the human body has diseases enough, and that medical literature has technical terms enough; and we shall probably not find it hard to show in this, and succeeding articles, that these terms are accumulating upon us altogether too rapidly. Medical technical terms have in the past been largely a matter of chance, and they are now in some considerable degree a meaningless jumble of personal appellations, bad Latin, and worse Greek. We have had no tribunal in the past for determining what is appropriate as a name, and hence students of the present day are visited with the sins of their forefathers back to remote periods of time. One of the most glaring excrescences which is fastened upon medical nomenclature is that which attaches to anatomical parts or pathological processes the name of its supposed discoverer. It is to this that we would call attention now, and more particularly to the diseases which, in medical writings, generally receive the name of their first describer. In protesting against the practice of identifying a morbid process by a historical name, we do not wish to deny that there is in it a measure of justice. Nor would we insist too strongly upon its confusing and misleading effects, as illustrated last fall, for example, by the darkey who refused to vote for Blaine, and gave as a reason, "He ain' no 'onest man; he's got Bright's disease, an' why do'ne he give it back to Mr. Bright." But certainly, as a practice, it has become already an encumbrance, and it is time we should cry a halt. We doubt if our readers are quite aware of the number

of diseases which are carrying their discoverer's name to immortality. Neurology seems to have taken the lead, although the names are not always those of neurologists, while among races it is the French and English who lead in the department of personal nosology. Duchenne has had three diseases named after him, but by Duchenne's disease we generally mean locomotor ataxia. Paralysis agitans is also known as Duchenne's disease, while the Duchenne-Aran type of muscular atrophy is the name applied to the ordinary (spinal) form of progressive muscular atrophy.

Exophthalmic goitre is claimed by two countries and five individuals, and is called, according to the particular penchant of the writer, Parkinson's or Basedow's, Graves', Marsh's, or Parry's disease. Dubini's disease is a peculiar and fatal form of chorea (chorea electrica); Thomsen's disease, which is really a congenital defect of development, consists of peculiar attacks of rigidity of the voluntary muscles; Little's disease is the spasmodic tabes of children. Diabetes has been known as the disease of Willis. Charcot has two diseases named in his honor—the joint disease of tabes and amyolateral sclerosis; Bright's disease and Hodgkin's disease, or malignant lymphoma, are most familiar terms; Dupuytren's contraction is a peculiar disease of the palmar fascia, and Raymond's disease is otherwise known as "local asphyxia, local syncope, and symmetrical gangrene." The dentists have Rigg's disease and Fauchard's disease.

The saints, and the gods of the pagans have had their share also in medical nomenclature—of this, St. Anthony's fire, St. Guy's and St. Vitus' dance, the sacred disease of Hippocrates (epilepsy), and the ignis sacer, or anthrax, are illustrations.

News of the Week.

Professor Berger, of Breslau, well known as a neurologist, is dead.

Professor Ch. Seby, who had recently been called to the Chair of Anatomy at Prague, is dead.

The Medical Society of Virginia holds its next annual meeting at Alleghany Springs, beginning September 15th.

In the Congo Free State are 4,500,000 people and only half a dozen doctors; at least so accounts state.

Ferrán's Charges for Preventive Inoculation.—If, as seems likely, Ferrán is not to acquire fame through his so-called preventive inoculation of cholera, he appears to have had a good thing pecuniarily. The charge for each vaccination is said to have been about $2.50, and for several weeks in succession he and his assistants inoculated an average of six hundred individuals a day.

The Epidemic of Small-pox in Montreal is assuming alarming proportions. It is reported that there are over fifteen hundred cases now in the city. The sanitary service, never very efficient, is inadequate to the demands made upon it now.

An Operation for Cancer of the Stomach.—The daily papers of the 1st inst. contained full accounts (with office address of the surgeon) of an operation performed at Charity Hospital for removal of an abdominal cancer.

Cultivating Coca.—The coca plant, from which the new local anæsthetic is obtained, is being planted on a considerable scale at Ceylon.

Typhoid Fever in a Lunatic Asylum.—Typhoid fever has been prevalent in the New Jersey State Insane Asylum at Morris Plains, sixteen cases having already occurred. A careful examination of the premises and buildings resulted in the conclusion that the prevalence of this disease was caused by the imperfect drainage system. On one side the sewage is run into trenches within four hundred feet of the building, and is then allowed to deodorize in the air, and the gases are carried into the rooms of the patients.

New Fields for Medical Practice.—Our editorial of some weeks ago, in which we called attention to the possible advantages of certain foreign countries as fields for medical practice, has excited an unexpected amount of interest. We have received a number of letters from different physicians asking for further particulars. We cannot attempt to give them. Stanley's book on the Congo contains trustworthy information regarding that subject, though perhaps the views are a little rose-colored. Information regarding Mexico and the Argentine Republic can doubtless be got through the State Department and the consuls of those countries.

Dr. Partington, after reading of the wholesale withdrawals from the International Medical Congress as at present governed, was heard to remark sententiously, that he feared the Congress was likely to be merely a sexual one.—*Boston Medical and Surgical Journal.*

The Third Annual Meeting of the American Rhinological Association will be held at Lexington, Ky., October 6, 1885.

A Spurious Hermaphrodite.—A curious case, reported in the *Gazzetta degli Ospitali*, July 29, 1885, has recently come before the Italian courts of a supposed woman who was found to be a man. The case furnishes an instance also of poetic justice. The individual, who is now fifty-one years of age, was supposed at birth to be a female, and received the name of Faustina. Brought up as a girl, no suspicion was entertained of her sex, although at puberty the breasts were not developed and the beard began to grow. At the age of twenty-one she was married, but sexual intercourse was impossible, and after ten long years of ineffectual efforts the husband became discouraged, and the couple separated. Faustina had in the meanwhile discovered her powers, and had formed a secret attachment with a female acquaintance. After the separation from her husband Faustina went to live with a married brother. But they did not agree well together, and finally, after having come to blows, the brother turned Faustina out of the house. Fearing an arrest for assault, he thought to gain an advantage by accusing his pretended sister of having seduced his wife. The case was thus brought into the court, and Dr. Badaloni was called in to examine the defendant. He found that the case was one of complete hypospadias simply, and that the subject was unquestionably a man. The brother, however, not only lost his case, but was compelled to share his inheritance with Faustina, who had been excluded from it by law on account of his supposed sex.

Errata in Dosage.—Dr. A. F. Fuchs, of Fredonia, Wis., writes: "Your Vienna correspondent, in writing about Nothnagel and his mode of administering powdered digitalis, uses the proper numerals, but the improper words in expressing the dose. Three grammes (3.0) are equal to forty-five grains, and are not written .03 or .3, but thus, 3.0. In his article your correspondent is incorrect in every instance in which he uses the word gramme, excepting as regards salicylate and benzoate of soda. As most, but not all, of your readers know, centigramme is the term which should have been used. As a complementary means, one to three grammes of caffein would be very satisfactory to the undertaker. Centigrammes or decigrammes might benefit the patient."

Dr. Sands has not Resigned.—We are requested to state that Dr. Sands has not yet resigned his professorship, but will deliver his didactic course next winter as usual.

Defending Anti-cholera Inoculations.—Dr. Cameron has written an able plea in the *Nineteenth Century* in favor of Ferrán's anti-cholera inoculations. He claims that there is some evidence to show that one attack of cholera gives some immunity against another. Gebert is the only authority who has maintained this view.

Use of Bovine Lymph in Europe.—Bovine lymph is to be permanently introduced in place of human lymph in Saxony, during the course of the present year.

Changes in the European Universities.—A number of changes and new appointments have recently been made in the medical faculties of the European universities. Some of these we have already mentioned. Dr. Josef Reinsberg has been appointed Extraordinary Professor of Forensic Medicine (to lecture in Bohemian) in the University of Prague. Dr. Anton Wölfler has been made Extraordinary Professor of Surgery, Dr. Mauthner of Medical Chemistry, Dr. Hofniski of General Surgery, and Dr. Ultzmann of Urology, at Vienna. Professor Merkel, of Königsberg, succeeds to the Chair of Anatomy of the late Professor Henle, at Göttingen.

The Treatment of Mastitis by Rest and Compression.—Dr. Paul F. Mundé, of this city, writes: "The letter by Dr. P. A. Harris, in your issue of August 22d, on the 'Treatment of Mastitis by Rest and Compression,' in which, among other things, he claims the priority of that method over Dr. W. F. Milroy, late house-surgeon to Maternity Hospital, New York, begins by a very evident insinuation that, because the date of my acceptance of his (Dr. Harris') article for the *Journal of Obstetrics* is but a few days in advance of the treatment by a similar method of Dr. Milroy's first case, I being then on duty at Maternity as visiting-surgeon, Dr. Milroy must have received the incentive to the method from me, therefore from Dr. Harris. Now, as regards the question of priority between Drs. Harris and Milroy, there can be no doubt that it belongs to Dr. Harris, without the slightest fear of dispute. But perhaps Dr. Milroy may have independently hit upon the same or a similar practice, and the object of this letter is to show that he undoubtedly did so, and to refute the insinuation that he received his inspiration second-hand from Dr. Harris through me. In the first place, I have no recollection of having mentioned the subject of the treatment of mastitis by any method to Dr. Milroy, either at Maternity or elsewhere. Secondly, my other occupations and the distance to Blackwell's Island have for several years prevented my attending to my duties at Maternity with the regularity required by the rules (for which reason I resigned the position last June); and hence I find by the visiting-book, which I have taken pains to have consulted on the matter, that I visited the Maternity only twice during April, once during May (15th), and not at all during June, 1884, although technically on duty. I could not, therefore, have communicated Dr. Harris' method to Dr. Milroy. At some time during the past spring, Dr. Milroy wrote me from Chicago, asking permission to publish the cases of mastitis treated by him on my service by his method, a permission which I cheerfully accorded him. This is all the connection I had with the matter. Justice to Dr. Milroy, as well as in a minor degree to myself, would seem to call for the above statement."

London as a Great Medical Centre.—Dr. Wesley M. Carpenter, of this city, in a letter to the British Medical Association, calls attention to the opportunities which London possesses for becoming a great centre for advanced medical teaching. These consist in the great abundance of clinical material which so large a city must afford, the existence of a prosperous and wealthy corporation, the British Medical Association, which might take the matter in hand, and the fact that the Royal College of Surgeons has recently received an enormous sum of money which might well be used for purposes of advanced medical teaching. One thing is certain, that, if London does not do something, New York will. Already it is ahead in the matter of special and post-graduate instruction.

Afraid of Ferrán.—Ferrán and his "caldos" are now viewed with dread and terror by all the towns where the Government ordered him to follow up his "preventive cholera inoculations;" so much so that, as soon as it became known he was to visit certain towns, the people rose with the Alcalde and Municipality, and prevented him from entering the towns. So it happened in Denia, which was to be his "centre;" also in San Matero, Oliva, etc.—Cor. *British Medical Journal.*

Fatal Poisoning by Morphine Through a Druggist's Mistake.—A druggist of Hoboken, Mr. Am Ende, well known in this city as a conscientious and enterprising man, put up ten grains of morphine in powders, instead of quinine as prescribed. The powders were taken by two young ladies of Hoboken, and both died from morphine poisoning. Thereupon Mr. Am Ende took a poisonous dose of atropine. The incident bears its own moral: That the most careful can sometimes make the most serious mistakes. There is room for the broadest charity for Mr. Am Ende, as there is for the sincerest sympathy for the afflicted family.

Dr. Frank B. Gallery, one of the prominent physicians of Rochester, died, on August 29th, from the effects of an operation recently performed on him. He was incapacitated from professional duty some time ago, and removed to the town of Greece, where he died. He was thirty-eight years of age.

The Next Annual Meeting of the American Public Health Association will be held at Washington, D. C., during the second week in December. Dr. Smith Townsend, the health officer of the District, is chairman of the committee of arrangements, and has already appointed his subordinate committees.

INTERNATIONAL MEDICAL CONGRESS MUDDLE.

The following correspondence, sent to The Medical Record, will speak for itself:

Baltimore, August 31, 1885.

Apropos of the meeting of the Committee of Arrangements in New York this week, I enclose you a choice and unique bit of literature on the subject of the International Congress, in the shape of a circular and blank endorsement, sent to the profession here by our worthy representative, Dr. John J. Lynch. The circular takes a view of the defection from the new organization somewhat different from the *Journal of the American Medical Association;* for while that publication asserts, in its editorials, that the opposition is made up of a few discontented men, Dr. Lynch complains of the many who have resigned positions even in Baltimore. The endorsement is a cringing effort to secure allegiance to the fast-waning power of a totally unworthy and unpopular organization. Together with a copy of the circular and endorsement sent me, I enclose you a copy of my answer to Dr. Lynch, which, if you see fit, I should be glad to have you publish.

Very truly yours,
John Van Bibber, M.D.

47 Franklin Street, Baltimore, Md.

(Copy of Circular.)

Baltimore, August 15, 1885.

My Dear Doctor: The resignation of many of the gentlemen in this city who were given positions on the various sections, etc., of the Ninth International Congress, to be held at Washington in 1887, by the Committee of Arrangements, which met at Chicago in June last, renders it necessary that I should be prepared to suggest names to fill these vacancies at the approaching meeting of the Committee in New York, September 3d, proximo. To do this I must know who approve of the action of that Committee and are prepared to lend their names and efforts to make the Congress a success, and who are not.

I beg, therefore, that you will sign the enclosed endorsement if you are prepared to support the action of the American Medical Association and its Committee, and return it to me by mail at your very earliest convenience. Very respectfully, etc.,

John J. Lynch, M.D.

1 S. Broadway, Baltimore, Md.

(Copy of Endorsement.)

The action of the American Medical Association, at its meeting in New Orleans in April and May, 1885, and the subsequent action of its Committee at Chicago, in insisting that only those who support the National Code of Ethics should become members of the Ninth International Medical Congress, to be held in Washington, D. C., in 1887, meets my hearty approval, and I will do all in my power to promote the success of the Congress.

——— ———, M.D.

(Copy.)

West End, August 29, 1885.

Dr. John J. Lynch, Baltimore:

My Dear Sir: I beg leave to return to you the enclosed endorsement unsigned, and I take great pleasure in explaining my action to you. I do not consider that the New and Old Code controversy, which is a local one in New York, has any bearing whatever on the question of an International Medical Congress. In consequence of the "resignation of many of the gentlemen of this city who were given positions on the various sections, etc., by the Committee of Arrangements which met in Chicago in June last," I do not consider that you or your decimated committees represent the medical profession of Baltimore any more than Dr. Shoemaker and his associates represent the city of Philadelphia. The extent to which this simile may be carried must be a mortifying truth, not only to you, but to every member of the present Committee of Arrangements.

The fact that the most prominent members of the profession, in all the medical centres of the United States, have withdrawn from your organization cannot be considered a very high compliment in this country, but when this action is advertised, discussed, and criticised among the foreign members of the International Congress, your position becomes unenviable in the extreme.

As a member of the Section of Neurology and Psychiatry under the organization of Dr. Billings and his associates, my position was very clearly defined, and, under the circumstances which I have pointed out to you, I hope you will pardon me for not wishing to change my associations.

Although we live in the same city, I have, by some strange misfortune, been deprived of the pleasure of knowing you personally, yet believe me, my dear doctor, that in your present trying and mortifying position you have my most sincere sympathy. Very truly yours,

John Van Bibber, M.D.

The following propositions are also offered from another source for consideration:

Two committees have been formed in relation to the International Medical Congress—which is legitimate?

It should be remembered:

1. That the American Medical Association Committee was invitatory as well as executory.

2. That the International Medical Congress accepted the invitation of this committee, and by resolution ordered it to make all the arrangements for the meeting in this country in 1887, by virtue of its inherent power under its constitution.

3. It follows that this committee became the organ of the Congress, and it was instructed to execute *its* will at its meeting in this country.

4. That this committee of eight had no existence, so far as the Congress is concerned, until the Congress created it.

5. That when formed it became the organ of the Congress, its controlling body in this country, to carry out its objects.

6. That so far as the Congress is concerned, this committee of eight was only one of invitation, and could hold no power from the American Medical Association to act for the International Medical Congress, a superior organization, created for scientific purposes, and without local politics.

7. That as a committee of the American Medical Association it was the duty of the committee of eight to report the result of its action to the body which created it, which having been done, it ceased to exist as an agent of the American Medical Association, because its creator has no power to act, as an association, for the Congress.

8. That the new committee of twenty-eight, added to the eight original members, does not exist, as the American Medical Association has no power to create such for the International Medical Congress.

9. That the committee of eight can resign as appointees of the Congress, *only*, by the consent of that body or its executive committee, and that it is still amenable to the Congress as its agent, and it is its duty to act as its representative and ignore the action of the American Medical Association entirely.

The appointees of the committee of eight still stand good.

Reports of Societies.

British Medical Association.

FIFTY-THIRD ANNUAL MEETING.

Held at Cardiff, on Tuesday, Wednesday, Thursday, and Friday, July 28, 29, 30, *and* 31, 1885.

REPORTS OF SECTIONS.

(Continued from page 248.)

SECTION OF MEDICINE.

WEDNESDAY, JULY 29TH—FIRST DAY.

DR. WILKS in the Chair.

In opening the Section DR. WILKS, as its President, read an address on

SOME CAUSES OF DISEASE AND ON SOME REPARATIVE AND DESTRUCTIVE PROCESSES.

He acknowledged himself as to some extent out of harmony with certain prevailing notions, and was, in spite of many inducements to change, still disposed to abide by doctrines which he had been endeavoring to promote for the last thirty years. He then proceeded to dwell upon the difficulties of distinguishing between processes which are reparative and those which are only destructive, and gave interesting illustrations, from both a physiological and a pathological point of view.

DR. CUMING moved a vote of thanks to the President for his address, which was seconded by DR. W. ROBERTS, and carried by acclamation.

THE PRESIDENT acknowledged the compliment and immediately called upon the Section to proceed with the debate

ON THE TREATMENT OF RHEUMATISM.

DR. BRISTOWE opened this debate, according to programme. He said, when first asked to do so, he thought the subject had been fairly threshed out, but on further consideration he felt that the disease was so common that it was worth the while of practical men again to compare notes. He supposed, as he knew there was an impression abroad that he was very sceptical as to the use of drugs, an impression which he admitted was perhaps deserved, that it might be intended to extract from him some admission as to an acquisition of further power over the disease. He confessed, however, that he had nothing new to communicate. He had seen no mode of dealing with acute rheumatism, and he had no manner of faith in any power of controlling it by drugs—at any rate until the last few years. He had used, as at one time so popular, nitrate and bicarbonate of potass, but he had not been impressed with the possibility of this method being curative. Then he had used blistering, after the plan of Dr. Herbert Davies, and his experience of this treatment impressed him with the belief that it did benefit the joints, but did not curtail the inflammation of those joints. Next he had tried a formula propounded by Dr. Peacock, and for some years a favorite one at St. Thomas'. It contained several drugs, including iodides, bicarbonates, colchicum, etc. He supposed this might act after the manner of a blunderbuss loaded with a variety of shot, and if a patient had a little gout in his constitution, or a little syphilis, the doses might do him a little good in such respect. He confessed, however, that he had never seen this treatment influence the progress of a case of acute rheumatism. Then came the salicylates, and in adopting them he perhaps did so without any enthusiasm. In fact he lagged behind, as he generally does, with regard to new remedies. He is content to wait while a good deal of evidence accumulates, and then, of course, as a teacher, feels bound to try them. So here he waited, he lagged behind, but there is this he must say, that having eventually begun to use these salicylates he has not given them up, and this he cannot say of any other drugs.

In regard to his conclusion, 'perhaps he still lagged behind many more enthusiastic physicians who regarded the salicylates as specifics for rheumatism as much as quinine is for ague, or iodides and mercurials for syphilis. As to statistics, we ought to remember that in comparing them the items or integers are unequal, and with every effort to equalize them we cannot obtain perfect mathematical solutions to clinical problems. He found, however, that salicylate of soda or salicylic acid reduced the temperature in two or three days to normal. As the temperature falls the pain abates, but the affection of the joint lags behind. This, however, he considered only natural. What could be expected? A damage had been done—more or less effusion had been poured out—and time was required to repair the injury. Dr. Bristowe next turned to the cardiac lesions. Does the tendency to heart disease disappear? he asked. There was, he said, much difficulty in answering this question, and the remark he had made as to statistics must be applied here. He held in his hand the statistics compiled from his hospital case-books, but would not read them, as that would be tedious [applause], and they would appear in due course in the *Journal*. He would, however, state that they were highly favorable to the treatment. It had been said that relapses are not prevented, and some said they were more frequent after salicylates. He knew that relapses did occur, but not more than we find in other diseases after what we call specific treatment. He thought the relapses were possibly not more than those of ague after quinine, syphilis after mercury and iodine, or psoriasis after arsenic. In these diseases, especially the last, the drug is continued after the tendency to recur is apparently gone, but they do recur after this, and, moreover, when the system is, so to say, saturated with the drug, which should prevent relapse. Then in rheumatism there is a natural tendency to remit the salicylates. With the fallen temperature the patient feels so much better that he thinks he ought not to take more medicine. He wants to get up and leave the hospital, and the medicine is often remitted too soon, and relapses ensue; noises in the ears, deafness, delirium, and some other temporary ills might occur, but he had never known any real danger or had any cause for anxiety. As soon as convalescence was fairly established he fed his patients up. As to the nature of rheumatism and the influence of the drug over it, there were indications that it might be analogous to malaria, and Dr. Maclagan's work showed that there was much to be said for this view, which was in reality the one that led Dr. Maclagan to the discovery of the value of salicylates. Before closing his remarks he wished to add that he had this week had two cases in St. Thomas' over which salicylate of soda had no influence, but this might be attributed, he thought, to the fact that they were perhaps not really cases of true rheumatic fever. In one the inflammation was confined to one knee, and he was now inclined to regard the case as one of synovitis only. The other was a case of hyperpyrexia, which proved speedily fatal.

DR. SIDNEY COUPLAND said he had no doubt that the salicylates afforded us the best remedy, but he felt it was too much to call them specific, for they had no effect whatever on the cardiac part of the disease, by far the most important part. They reduce the fever and ease the pain, and this to such an extent that we now need seldom give opium. He gave smaller doses now than in his early cases, but he did not discontinue the medicine for a week or more after all symptoms had disappeared. The doses might be reduced, but the drug ought not to be omitted. He felt sure relapses were due to early getting up, the exposure thereby occurring, and to the solid food, which was permitted too early. In some cases of failure he had observed that there was a suspicion of gonorrhœa having lately occurred, and the salicylates were powerless in gonorrhœal rheumatism. He thought, too, he had noticed other diseases of the genito-urinary tract complicating obstinate cases, and he

suggested it might be well to inquire how far inflammation of this membrane, however arising, might be associated with rheumatic attacks.

Professor Latham said he had no belief whatever in germs as the cause of rheumatism. If the disease were produced by microbes, how was it cured, as it used to be, by bleeding? Did the blood drawn reduce the number of organisms? and were we to conclude that a certain number of microbes produced rheumatism, but a few less were of no consequence? So purgatives, once in general use, would cure the disease. Did the evacuations carry away a few of the extra bacteria and leave their friends so reduced in numbers as to be powerless for harm?

Again, did opium put the bacteria to sleep? If we cut across the spinal cord we at once get excessively high temperature, but it is not held, surely, that the operation instantly develops swarms of bacteria which give rise immediately to hyperpyrexia. What was rheumatism? Why do we see from the same causes pleurisy, pneumonia, catarrhs, rheumatism, and other diseases. Could it be held that all are due to germs or organisms always surrounding us? The fact was, he felt that this doctrine of bacteria had been carried too far. The old lactic-acid theory was much nearer the truth—indeed, very near it, as he had shown in recent publications. Cold applied to the surface modifies the circulation and therefore the nutrition of muscular tissue. What, then, is the relation of muscle? what that of albumen to lactic acid? The chill affects the nutrition and the successive changes in which cyan-alcohol, glycocine, lactic acid, and uric acid appear are interfered with. By giving purgatives, very little animal food, and saturating the system with salicylic acid, not stopping short of producing toxic symptoms, we could inaugurate a new series of changes. Lactic acid had much to do with the disease but was not the body on which salicylic acid directly acted. Rather it was excessive formation of glycocine and uric acid in the tissues that set up the symptoms, while the salicylic acid cured by combining with their antecedents and so preventing their formation. He had endeavored to show that albumen is a compound of cyan-alcohols with a benzene nucleus. The cyan-alcohols had been prepared in the laboratory except the lowest of the series, $CH_2\begin{cases}OH\\CN,\end{cases}$ which requires for its preparation formic, or methylic aldehyde, but this has not yet been isolated. From cyan-alcohols corresponding amido bodies had been combined. Therefore we might expect that by treating $CH_2\begin{cases}OH\\CN\end{cases}$ with NH_3 we should get a cyanamide $CH_2\begin{cases}NH_2\\CN.\end{cases}$ This last, when hydrated, would form amido-acid glycocine. From the same cyan-alcohol attached to a benzene nucleus he held creatine to be formed, and by further changes, urea and the next cyan-alcohol higher in the series, $CH_3.CH_2\begin{cases}OH\\CN.\end{cases}$ Then by hydration of this, as well as $CH_3.CH\begin{cases}OH\\CN,\end{cases}$ lactic acid would be formed. Again, the same antecedent $CH_2\begin{cases}OH\\CN\end{cases}$ might combine with salicylic acid in the liver. There, if combined with cholic acid we might have glycocholic acid formed, which by alkalies is converted into cholic acid and glycocine.

$$CH_2\begin{cases}OH\\CN\end{cases} + C_{24}H_{40}O_5 = C_{26}H_{43}NO_6.$$

Methene cyan-alcohol. Cholic acid. Glycocholic Acid.

Now, if salicylic acid combined with the methene cyan-alcohol we should have a formula of the same character as is held to be represented by the molecules of living albumen,

$$CH_2\begin{cases}OH\\CN\end{cases} + C_6H_4\begin{cases}OH\\COOH\end{cases} = CH_2\begin{cases}OH\\CN.OH\\COOH.\end{cases}$$

As it combined CNOH would become CONH, and the salicylic acid would be converted into salicyluric acid. Amid some manifestations of impatience Dr. Latham, who had provided no diagrams to assist in following his formulæ, concluded by saying that salicylic acid might prevent the formation of glycocholic acid, and consequently of glycocine, and thus prevent the formation of uric acid and lactic acid. His views would be published in extenso.

Dr. Prosser James said he would not attempt to follow Professor Latham's interesting views, which required study at leisure, but begged to recall the attention of the Section to the subject announced for the debate, which was the treatment [applause] of acute rheumatism. He had, he said, too much reason to feel the scepticism attributed to and confessed by the opener of the debate, Dr. Bristowe, but he was not altogether devoid of faith in drugs, and had himself derived from them very great relief.

Dr. James said he had had a very painful personal experience of various methods of treating acute rheumatism, for he had had several severe attacks, and as a sequel he now suffered from osteo-arthritis. Some authorities, indeed, held there was no connection between the acute and chronic diseases mentioned. His own case pointed in the other direction. No question as to the diagnosis could arise. He had the happiness of numbering among his friends the survivors of his former teachers, most of his colleagues, and many other eminent physicians, whose sympathy and desire to help had been as welcome, and perhaps as effectual, as their advice. They were of one opinion as to the nature of the early attacks. Since the chronic disease succeeded he had also experienced the usual relapses. He had been under treatment by alkalies, by salines, by opiates, by quinine, by the salicyl compounds, by blistering, by rest in bed *without* peppermint-water, and so on, and would just state his experience of some of the remedies. As to nitrate of potash and other salines, he had been unable to satisfy himself that these drugs exercised any influence over the progress or duration of the disease, and the same remark applied to some other modes of treatment which had been advocated.

Passing to treatment which gave him relief, he spoke first of opium, and commended small doses of morphia—preferably by subcutaneous injections. Only just enough to numb the pain—to render it, as it might be said, bearable—should be given, and then it could be continued for some time, if required, without any need for increasing the dose. It was not necessary to narcotize the patient. When the pain abated, sleep often ensued. Small doses did not disturb the functions, nor create a desire for repetition, but they exercised a most soothing influence over the nervous system which reduced the intense agony to a more endurable pain.

Dr. James next spoke of alkalies. In his first attack, which occurred at the time when the alkaline method was most in favor, the treatment was begun with alkalies, administered so as to speedily render the urine neutral. This neutrality was maintained for several days. As no effect was produced on the disease, no relief to pain or any other symptom, opiates were given, and the amount of alkalies reduced. Speedy return of excessive acidity and some increase of fever induced his advisers to urge fuller alkaline treatment. This was accordingly pushed to what was deemed the limit of safety, after which small doses were given from time to time on the appearance of excess of uric acid or urates. The impression produced was just that which he had always entertained—that alkalies were most useful at the commencement of an attack, that they should not be pressed beyond the point of neutralizing the urine, that the neutrality might be maintained with advantage for a day or two, and that then alkalies had accomplished all they could do, except as occasional correctives. Employed in this way he had no fear of their producing anæmia or debility. Even in chronic rheumatism small doses of alkalies at intervals

may be called for to correct digestion or for other purposes. Perhaps the best alkali for the purpose was lithia, the dose being small and the solubility of its salts great.

The late Dr. Billing taught that rheumatism is a neurosis and should be treated by quinine, and watched with much interest the effect in his (Dr. J.'s) case, as he had himself suffered in the same way and derived great benefit from quinine. A continual state of cinchonism was maintained for weeks, a consumption of twenty-seven grains daily being required for this. The antipyretic effects of the remedy were distinct and unvarying. Lessening of this dose was always followed by an increase of temperature and of the rapidity of pulse.

As the disease abated the dose could be lessened without so marked an increase of pyrexia, but until convalescence set in, every diminution was followed by a rise in the pulse and the thermometer, so that an accidental omission of a pill would leave its record on the charts. Certainly the remedy pushed to a moderate degree of cinchonism had afforded him material and constant relief, and had given rise to no material or important inconvenience.

In a subsequent attack salicin was tried. Its effect resembled that of quinine, but was much less marked. It seemed adapted only for acute attacks, and should be used at the outset and pushed in large doses. In the chronic cases it seemed almost useless. But in one severe exacerbation or intercurrent attack it had afforded him some relief, checking pulse, temperature, and pain; but it had to be taken in fifteen- or twenty-grain doses every two hours to secure this, and once in thirty-grain doses. The safety, the even tonic influence, of these doses gave it the preference to the other salicyl compounds. Noises in the ear and other symptoms, such as we see in mild cinchonism, soon come on under large doses of salicin. Constipation, too, he found apt to occur, and requiring to be corrected.

He regarded salicin as superior to the other salicyls, as he had never known it give rise to dangerous symptoms. He thought its effect more similar to that of quinine. It was tolerated by the stomach when the other salicyls were rejected. He had used it ever since its reintroduction, for, as he had shown elsewhere, it had long ago been employed, but long fell into disuse. In fact, the willow was a popular remedy from early ages. The Greeks employed it, and more than a century ago it was treated of as a febrifuge and as what we should now call an antipyretic. Salicin was an early substitute for quinine, but the larger doses required rendered it more costly, for which reason probably it was too soon laid aside.

Dr. W. R. Thomas said we were too much influenced by fashion. He had not found salicin a grand remedy in all cases. We ought to select our cases. He had been accustomed to reckon three varieties of rheumatism, viz., sthenic, asthenic, and gonorrhœal. In the sthenic form he relied on carbonate of potash. In the asthenic cases he would trust to salicin, and after this discussion to quinine. The third form required different treatment.

Dr. Markham Skerritt said there were two sides to the question of salicin; for while some cases improve at once, in others the disease would hold in spite of salicylate of sodium, which was the salt he usually preferred. The more acute the case, the higher the initial temperature, the better was the salicylate of sodium. In subacute cases it was of much less use. He lessened his doses as the disease gave way, but he went on with the salt until the temperature had been normal for a few days, and then he gave iron, selecting the most astringent preparation which the patients could tolerate.

Dr. Pavy had not intended to speak, but the interest of the debate induced him to add his opinion of salicylates. He found the more acute the disease, the more generally it was distributed; the greater the number of joints involved, the more likely was salicylate of soda, which he most used, to serve. But it has not the influence over complications that it has on the disease. It could not cut short either endocarditis or pericarditis; it was not a remedy for complications. The temperature and pain were soon relieved, but we must then go on with the remedy for twelve or fourteen days, or relapse would very likely occur. The effect only controlled the disease; it did not cure.

Dr. Harker insisted on the value of the clinical thermometer. He had found salicin and quinine most useful, and could endorse what a previous speaker had said in regard to these most important antipyretics.

The President, in closing the debate, said all seemed satisfied that we had a new remedy of late years. No one had seen a case cured in twenty-four hours before salicin was used; but relapses seem to occur oftener, and so our cases go on again. His clerk at Guy's had collected the records of hundreds of cases, and found that, on the whole, patients seemed to remain in hospital about the same time as formerly.

At the conclusion of the debate on rheumatism the papers were proceeded with.

Dr. L. D. Bulkley, of New York, read a paper on

ASTHMA, AS RELATED TO DISEASES OF THE SKIN,

in which he gave statistics of his hospital practice, showing how often asthma had occurred in a patient suffering from various forms of cutaneous disease.

Dr. Byron Bramwell warmly thanked Dr. Bulkley for coming so far to state his experience, and briefly stated the gist of a paper he had down upon endocarditis, and promised a demonstration for the next morning.

Mr. C. R. Straton read a paper on "Chorea," giving an account of his views on this disease during what he termed its pre-choreic stage.

The time having expired, and a garden party being arranged, to be followed by a conversazione, a number of other papers were taken as read, and the Section adjourned.

Thursday, July 30th—Second Day.

From ten to eleven o'clock in the morning Dr. Bramwell gave a series of demonstrations on "Ulcerative Endocarditis," and at half past eleven Dr. Pavy gave demonstrations on the "Clinical Examination."

At two o'clock in the afternoon The President took the chair, and at once called upon Dr. Pavy to open the discussion which had been arranged on the clinical aspects of glycosuria. Thereupon Dr. Pavy proceeded to read a long paper, occupying a full hour in the reading. He found the disease most common between the ages of forty and sixty years. It was more common in persons of Jewish race than among Christians, and, also, it was more amenable to treatment. It was often very insidious in its approach, but sometimes it would set in very suddenly. He had known cases in which no suspicion had been entertained of unsound health for a considerable time after the disease commenced, and he had been able to prove this. Persons who wear black-cloth trousers, such as clergymen, sometimes remark the difficulty of brushing out certain white spots, and he had heard it stated that the porters in French hotels could recognize patients with glycosuria by the extra trouble of brushing their clothes. In micturating against a wall some of the urine was splashed on the trousers, and on drying the sugar was left forming the white spots in question. He had remarked that many of these patients display an intense congestion of the membrane of the mouth and throat, and he had come to consider this as a marked sign of glycosuria. The disease might endure for years. This was oftenest the case in elderly persons, but it might happen also in the young. Sometimes it disappeared entirely. He did not mean it was kept under control, but that it was eradicated. Sometimes sugar appeared, but only temporarily; then the red condition of the

mouth was important. He saw a case with this, and on testing the urine found sugar, but though often tested for afterward, there was none. Diabetes insipidus and mellitus might coexist. The quantity of urine was in such cases without any definite proportion to the amount of sugar. Some patients perspired on one side only, and this, he thought, showed that the state of the skin was associated with the condition of the nervous system. Diabetes occurred in association with enlargement of the liver, and such patients might go on for years with no other ill-effects. Perhaps the enlargement might be considered compensatory. Neurotic conditions, especially spinal, coexisted with glycosuria.

Sometimes ataxia came on first, sometimes diabetes, and so we might feel sure they are associated. Patients would say they had sciatica or gout. Others that they could not feel properly in their legs. One told him that he felt as if he had got a twenty-pound weight on his feet, another as if his boots were too large. Darting or lightning pains were also complained of. There was increased sensation of the skin, the hyperæsthesia being shown by pinching. In other cases the pain was deeper and said to be felt in the bones. He had known a seam in the dress complained of as causing pain so as to prevent the patient lying down. The pains were worse at night, so often that there seemed a direct connection between the time and the symptom. Sometimes the pains attacked the arms instead of the legs. Exophthalmic goitre and glycosuria often occurred together. As to acetonæmia, he did not believe in it. Of course he knew that diabetics might die comatose, and this was sometimes called "Kussmaul's coma." He did not know why, ever since 1874, it should be so called; for our countryman, Dr. Prout, had long before described it. Whatever greatly affects the patient may bring on this complication. Grief, distress, fatigue, and other causes would do so. He had seen the first indication of its approach in his consulting-room, when the patient had come a journey and was naturally anxious, and in a day or two he was dead. Vomiting would also bring on the coma, which he attributed to exhaustion of the nerve-centres. Rapid pulse and breathlessness were suspicious symptoms. The patient might complain that he could not get air enough. A little later drowsiness would come on, and the end was near. Fatty emboli had been much spoken of; they were purely physiological, as he had long ago shown in his lectures on physiology, and fully accounted for by the food. Albuminuria sometimes coexisted. In small amount this was not of much consequence, but sometimes it passed into Bright's disease.

Dr. Skerritt read the report of a case of febrile glycosuria of an acute kind, and he said he had found that febrile attacks diminished the amount of both the sugar and the water. Sometimes when febrile diseases exist, sugar would entirely disappear. Again, glycosuria might set in quite suddenly, as if it had been set up by the febrile disorder.

Professor Latham commented on the association between diabetes, gout, and rheumatism, and said that the condition of the nervous system might set up either of the three. In gout there was less irritability of the sympathetic, corresponding with the advancing years, in which the disease is most observed, and so we get glycocine. But in the sensitiveness of youth the oxidation did not go so far, and so we had rheumatism. If oxidized less diabetes ensued, which he regarded as the analogue of muscular rheumatism, while acetone was the analogue of hyperpyrexia.

Dr. W. R. Thomas maintained that the first consideration was diet, as inattention to this had first brought on the disease. In patients of full habit diet was most urgent, and yet they were most difficult to manage. The results of experiments confirmed this view. When syrup was injected into a rabbit's stomach after a meal it was not quickly absorbed into the system, but retained by the large quantity of vegetable matter, which did not give it up so rapidly as to incommode the liver. But when the same experiment was made on dogs, the sugar was rapidly absorbed—too rapidly for the liver to convert it into glycogen—and therefore glycosuria ensued. We should therefore give plenty of vegetable food, and at the same time alkalies. The neurotic variety of the disease was often seen in men of business who were greatly preoccupied and persons who worry. A sea-voyage then is a good thing, and he had known one case completely cured by it. Bromide of potassium should be given at night to produce sleep, arsenic regularly as a tonic, and opium occasionally to check the excessive excretion of sugar. Exercise should be taken to divert from the brain.

Dr. Savage was not able to be present, but he sent a note of apology, in which he stated that the insane did not often suffer from glycosuria, but that he had seen several cases in which there had been an alternation between the two diseases.

The President remarked that he did not believe that the coma was due to acetone. One speaker had said he did not believe in acetonæmia. Why, then, did he use the term? He protested against such a use of words. Kussmaul's name had also been used, and confessedly without reason; he would be glad to see all such names discarded; they were very inconvenient.

Dr. Pavy replied. He said he thought it was the liver, whose disordered function made the changes; but it was the nerves presiding over that function which caused the disease.

This closed the discussion, and the papers were then proceeded with.

Mr. Lockhart Stephens then related a case of simple stenosis of the œsophagus. A bougie encountered the obstruction at a distance of fifteen inches from the front teeth. The disease went on to a fatal termination, and on post-mortem examination the diagnosis was confirmed. The specimen was handed round, and the stenosis was seen to be of small extent, but to almost completely close the gullet, a glass rod about the size of a crow-quill being passed through.

Mr. Stephens also exhibited a specimen of congenital heart-disease and gave its history.

Dr. W. R. Thomas read a short paper on

THE INFLUENCE OF MALARIA ON THE PROGNOSIS OF OTHER DISEASES.

He had in Sheffield constant opportunities of observing that many diseased states were complicated by malaria, which was a frequent cause of anæmia and many other obscure maladies. In several diseases it would be found useless to treat merely by nourishing up the patient so long as he remained in a malarious district. If, however, the patient were sent to a high altitude, and at the same time were treated with quinine, a cure was not unfrequently rapidly brought about.

Dr. Wilks mentioned the case of a practitioner who used to give quinine in almost all cases of disease.

Dr. C. R. Drysdale read a paper

ON THE HYGIENIC TREATMENT OF PHTHISIS.

He said he had always believed in the unity of phthisis, and likened that disease in many ways with syphilis, so that the idea that it is a germ-produced disease seemed to him quite tenable, although not so clearly made out as Dr. Germain Sée would have the medical world believe. Whether, however, phthisis be a disease resembling syphilis or not, it is most fatal under all treatments, nor have we at the present moment any special remedy which exerts any marked influence on this malady, as we have in mercury and iodine in syphilis. Some thirty years ago consumption was believed by most men of experience to be quite incurable. A friend told him that Dr. Stokes used to say he had only had one case where the patient recovered from a well-marked attack of the disease. Modern physicians are far less despondent.

To take, for instance, the evidence of Dr. Austin Flint, we find that physician saying, at the Philadelphia Congress in 1876, that he had known of seventy-five examples of arrest of phthisis in a practice of thirty-eight years. All those who have of late years watched carefully their private cases of consumption, have been occasionally delighted to find that the disease is not necessarily so fatal as our predecessors thought. At the Worcester meeting he had heard of several eminent medical men who had themselves been consumptive, and had had a long arrest or cure of the disease. Such cures or arrest, too, took place under a variety of circumstances, and almost led to the view entertained by some, that the benefit derived from a change of climate in consumption is due not so much to climatic influence *per se*, as to the circumstances incidental to the change. Yet, in his experience, change of climate was by far the most important adjuvant in treatment. Long sea-voyages were excellent in many respects, and objectionable in others. The air on deck was pure and salubrious, but in the cabins far from wholesome. Sea-sickness was by no means uncommon among consumptive patients, and greatly added to their sufferings in rough weather. Life at sea was dull and monotonous; the society apt to be limited and unsuitable to the patients, and heart-burnings and squabbles might embitter his existence. Sailors, who were often so miserably lodged, when attacked with consumption, quickly succumb, and thus it was a mistake too often made, and of which he had sometimes been aware of too late, to send a patient, especially a lady, on a long sea-voyage. At the same time, when the ship was well appointed, and the berths roomy enough, a voyage to Christ Church, New Zealand and back, setting out from England in October and returning by Cape Horn in May next year, was a splendid feat in modern hygienic therapeutics, and sometimes arrests or cures the disease. There can be no doubt that various climates contain some of the requisites for the arrest of phthisis in varying degrees. These are absence from damp soil, asepticity of the air, and dryness and diathermancy of the atmosphere. Egypt, in the region of Cairo, was, on account of its dryness and warmth, an excellent winter resort for consumptives, who do not bear the cold well. The Riviera affords several agreeable winter resorts on the Mediterranean. Of these San Remo is commended by P. James; Dr. Hérard spoke most warmly of Algiers, which, he said, had arrested consumption in several able Parisian medical men. To those patients, however, who were not too much affected by cold weather, and who are in the first stage of phthisis, his experience, as well as theory, and the observation of many accurate observers (Weber, Denison, Williams), made him give the palm to residence in the Alpine districts of Europe or of the United States. The air was so pure in mountain valleys over four thousand feet in altitude in Switzerland, or a little higher in the Rocky Mountains, that, in the first place, the germs which caused putrefaction were absent, and the sun's rays were warm, even in January. If, then, the patient came to him in the early stage of the disease, before softening had taken place, he would send him at once to Davos, if in good enough circumstances, even in January. One gentleman this year went thither on January 2d, and returned wonderfully well in April. If the patient had to earn his own living—the lot of the vast mass of mankind—he advised him to go to Colorado, and, if possible, get some out-door employment in looking after cattle. This was very clearly curative in many instances. When these plans could not be carried out, we had still a resort to the Mediterranean shores, and a winter cruise in that sea for the well-to do. The workers should leave cities and work at out-door employments in the country. In this way a cure or arrest occasionally ensued. Life out-of-doors was obviously the best tonic in consumption, and cities are the hot-bed of the disease, which seemed rare in dwellers in mountain districts employed out-of-doors. The physician must not look on phthisis as incurable, but incite his patient hopefully to struggle for existence.

Dr. Wilks said that medical men were the best cases to inquire into as to the arrest of phthisis, and many students he had known with the disease had recovered and were now well.

Dr. C. R. Drysdale then read a paper on

THE TREATMENT OF SYPHILIS AND THE ALLEGED PREVENTION OF TERTIARIES.

The treatment of syphilis is still much disputed. In Paris and New York long, interrupted, continued courses of mercury are in vogue in all cases; in Edinburgh some treat all cases of syphilis without mercury: in London there is no clear rule laid down, and M. Diday treats some cases with, and some without, mercury. Whom shall we pin our faith to? By far the most important point in the treatment of the early stages of syphilis refers to the possibility of warding off the tertiary stage by the administration of courses of mercury. As a general rule, it may be said that any given case of primary or secondary syphilis may possibly come to the stage of tertiarism or gummy deposit. Diday asserts that when the early eruptions are light in color we may expect that tertiary symptoms will be absent; but in London and elsewhere this assertion has been adversely criticised, and the contrary opinion has even been put forward, *i.e.*, that slight syphilis at the outset is more apt to end in tertiaries than a copious eruption is. Few will now be found to endorse the opinion of the late Professor Hughes Bennett, that the chief cause of tertiary syphilis resides in over-dosing with mercury. Syphilis, of itself, it is now well known, is quite powerful enough to commit grave tertiary ravages. The very contradictory of that proposition, indeed, was maintained some years ago by M. Ricord at Birmingham, and has lately been restated by his eminent pupil, Dr. A. Fournier, of Paris. In a passage in *La France Médicale*, of May 23, 1874, M. Fournier thus speaks: "The chief cause of the passage of syphilis into the tertiary stage is doubtless the absence or insufficiency of treatment. . . . The consequences of expectation in syphilis are truly disastrous." Mercury, according to Fournier, acts on the poison, and ninety-five per cent. of well-treated cases under mercury will, he says, prove mild. Some English authors of repute, such as the late Mr. Solly, think that mercury given while the hard sore exists, may cause the disease alone. Mr. Henry Lee and Mr. Jonathan Hutchinson also speak in this way. Lancereaux again ("Traité de la Syphilis," 1873) denies that mercurial courses can ward off tertiarism, or the eruptive state, when given during the existence of the hard-sore. He puts it that it is bad enough for a patient to have syphilis without making of it a pretext of a treatment by mercury for years, since, after all, he says mercury is a very poisonous drug. A large number of syphilitics, he adds, get well without any remedy at all, and Lancereaux therefore concludes that mercury should only be given to treat eruptions, iritis, or other symptoms when present. Diet and regimen, which are so useful in other diseases, may be called in also to prevent relapses in syphilis. M. Mauriac, the able successor of M. Ricord at the Hôpital du Midi of Paris, holds the very same views as those cited from Lancereaux. Dr. Schumacher, junior, of Aix-la-Chapelle, sent me, a short time ago, an article of his on some recent experiments of M. Diday, of Lyons, on syphilis. These concern 74 cases of the disease treated by that gentleman between 1872 and 1882. Of these 49 were treated without mercury, and 25 with it. Diday concludes from these that mercury does not prevent the supervention of secondary symptoms, it does not seem to prevent the relapse of secondary eruptions. The disease is usually a mild one, and he seems to think the occurrence or non-occurrence of tertiaries is to be predicted by the severity of the case at its commencement.

Dr. Schumacher says that all cases which come to

Aix-la-Chapelle are grave syphilis, and therefore all require mercurial inunction for their cure. Dr. Edward Keyes, of New York (International Congress, 1876), is quite opposed to the view that mercury in small doses is injurious. On the contrary, Dr. Keyes holds that mercury is a tonic both to healthy and to syphilitic persons, and every case of syphilis should therefore be treated with long-continued courses of mercury, since prognosis is impossible. Mercury in small doses, he contended, increased the number of blood discs. He furthermore calls mercury an antidote to the poison of syphilis. Mercury is curative in all stages of syphilis, even in tertiaries, when iodide of potassium fails. Hence, Dr. Keyes gives mercury in small doses, as one-sixth of a grain of the green iodide, thrice daily, for three or four years; whilst Fournier leaves off the drug for a month at a time to resume it. The following propositions seem, in short, to be true, said Dr. Drysdale: The prognosis of syphilis is obscure. Mercury may be given in small doses without debilitating, and even in tertiary syphilis, now and then, in obstinate cases. Iodide of potassium is not of much use in early syphilis, but all-powerful in tertiaries. Mercury being a parasiticide is useful as a germicide in syphilis, but is rarely of much service in the tertiary period. Iodide of potassium is the sheet-anchor in tertiary disease, and should be given in doses of from five to twenty grains. It is not clearly proved that mercury given in the period of the hard-sore can ever prevent the appearance of secondary eruptions, alopecia, or iritis. Its chief use is to treat such symptoms when these are present. There is some evidence to prove that courses of mercury prevent tertiaries; but there is, on the other hand, much evidence against this view. Occasionally even tertiary symptoms are benefited by mercurial inunction, and in those where some affection of the nerves exists both iodide of potassium and inunction should be used. Finally, careful diet, climate, and other hygienic rules should be carried out in syphilis as well as in other chronic diseases, for the effect of time and régime is immense in all diseases where the system has been poisoned by some germ resembling that of syphilis; and above all, it must be borne in mind that experience has now shown us that syphilis at the present day is often a very mild disease.

Dr. Wilks asked Dr. Drysdale what his own actual treatment of syphilis was. He thought he had read some years ago that he had published cases of syphilis in infants which had recovered without any mercury.

Dr. C. R. Drysdale replied that at present he looked upon mercury as a parasiticide or germ-destroyer in the earlier stages of syphilis, and hence he had recently treated all his cases by small doses of mercury for periods up to a year or thereabouts, hoping thereby to prevent tertiaries. The cases mentioned by Dr. Wilks, of infantile syphilis treated successfully without mercury, were due to Mr. Allingham and Mr. R. W. Dunn. He himself had treated many cases of syphilis in adults without mercury, in most cases with good success, but in some tertiary symptoms supervened, and it was with the hope of, if possible, preventing these that he now gave small doses of mercury for a long time, like Dr. Keyes, of New York, and Dr. A. Fournier, of Paris.

Dr. Webster considered that the proper treatment of syphilis is the tonic treatment. He was in the habit of treating all his syphilitic patients with quinine, iron, and strychnia, and advising them to leave off all alcoholic drinks.

Dr. Payne, of London, said a large number of infants were treated with small doses of mercury for eruptions, which either were distinctly syphilitic or might possibly be so. The mercury never did any harm to the non-syphilitic cases, while it was extremely beneficial to the syphilitic ones. He would like dearly to get from Dr. Drysdale a clear definition of the term *tertiary;* and would also like to hear what is the cause of tertiary syphilis. Is it scrofula, or bad diet, or excesses, or what is it? In one case a young man with rupeal eruption did not improve in treatment as out-patient. He was taken into hospital and well fed, and rapidly got quite well.

Dr. Bulkley, of New York, thinks that syphilitic eruptions are better studied in skin-disease hospitals than anywhere else. He had abandoned the term tertiary, because the lesions which were supposed to belong to the late period of syphilis were occasionally seen early in the disease. He agreed with Dr. Drysdale that no one of any experience would endorse Professor Hughes Bennett's view, that tertiary syphilis was a product of syphilis and mercury, at least in modern times. When salivation was in vogue it might possibly have acted as a cause of that period. He agreed with Dr. Webster that patients with syphilis should neither drink alcohol nor use tobacco. His patients were quite debarred from the use of either. There was one point in the treatment of syphilis, and that was that it should not always be treated merely by mercury and iodide of potassium. The patient must be treated in every case. It is not necessary to give much mercury in the early stage of the disease; but if iritis occurs the dose should be raised, and iodide of potassium had occasionally its uses in the early period of the disease. He entirely agreed with Dr. Keyes' views as to long courses of small doses of mercury for two years or more daily. Dr. Drysdale had said that he was astonished at hearing from Dr. Henry, of New York, that some physicians in the States gave three hundred grains of iodide of potassium daily in bad cases. This was by no means the largest doses, for some gave two drachms of the salt five or six times in the twenty-four hours.

Dr. Rabaghate, of Bradford, said some cases of syphilis appeared to him to be quite incurable, and he mentioned a case which he had treated for a long time for ulceration of the feet, which would not be healed by blue pill, iodide of potassium, or any other remedy. He had not, it was true, tried Aix-la-Chapelle. Some syphilitic ulcers would heal up to a point and then suddenly break down. He sometimes thought there might be variations in the virulence of syphilis, as there was in the seeds of other diseases.

Dr. Rabaghate, of Bradford, made a criticism of the late work issued by the Royal College of Physicians of London, on the nomenclature of disease, which he considered was faulty in its classing such diseases as hydrophobia in a wrong group. That disease should be placed along with syphilis and the exanthems.

Dr. Payne defended the work. It had been issued in the same way as a dictionary, *i.e.*, to give an expression to the present use of medical language, not to make a new one.

Dr. Wilks also defended the work. It was, of course, absurd to place apoplexy in the class with diseases of the nerves, because it was a disease, not of the nerves, but the vessels; but still that was the usual way in which it was described, and the use of nomenclature was for describing the disease as known to the bulk of medical practitioners.

The Section then adjourned.

Quinine in Greece.—The Grecian Government has become alarmed at the increase in malarial fevers among the inhabitants of that country, which investigation has shown to be in a measure due to the poor quality and high price of quinine. It has therefore removed the duty from this drug, a measure which has already led to a reduction in its price, and has further determined to withdraw its sale from private hands and confine it entirely to government stores. It will buy only from the best and most reliable makers and sell at a very slight advance above the manufacturers' price, sufficient to defray the cost of transportation.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, June 5, 1885.

ALONZO B. BALL, M.D., PRESIDENT, IN THE CHAIR.

DR. BEVERLEY ROBINSON presented a patient, a woman, thirty-five years of age, married, who came under his observation at the out-door department of the New York Hospital, April 25th, when she said that for five or six months previously she had been scarcely able to breathe through her nose, she could scarcely sleep, and had apparently asthmatic trouble dependent upon the nasal affection. There was complete loss of smell, and the voice had nasal intonation. No air could be forced through the right nostril, and only a very small amount through the left. Dr. Robinson used Dr. Weir's gouge-forceps on the right side, and removed as much of the septum as he could tear off readily, and since the operation the patient had been considerably relieved. In these cases such an operation was not always necessary to obtain a cure, because there was considerable granulation tissue which could be removed by cauterization and other means milder than the use of the forceps. As occurs in all these cases after such an operation, there was a tendency on the part of the passages to close up somewhat, and the patient wore a rubber tube for four or five days. Dr. Robinson had also been obliged to cauterize the granulation tissue a few times, and also to apply monochloracetic acid.

The case was also interesting in the fact that the patient had not at any time suffered from impairment of hearing, although there had been nearly complete obstruction upon one side and complete upon the other. Again, she had not seemed to be very much annoyed with catarrhal trouble from the condition of the nasal mucous membrane, which, as a rule, was present under such circumstances. Furthermore, the asthmatic trouble had been very much improved. By means of cauterizations and the application of the acid, Dr. Robinson hoped that recovery might be completed without further use of the forceps.

The case was also interesting in the fact that while little or nothing was done in the left nostril, through which she could before scarcely breathe, at the present time she could breathe more freely through the left than through the right nostril, and the explanation which Dr. Robinson gave was that the tissues taken from the right side allowed the septum to fall toward the right, and in that way open up the left nasal passage.

The operation was performed under the local application of a ten per cent. solution of cocaine, which diminished the pain a good deal, although it did not remove it entirely. No perceptible effect was produced on the amount of the hemorrhage, and it was quite profuse.

DR. A. A. SMITH asked if there was any impairment of taste.

The *patient* responded that taste seemed to be impaired, as it seemed to her at times that she did not taste anything.

DR. ROBINSON further remarked that he did not regard the use of the burr and the dental engine as at all necessary in the treatment of such cases, and that the forceps were just as useful and much more easily obtained.

DR. A. A. SMITH directed attention to

THE SKIN ERUPTION AFTER THE USE OF ANTIPYRINE,

and asked if any of the members had observed cutaneous eruptions after the use of this drug.

THE PRESIDENT had seen very marked effects from it in one case, where the entire body was covered with a profuse, fine, papular rash, looking very much like the ordinary heat-rash. He thought it was by no means uncommon to see skin eruptions following the use of antipyrine.

DR. SMITH said that the eruption to which he referred consisted of large red welts, elevated above the surface, with perfectly white skin between them, resembling the urticaria which comes from taking quinine or eating shell-fish, and first appearing upon the extremities. In the first case in which he had noticed this form of eruption the patient had taken forty-five grains. In that instance the eruption was rather a purplish red, and looked not unlike that of measles, which began upon the upper extremities and extended over the entire body. At the same time, in the cases which he had noticed, perspiration was quite active.

DR. SAMUEL SEXTON then read a paper entitled

CATARRHAL INFLAMMATION OF THE HEAD, AND ITS EFFECT ON THE MIDDLE EAR.

The Society then went into executive session.

Correspondence.

OUR PARIS LETTER.

(From our Special Correspondent.)

DR. FERRÁN'S EXPERIMENTS—THE BLIND TO TAKE PART IN TELEGRAPHIC WORK—ESTABLISHMENT OF MORTUARIES—THE CRAZE FOR STATUES.

PARIS, July 24, 1885.

As must have been anticipated, the report of Dr. Brouardel's mission to Spain has led to much controversy, to which, however, I can do no more than refer here. The enthusiasm which attended Dr. Ferrán's anti-cholera inoculations at the commencement waned somewhat, but it has again revived, and no wonder, as the population, terror-stricken by the gradual but decided daily increase of the number of cases affected by the disease, and the great mortality therefrom, would resort to anything that would offer even the shadow of a chance of a remedy, whether preventive or curative, for such a dire disease. The consequence is that Dr. Ferrán and his coadjutors are as busy as they can be, for, from the reports which reach us, they inoculate from five hundred to six hundred daily.

The Spanish Government, after having interdicted Dr. Ferrán's inoculations, has again authorized him to continue them. Encouraged by this permission he has expressed his intention of coming to Paris, with the view of submitting his method to the Academy of Sciences, as he is a candidate for the Bréant prize, which is one hundred thousand francs, or twenty thousand dollars, and which was offered some twenty-five or thirty years ago for the best remedy against cholera.

At the meeting of the Academy of Sciences, on Monday last, M. Gosselin, reporter of the commission of the above prize, declared that before expressing any opinion on Dr. Ferrán's communication it will be necessary for the commission to be in possession of official and complete statistics relating to the inoculations already practised by him.

A great deal has been said about Dr. Ferrán's secret, but this physician himself declares that when a thing has been confided to another party it remains no longer a secret. Thus the Paris Academy of Sciences has been in possession of the secret for the last three months without being aware of it. In fact there is no secret at all, and if there is one it consists simply in the attenuation of the cholera virus, which is effected by the action of time, of air, or of heat. To another French mission, from Algiers, which is said to have been received by Dr. Ferrán with great courtesy, the doctor declared that the proper moment at which the cultures present the degree of attenuation necessary for inoculation is when the liquid contains granular corpuscles and commences to lose its alkalinity.

Whatever be the outcome of Dr. Ferrán's anti-cholera inoculations, there is one thing certain—the epidemic in Spain continues its course, and singles out its victims

with unrelenting rigor among the inoculated as well as the uninoculated. The reports that have reached Paris from reliable sources give as the total number of deaths from the disease for the whole peninsula, from the commencement of the epidemic to the 22d inst., twenty-two thousand!

The journal *L'Electricite* announces that apparatus are being prepared to enable the blind to take part in telegraphic work, which, it is remarked, will not be more difficult for them to manage than to play on a piano or an organ. It is also remarked that from the delicacy of their touch and their steady application to the occupation on which they are engaged, they would be quite competent to discharge such duties satisfactorily. It is strange that this idea has not been put in execution before now.

The Municipal Council of Paris has decided upon the establishment of mortuaries in different parts of the town for the use of persons dying in such conditions that it would not be convenient for their families to retain the corpse in their lodgings for the time required by law before interment. The aspect of the building, though simple, is to be elegant and in good taste. Each mortuary is to be composed of a rotunda, which will be freely ventilated by a central chimney. In one portion of the building there will be arranged ten double cells. In each pair one cell is destined for the corpse, while the other is intended for the friends, who will be separated from the former by a glass wall, through which it can be seen. Each double cell is separated from the others.

There seems to be a rage for statues and busts just now in this country. I do not mean to say that the men whom they are intended to represent are not deserving of the honor, but there have been so many erected lately that it can be no longer considered a mark of distinction. In one week alone during the present month there have been unveiled three statues in Paris—one for Voltaire, the great satirical writer and philosopher; another for Béranger, the greatest lyric poet that France has produced; and the third for Pinel, the eminent French physician, who particularly distinguished himself for the important improvements in the treatment of lunatics.

THE "COUNTRY DOCTOR" AND THE INTERNATIONAL MEDICAL CONGRESS.

To the Editor of The Medical Record.

Sir: There is a class of men in these United States known as "country doctors," who have a great interest in the International Medical Congress. They have watched the organization and the re-organization, read the various journal and other comments, but have kept silence. I hope, in speaking as one of them and for them, that I correctly represent them.

Thoreau says of the Concord farmers: "They are greater men than Homer, or Chaucer, or Shakespeare, only they never got time to say so; they never took to the way of writing." This may not be strictly true when applied to city *vs.* country doctors; nevertheless, on account of numbers and talent, they deserve to be heard on this question of organization of the "Congress."

The doctors of the towns, villages, and country places of this land outnumber those of the cities; they are, perhaps, not so scholarly and scientific, they don't have time to write books and journal articles, and do many other legitimate and illegitimate, honorable and dishonorable, things by which to gain notoriety, as do their city friends; but they do as much hard work, more actual study of cases, and in their treatment display as much common sense, and attain as great success in practice. Nor do they concern themselves much about codes of ethics. They have learned that when men are not ethical, codes cannot make them so; and when they are, codes are unnecessary.

This class of men (country doctors) has been missed entirely by both committees. Not even so *small* a compliment has been paid them as a membership of a council. But no complaint has been heard. They are content, and preferably so, to see their friends shine.

In 1884 the American Medical Association selected a committee of talented, wise, honorable, well-known, and competent men. It knew and trusted them, hence gave them unlimited power. They acted. Their report (which can no doubt be somewhat improved) was a most excellent one. We joyfully accepted it and anticipated a grand international meeting. We were glad to see no code, or sectional or other embittering elements introduced to disturb peace and harmony.

Some *city* men, not glad to be unnoticed, as were their country compeers, and having no better right to representation, have disturbed this peace and harmony by getting the American Medical Ass. (a very appropriate name), to set aside its work of 1884; to insult the committee, by not receiving its report; and to insult the members of the Association of 1884, by condemning their action in thus giving so much power to the committee.

This undoing may be legally correct, as Mr. Randall says, but it is not honorable, nor even *ethical*, if we examine the code carefully.

The code has been made to bear the responsibility of this trouble, which is a cowardly ruse. The poor thing never did any harm or any good; it is imbecile, and why abuse it?

I think I state the truth when I say that the "country doctors" of the United States oppose the introduction of the code question *at all* in the "make up" of the congress. What virtue has the code when its adherents conduct themselves so disgracefully as they did last winter in the New York Academy of Medicine? True, the code exists as a printed form, but not as a working fact. It ought to be buried with the transactions and deceased members of the Association.

The country doctors want the congress. They desire to see and hear the men whose works they study. They wish the membership to be on a broad basis, so that they can all attend. They want no code or other embittering thing to be mentioned. They want to be represented by the few who lead the profession and are "known and read of all men," not by the mediocrity (unknown) who are no better than themselves. They therefore ask the return to the original committee and its arrangements; or, that the profession of the United States (not the American Medical Ass.), in whose name the congress was invited, have a meeting, appoint a new committee, and organize the entire programme anew. If neither of these can be accomplished, let the congress be held in another land than ours.

Spencer M. Free, A.M., M.D.

Dagus Mines, Pa., August 24, 1885.

HYPODERMIC INJECTIONS OF QUININE IN MALARIAL FEVERS.

To The Editor of The Medical Record.

Sir: The article in The Medical Record of July 25th, entitled "The Success of Hypodermic Injections of Quinine in Malarial Fevers," has led me to send you a brief account of my experience in the treatment of malarial fevers by this method. About a year after my arrival in India I was placed in charge of a general hospital and dispensary situated about seventy miles from Madras, in a town which, with its suburbs, contained a population of over thirty thousand inhabitants. In the year 1876 I was induced, by several articles published in the British and Indian medical journals, to try extensively the treatment of intermittent and remittent fevers by the hypodermic injection of sulphate of quinine. As over nine thousand patients were annually treated in this hospital and dispensary, I was enabled to try this treatment on a large scale.

At first I employed a solution made with ordinary sulphate of quinine and dilute hydrochloric acid, and I was astonished at the wonderful effect produced by these hypodermic injections. Cases that had been taking twenty and thirty grains per diem by the mouth without any apparent effect were cured at once by the injection of from eight to twelve grains. In the first 100 cases subjected to this treatment I had 5 cases of abscess following the injections. Not being satisfied with this result, I determined to try a solution of the quiniæ sulph. solubil. (an English preparation very similar to our bisulphate), prepared with a little tartaric acid. I found this a great success, I might almost say a perfect success. I have used this injection in over two thousand cases without any bad effects, with the exception of one case of small abscess. Even in this case I am inclined to think there would have been no abscess if the patient's arm had been firmly held, and if the operator had not been interrupted by the violent movements of the chill.

During the last three years of my residence in India I was settled on the Neilgherry Hills, where I had a good opportunity of carrying on this mode of treatment by hypodermic injection, and of ascertaining that it was as efficacious with Englishmen as it had proved to be with the natives. Near the tops of these Neilgherry Hills, at an elevation of about six thousand and seven thousand feet above the level of the sea, are situated the two large sanitaria of South India, with an English population of from five thousand to ten thousand, according to the season of the year. The climate on these hills at this elevation being cool and healthy, Europeans are able to live there in comfort and bring up their families. A great number of English gentlemen are residents upon these hills, being engaged in the cultivation of coffee, tea, cinchona, or "planting," as it is termed. To work their large and valuable estates great numbers of native laborers are employed. These plantations are situated on the slopes of the hills, at an average elevation of three thousand five hundred feet, and are therefore below what is called "fever range;" that is, the hilly or mountain tracts of South India are generally infested with malaria until you reach an elevation of over five thousand feet. At certain times of the year it is unsafe to sleep even for a single night on these estates. The native laborers are obliged, however, to live down there, and are therefore constantly prostrated with fever. I have frequently been called to visit one of these estates, and in a single morning would often have to administer hypodermic injections of quinine to over fifty of these native laborers. In addition to constantly and regularly employing hypodermic injections of quinine in the treatment of malarial fevers, I administered quinine in this way quite frequently in puerperal septicæmia, where I found it had a very beneficial effect.

A considerable number of cases of puerperal septicæmia occurred in the lying-in ward of the General Hospital and Dispensary already alluded to. The native doctors and midwives have no real knowledge of anatomy and physiology, and they often employ most violent means to hasten difficult labors. It is therefore not at all surprising that many cases of septicæmia and peritonitis result.

I have already mentioned that the solution generally used was composed of quiniæ sulph. solubil., tartaric acid, and distilled water, the strength of the solution varying from fourteen per cent. to twenty per cent. With adults I usually injected two syringefuls (that is, from five to eight decigrammes) into the upper and outer part of the arm, or on the back of the shoulder, pushing the needle well down into the subcutaneous tissues and even into the muscle. The pain produced was always trifling and of short duration. Sometimes a little redness and very slight swelling occurred, but soon disappeared. I once administered to an English army officer, taken suddenly with a congestive chill, eight syringefuls of a sixteen per cent. solution in twelve hours, with the very best of results, except that he was somewhat deaf for a day or two. Of course, I do not mean to assert that this treatment by hypodermic injection always drove the malarial poison entirely out of the system or effected a permanent cure; but one or two injections nearly always broke up the fever and effected a cure at the time so that a patient would have no return of the fever, unless he exposed himself anew by visiting a locality where malarial fever was rife or allowed his general health to run down. I had two patients—wealthy English gentlemen—who were accustomed to come every few months and get me to give them a hypodermic injection of quinine as a prophylactic measure when they were about to visit a notoriously feverish locality. During the eighteen months that I have been practising here in Chicago, I have made use of hypodermic injections of quinine several times with perfect success. In conclusion, to show what perfect confidence I have in this mode of treatment, I have only to mention that I have had quinine injected into my own arm on two occasions.

206 Twenty-eighth Street, Chicago, Ill.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 22, 1885, to August 29, 1885.

Cronkhite, H. M., Captain and Assistant Surgeons Relieved from duty at Fort Reno, Indian Ter., and assigned to duty as Post Surgeon, Fort Hays, Kan. S. O. 129, Department of the Missouri, August 26, 1885.

Powell, J. L., Captain and Assistant Surgeon. Relieved from temporary duty at Fort Leavenworth, Kan., and assigned to duty as Post Surgeon at Fort Lyon, Col. S. O. 128, Department of the Missouri, August 25, 1885.

Kane, John J., Captain and Assistant Surgeon. Granted leave of absence for one month, to take effect when his services can be spared. S. O. 195, A. G. O., August 26, 1885.

Ebert, R. G., Captain and Assistant Surgeon. Assigned to temporary duty with U. S. Troops at Riverside Park, N. Y. S. O. 179, Department of the East, August 24, 1885.

Stephenson, William, First Lieutenant and Assistant Surgeon. Granted leave of absence for one month, to take effect September 1, 1885. (Fort Niobrara, Neb.) S. O. 79, Department of the Platte, August 20, 1885.

McCaw, W. D., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at the camp of the troops near Kiowa, Kan. S. O. 128, Department of the Missouri, August 25, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending August 29, 1885.

Jones, William H., Surgeon. Detached from the Wachusett, and waiting orders.

Precocious Menstruation.—Dr. Denver reports in the *Gazeta Medica di Bahia* the case of an infant who began to menstruate at the age of two months. The menses appeared regularly every four weeks, and continued for four or five days. On one occasion they ceased for a period of three months, and the child became ill, but recovered her usual good health upon their restoration. She was examined when two and a half years old. She weighed forty pounds, and her face was that of a girl ten or twelve years old. The breasts were the size of small apples, the mons veneris was covered with hair, and the labia minora and majora were well developed.

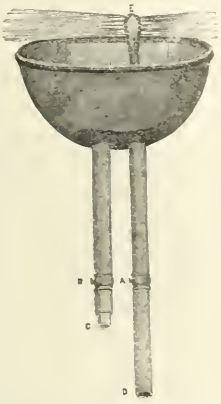
New Instruments.

AN INTRA-VAGINAL CUP SYRINGE.

By E. P. FRASER, M.D.,

PROFESSOR OF GYNECOLOGY, MEDICAL DEPARTMENT, WILLAMETTE UNIVERSITY, PORTLAND, ORE.

THE proper administration of therapeutic vaginal injections, in the dorsal recumbent position with hips elevated, is almost impossible, owing to the discomfort and annoyance attending the use of the various contrivances for receiving the injection fluid as it leaves the vagina. These are entirely overcome by the simple instrument shown in the accompanying woodcut.



The instrument consists of a soft rubber cup, through the bottom of which pass the afferent tube (D), with hard rubber nozzle, and the efferent tube (C), to which is attached a waste pipe two and one-half feet long for conveying the fluid into a receptacle under the bed or table. These tubes are supplied with simple stopcocks (A and B). The nozzle (E) may be removed from the cup when desired.

The cup is readily introduced into the vagina, and when there it exerts pressure on the vaginal walls sufficient to prevent the escape of the fluid except through the efferent tube. The nozzle of any style of syringe may be inserted into the afferent tube, and any quantity of water may be injected with perfect comfort to the patient.

The patient lying on the back, with hips slightly elevated, the fluid will dilate the upper portion of the vagina, and come in contact with the entire surface, while the more sensitive parts of the vagina, vulva, and perineum are completely protected in case very hot water is used.

When it is desired to make an application of glycerine or other fluid substance to the cervix, the nozzle (E) must be removed, and then, the efferent tube being closed, the fluid is introduced through the afferent tube and allowed to remain as long as required. If preferred, the instrument may be allowed to remain *in situ* after the application has been made, thus serving as a temporary support to the uterus in the place of cotton or oakum tampons.

I have derived much satisfaction from the use of this instrument, and gladly give it to the profession, believing that it needs only to be tried to be appreciated.

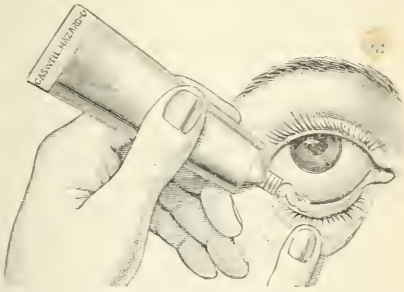
These instruments are manufactured by Geo. Tiemann & Co., New York City.

COMPRESSIBLE TUBES FOR APPLYING OINTMENTS TO THE CONJUNCTIVA.

By JOSEPH A. ANDREWS, M.D.,

NEW YORK.

PATIENTS to whom is intrusted the application of an ointment to the eye are not usually careful to cover the vessel containing the former; consequently, in a few days the ointment contains dust or other foreign material, which it is objectionable to apply to the conjunctiva. Also the brush with which the ointment is applied, is rarely kept clean. By means of the simple contrivance pictured above, these objections are quite overcome. These tubes are similar to those in which artists' pigments are put up, and they really are a great convenience; for the tube being made of a thin compressible metal, the ointment is readily squeezed out upon the conjunctiva, and the application becomes as simple as dropping a fluid into the eye; and when the little cap is



screwed on over the mouth of the tube, the latter is secure against the entrance of any foreign material, and may be carried in the pocket. The most convenient size is that which holds about two drachms of ointment. The application is made by directing the patient to look upward, and while you draw down the lower lid with the index finger, the ointment is squeezed out upon the lid. They are manufactured by Mr. Ford, of Messrs. Caswell, Hazard & Co., New York.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending August 29, 1885:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.								
Aug. 29, 1885.....	0	37	14	4	5	23	0	0
Deaths.								
Aug. 29, 1885.....	1	8	4	2	6	14	0	0

TREATMENT OF BOILS.—Halle recommends the following application in furuncle. Tannic acid. 1 part: powdered gum acacia, 1 part; tincture of arnica flowers, 2 parts. This is to be painted over the boil and for a little distance around it, several coats being applied until it forms a thick and firm covering. Halle states that this mode of treatment quickly relieves the pain and diminishes the swelling. When taken in time, the boil disappears without the formation of pus; and when this has already occurred, the application causes the extrusion of the core and prompt healing of the furuncle.

REMARKABLE FECUNDITY.—A correspondent of the *Deutsche Medicinal Zeitung* reports the case of a peasant woman, married, at the age of eighteen years, in February, 1873, who has since that time given birth to ten living children, besides having had two miscarriages. At the time of writing, July of the present year, she was in the sixth month of her thirteenth pregnancy.

A FACE WASH.—M. Vigier proposes a lotion of one part boracic acid to one hundred of rose-water, perfumed as desired, as suitable in the treatment or prevention of pimples, acne, or roughness of the skin. It is harmless and can be used for an indefinite period. The face is to be moistened with it morning and night.

The Disinfection of Sleeping Apartments.—Professor König, of Göttingen, in an article on this subject in the *Centralblatt für Chirurgie*, says that at one time, while he was practising medicine in Hanau, he suddenly discovered that his bed-room was thickly inhabited by bugs. A friend assured him that he could speedily rid him of the pests, and proceeded to fumigate the apartment with corrosive sublimate. The success of this measure was most gratifying, and when the room was opened the dead bodies of various kinds of insects were seen strewn about the floor. This incident led the writer to hope that the same means would be effectual in destroying the infectious elements of contagious diseases, and a trial in private houses after scarlet fever or measles, and in hospitals after erysipelas or pyæmia, gave most satisfactory results. Since adopting this method, he has never seen a second case of a contagious disease which could be attributed to infection remaining in the room in which the patient had been confined. The mode of procedure is very simple From one and one-half to two ounces of corrosive sublimate are put on a plate over a chafing-dish, and then the windows and doors of the room are closed. At the expiration of three or four hours the windows are opened, and the apartment is thoroughly aired. The person entering the room should take the precaution to hold a sponge or a cloth over the mouth and nose in order not to inhale the vapor. The following day the windows are again closed and some sulphur is burned in order to neutralize any of the mercurial fumes which may still linger about the furniture and other articles. The room is to be again aired and cleaned, and will then be ready for occupancy.

Suicides in Lyons.—There were 99 cases of suicide in Lyons during the year 1883, of which 72 were men, and 27 women. The means employed were, in the order of their frequency: strangulation, 35; drowning, 26; poisoning, 13; fire-arms, 13; asphyxia from charcoal fumes, 6; jumping from a height, 5; cutting implements, 2.

The Treatment of Lupus in Prague.—Dr. Charles C. Ransom, of Richfield Springs, N. Y., writes from Prague, giving an account of the treatment of lupus as practised by Professor Pick of that city. This method is founded upon the theory that lupus is an infectious disease, due to the presence of a bacillus, probably the tubercle bacillus, which finds lodgement in the corium. The absolute proof of this theory is wanting, since, as yet, experiment has failed to show that lupus can be produced by inoculation of the tubercle bacillus in the skin. But the weight of evidence from clinical observation and histological investigation is so strong as to leave little doubt but that lupus is a form of tuberculosis. The indication for treatment, based upon this theory of the etiology, is plainly to destroy the bacillus. Since no agent has yet been discovered which will directly kill the parasite without at the same time producing the death of the tissue in which it resides, it is necessary to work for this end indirectly by the production of cicatricial tissue at the seat of disease, and thus cutting off the blood-supply upon which the bacillus depends for its existence and development. But it is desirable, while occluding the capillaries, to avoid disfigurement in those cases in which the face is the seat of the disease. Professor Pick has found, after a long series of experiments with different chemical caustics, that potassa is the best, as the resulting scar is less richly supplied with blood-vessels than that following the employment of other caustics, such as arsenious acid, corrosive sublimate, nitrate of silver, and the like. This is accordingly used by him in parts where the deformity is not a matter of importance. In lupus of the face, however, in cases in which the disease itself has not already produced irremediable disfigurement, he employs the method of scarification, with the three- or four-bladed lupotome of Veiel, in combination with the galvano-cautery. The patient is subjected to the scarification every other day, a new part being selected at each sitting until that first operated upon is healed. The incisions are carried just through the diseased part into the firm healthy tissue beneath. The amount of surface operated upon each time depends much upon the endurance of the patient. When the part first scarified is healed, the operation is repeated, the cuts being made so as to cross the first ones. The wounds made by the lupotome are dressed with an antiseptic solution. The first part of the treatment is continued until the entire surface involved in the morbid process is converted into cicatricial tissue. In this will now be noticed numerous little lupus nodules, the size of a mustard-seed, which are destroyed with the galvano-cautery needle. But little use is made of anæsthetics as they have been found impracticable; cocaine was extensively tried last winter, but gave little or no satisfaction. Dr. Ransom reports a number of cases in which he was able to verify the favorable results claimed for this mode of treatment. They were some of the more severe cases which he saw at Professor Pick's clinic, and in every one the result was most satisfactory. The ulcerations, when they existed, were healed, and the nodules and points of infiltration were completely eradicated. The resulting cicatrix was smooth and flexible, of a lightish color, and in no way deforming, except, of course, in those cases in which there had been loss of tissue prior to the commencement of treatment. The permanence of the cure is shown by numerous patients, who report from time to time, upon whom the scarifications were practised ten or even fifteen years ago.

The Way to Prepare Surgical Sponges.—The following is Mr. Lawson Tait's method of preparing the sponges, and but one person is trusted to do this: New sponges are first put into a large quantity of water with sufficient muriatic acid to make the water taste disagreeably acid. They remain in this mixture until all effervescence has ceased and all the chalk is removed. For this purpose it may be necessary to renew the acid several times. The sponges are afterward carefully and thoroughly washed, to make them as clean as possible and free from every rough particle. After being used at an operation, they are first washed free from blood, and then put in a deep jar and covered with soda and water (one pound of soda to twelve sponges). They are left in this about twenty-four hours (or longer if the sponges are very dirty), and then they are washed perfectly free from every trace of soda. This takes several hours' hard work, using hot water, squeezing the sponges in and out of the water and changing the water constantly. Leaving them to soak for a few hours in very hot water greatly assists in the cleansing. When quite clean, they are put in a jar of fresh water containing about one per cent. of carbolic acid, and after being in this for twenty-four hours they are squeezed dry and tied up in a white cotton bag, in which they are left hanging from the kitchen ceiling (being the driest place in the house) till they are wanted. —*American Journal of Obstetrics.*

How to Abort Typhoid Fever.—Dr. Jacob S. Horner, of Lanesville, Ind., sends his testimony to the value of the abortive treatment of typhoid fever, as sketched in The Medical Record of August 4, 1883, by Dr. J. O. Davy, of Springfield, Ohio. He writes that, at the time the article appeared, he had under his care a personal friend suffering from a very grave attack of typhoid fever. The disease was threatening to terminate fatally, despite the doctor's care and skill, but immediately upon beginning with Dr. Davy's remedies an improvement was noticed, and the patient eventually recovered. Dr. Horner adds: "I have used cohothedra compound in my practice since the latter part of August, 1883, and it has in my hands proved itself almost, if not actually, a specific in the treatment of enteric or typhoid fever. It gives speedy relief to all the distressing symptoms, such as high temperature, foul and dry tongue and mouth, delirium, etc. If the treatment is commenced

before the bowels are distended with gas, there will be no tympanites, and but slight tenderness and gurgling in the iliac fossa. Indeed, I can say I have had no case in which my patients were not quite or comparatively comfortable within twenty-four hours. All the febrile symptoms subside and convalescence is fully established in from five to eight days if the plan of treatment, as given in Dr. Davy's letter, is faithfully carried out. I should now feel that I was guilty of criminal neglect to my patients were I to attempt to treat a case of typhoid fever without this new American antipyretic, cohothedra compound." Dr. Horner adds that he has not hitherto kept records of his cases, but intends henceforth to do so, in order to demonstrate in a convincing manner the value of this remedy in typhoid and typho-malarial fevers.

Short Notes of Wounds of the Heart with Survival for an Appreciable Time.—Dr. E. Stirling, of Cleveland, O., sends us the following: "I made a post mortem before Coroner Young, in the case of a man killed by a stab in the heart. After receiving the blow he ran out by the open door on to the street, forty-one feet, before falling dead. The cut was into the left ventricle, of size sufficient to admit the forefinger. In 1856, while in San Francisco, I saw a man who after receiving a pistol-ball through the heart ran seventy-five feet before falling. I visited the spot a few minutes after the occurrence but did not witness the examination. One of the doctors present informed me that the ball passed through the upper and outer portions of the left auricle. All are conversant with the case of Jim Pool, the pugilist, who carried a pistol-ball in his heart for many days. The heart of a deer was shown me, by a doctor in Michigan, that contained well imbedded in the ventricle a rifle-ball, of forty to the pound size. It was positively known that the deer received the wound two years before, and had carried the ball this length of time."

How can we Raise the Standard of Medical Education?—Under this caption a correspondent sends to The Record his views of what is necessary to elevate the average of medical attainments. He writes that he was present at the last meeting of the State Society, when the bill "to regulate the licensing of practitioners of medicine or surgery and to further regulate the practice of medicine or surgery," came up for discussion. And he "listened with feelings of painful regret," because he was "forced to recognize as distressingly prominent in the remarks of some speakers a selfish jealousy amounting to a mere trade instinct." He thinks that it is proper to ask the State to protect the feeble against the ignorant greed of charlatans, but that it is ignoble to beg protection for the profession itself. The solution of the problem is in our own hands, and it is evidently by us alone that the standard can be raised. We should see to it that those are not admitted who embrace the profession of medicine from base motives, just as men of a similar kind are excluded from the ranks of the ministry. "The lack of moral force and intellectual character, which is sometimes complained of in our profession, is the result of our own sins. We at least ought to know the requirements for our profession; other qualities than erudition are necessary to make a physician. The very age at which a young man is supposed to enter a physician's office to read medicine for three years, as is the custom, is the one in which the habits are formed or forming. A little care and observation on the part of the preceptor at this time will enable him to perceive pretty accurately whether the candidate is possessed of all the qualities necessary to make the true physician. If we send to the colleges only gentlemen, in every sense of the word fitted to become physicians, our colleges will necessarily be raised to a much higher standard without seeking State aid. On the other hand, if the proposed law were enacted, the feeling of individual responsibility, which is our only safeguard, would be removed; and we should delegate the keeping of our conscience to the State Board of Examiners, who, from the very nature of their functions, would exclude all considerations of the moral fitness of the applicants." At the same time our correspondent deprecates any steps which would tend to diminish the value of competitive examinations. "Ours is a profession calling into action all the acute perceptions of the human intellect; but not one whit less than learning and science does it require an innate common sense."

A Dutch Account of Hottentot Pathology.—A Dutch practitioner who has lived for twenty years in South Africa sends to an Amsterdam medical journal some particulars of native customs and beliefs. The uterus is supposed to have a great tendency after parturition to fly upward, and consequently after the second stage of labor the funis is carefully tied to one of the woman's great toes, so as to prevent the placenta from slipping away, and as soon as the third stage is completed she is tightly bound with a cloth or a cord at the level of the umbilicus, for if not the restless uterus would ascend into the breast. After the birth of a still-born child nothing can prevent the womb from betaking itself into different regions, and then performing unpleasant and painful gyrations. The writer mentions an old native woman who came to him with a scirrhus of the mamma. She complained of occasional pain in the abdomen, but was not seriously concerned about it, for said she: "I know what that is; it is the womb going round; have I not had a still-born child? From that time there can be no rest for the womb; he (the womb) keeps springing round and round, not always, but at times, perhaps for three months, and then for a fortnight he is still. Sometimes he sits here (indicating the spleen); sometimes here (touching the right breast); sometimes he sits behind my shoulder-bone, and then he burns like a coal of fire." The uterus has to answer in the native mind for most of the ills to which female flesh is heir; has she a colic, sickness, or any abdominal trouble, it is always the old story—"the womb is going round." When listening to a gesticulating patient describing her malady and enunciating her diagnosis of the cause, it is frequently somewhat difficult for a medical man to keep his countenance. It is utterly useless for him to attempt to reason with the woman or explain to her the absurdity of the position she has taken up. She will only doubt his skill, and scornfully reply: "Doctor must not say it is not so, for I know that it is." Among the natives the new-born babe is treated to a purifying draught of the father's freshly-passed urine. The whites, some of whom are nearly as ignorant and superstitious as the natives, employ a quack "wonder-essence" as a substitute.—*London Lancet.*

Fatal Paraplegia Due to Sarcoma of Vertebræ.—Dr. G. W. H. Kemper, of Muncie, Ind., reports the following interesting and rather unique case: Mrs. B——, aged forty-four, married, with three children, came under his observation in August, 1884. Six years previously a carcinoma had been removed from the left mamma, leaving half the gland. About five years later (May, 1883) this remnant had become painful and indurated and was also removed. Soon after a third tumor appeared in the cicatrix, followed by enlargement of axillary glands. A perceptible prominence was observable over the eighth and ninth dorsal vertebræ. At this time she came under Dr. K——'s observation. She had a very slight temperature; pulse, 85. Functions of bladder, rectum, and uterus normal, with occasional pains in extremities. She was lying upon her back with her lower extremities extended. She had the power, rather feebly, however, to flex and extend the lower extremities, and could very well control the movements of the upper extremities. She already had lain in this position for six weeks when we saw her, and had been treated by a homœopathic physician for rheumatism. She was utterly unable to raise her head or turn in bed; in fact, it was at the cost of very great pain that she

could be even carefully turned or lifted temporarily from her supine position. The spine showed upon pressure considerable tenderness over the greater portion of its extent, and was so inflexible that the least curving in any direction gave rise to distressing pains, especially cervico-brachial. A peculiar symptom that she dwelt upon at this and other times in the course of the disease, was "a feeling as if the contents of the abdomen would fall out through the abdominal walls." This sensation was disagreeable rather than painful, and had annoyed her for some weeks. The history of the case, together with the result of examination, suggested a diagnosis of spinal irritation, complicated possibly with congestion and due to malarial origin, as she gave a malarial history. A general tonic course with quinine for the malaria benefited her but little. The spinal symptoms gradually became more pronounced, and finally paraplegia, accompanied by neuralgic pains, invaded successively the right arm, hip, thigh, and leg. Increasing numbness, especially in the lower extremities, led to the conclusion that the previous diagnosis was incorrect and that the trouble was really due to spinal compression, resulting from a malignant vertebral growth, secondary to the previous mammary neoplasms. In December the patient died, having suffered for some weeks previously from dyspnœa, loss of normal action of rectum and bladder, "girdle" pains and various abnormal sensations. One small bed-sore formed. Toward the end the pulse grew more rapid and intermitted occasionally. An examination of the vertebræ above mentioned revealed a neoplasm consisting of round and spindle cells of a typhoid type, so arranged that the spindle cells were so placed as to form trabeculæ with intervening alveolar spaces. Within the latter were the round cells. In other words, the growth was an *alveolar sarcoma*.

Useful Agents in the Treatment of Scarlet Fever.—When lecturing upon scarlet fever Professor Da Costa mentioned the following agents as being of use: 1. Carbolic acid, gtt. ½, a dose for child two years of age; give in mint water. 2. Ammonium carbonate, gr. ij., every two hours, to child ten years of age. 3. Potassium chlorate, ʒ j., in water, ♁ j.; patient to drink this in twenty-four hours. 4. Salicylic acid when high temperature is present. 5. Small doses of chloral. Always keep skin active, and if heart be weak, give digitalis—if arterial tension be high, give aconite. When much exudation has occurred, he prescribed, for its solvent action: ℞. Ammonii carb., gr. x.; Liquor. ammon. acetat., f ʒ ss. M. Sig. Every four hours. If there is much depression, prescribe also quinia and digitalis in combination.—*Col. and Clin. Record.*

Buckwheat Flour in the Treatment of Diabetes.—Dr. Y. H. Bond, of St. Louis, Mo., writes: "Some time since I read an article in your journal upon the subject of 'Diabetes Mellitus,' in which buckwheat flour was said to have been used, as the exclusive bread diet, with the result of a disappearance of the sugar from the urine. In support of that observation, I herewith report my experience in the trial of the same agent on the only patient that I have treated for that trouble since reading the article referred to. On May 11, 1885, I was consulted by Mr. W——, aged sixty-three, of Scotch descent, possessed of fine physical development and a stable nervous system, resident of the State of Vermont. His only ailment consisted in the passage of an excessive amount of water, which he stated had troubled him for more than a year past, and that the amount of water passed was about the same every day. He passed from 9 P.M., May 13th, to 9 P.M., May 14th (twenty-four hours), three quarts of water. On examination sugar was found in abundance. I continued to examine his urine at varying intervals up to June 15th, discovering little or no variation in its quantity or character up to that time, pursuing this course with the view of determining the constancy of the sugar, amount, etc., uninfluenced by treatment, in order that I might know what, if any, effect was produced by my management of his case. On June 15th I instructed him to discontinue the use of Irish potatoes; and, in place of bread made from wheat flour, or corn meal, to use buckwheat flour, prepared as his taste might prompt. I am satisfied that my instructions have been faithfully complied with. The quantity of urine passed grew less in a very short time, the amount passed from 5 P.M., July 7th, to 8 A.M., July 8th, being one pint only—and on examination was found to contain no sugar. I examined his urine again on the 11th ultimo, with the same result—no sugar and the same reduced quantity."

A Substitute for Carbolic Acid.—The extraordinary power of naphthol as an antiseptic and disinfectant has been known for a long time, but its disagreeable smell, and the difficulty of preparing it in a pure state, with the occasional toxic action of the crude naphthol, have hitherto prevented its general adoption as a remedial and antiseptic agent. Justus Wolff, a chemist interested in coal-tar products, has recently succeeded in producing it in a pure and odorless state in well-defined crystals, and he claims its antiseptic action is much greater than that of carbolic acid. Recent research has demonstrated that the toxic effects of crude naphthol were due to the impurities it contained. Dr. Shoemaker, of Philadelphia, in a paper read before the Philadelphia County Medical Society, on the "Medical Use and Value of Naphthol," conclusively proved the non-poisonous character of the purified or odorless naphthol by taking large doses internally. It has no corrosive action on the skin, and will not injure textile fabrics. As a remedial agent it is said to act with greater efficiency than carbolic acid, and if so, the fact of its being absolutely odorless will make it a desirable substitute for the latter. It is expected that it will shortly be manufactured in large quantities and introduced as a substitute for carbolic acid.

More about the International Congress.—"It [the new committee] has, however, performed, in our judgment, the most stupendous work of supererogation ever exacted from a body of intelligent men. We are totally unable to see how the fortunes of the Congress have been a tithe benefited by the changes made. On the contrary, it has suffered immensely in the eyes of all unbiassed thinkers by this unnecessary controversy about representation on Sections and 'New Code' principles. As the Congress now stands organized, we much doubt its ability to attract that attention as a scientific body it was entitled to. How can those men interested in pure science feel that same interest in the fortunes of an organization handicapped with contentions for offices and ethics, and weighed down with that ponderous body, the American Medical Association?"—*Maryland Medical Journal.*

"The committee did the work expected of it, and with less malice than would have seemed possible, but with sufficient thoroughness, we fear, to put an end to the prospects of a successful and creditable *international* congress, and adjourned to meet in St. Louis on the first Monday in May, 1886. . . . These gentlemen proposed to aid and participate in the discussion of questions of medical science, not of medical ethics, medical politics, or of square miles of territory. There will, however, be more offices, although less congress, for those who prefer such discussions and such distinctions to a harmonious gathering of scientific men searching for truth; and we hope somebody may be happy, if it be only for a short time.—*Boston Medical and Surgical Journal.*

Trichloracetic Acid.—This substance is said to be an excellent antiseptic agent. Dr. Filipovich has employed it with success, in an aqueous solution of the strength of 2½ to 5 per cent. in the treatment of wounds, erysipelas, soft chancre, etc. He has also given it internally in gastric catarrh and cancer, in doses of 2 to 4½ grains (0.12 to 0.30 gramme) for adults.

THE MODERN METHODS OF TREATMENT OF GUNSHOT WOUNDS.

A CONSIDERATION OF THE PRINCIPLES OF NON-ANTISEPTIC OCCLUSION; PRIMARY ANTISEPTIC OCCLUSION; PRIMARY, INTERMEDIARY, AND SECONDARY DRAINAGE; RESECTIONS, ETC.; EARLY VERSUS LATE ANTISEPSIS IN MILITARY SURGERY, AND THE PRACTICABILITY OF ANTISEPTIC METHODS IN WAR SURGICAL PRACTICE.

BY HENRY I. RAYMOND, A.M., M.D.,

ASSISTANT SURGEON, U.S.A.

THERE seems to be an impression almost universally prevalent among the laity, and widely so among the medical profession, that a gunshot wound calls loudly for some one or all to do something.

To combat this indiscriminate tendency on the part of surgeons to be "overmeasurely busy" (übermässig geschäftig) in the treatment of gunshot wounds, is in some measure the purpose of this article. To this end it is desired to set forth the claims of the several methods of treatment; to endeavor to assign to each its relative precedence; to compare the relative value of early and late antisepsis, inquiring as to whether the application of the former is optional or obligatory for securing the further favorable course of the reparative wound processes; to consider the practicability of the antiseptic methods in war surgical practice where the surgeon has to deal with a multiplicity of wounded under the conditions of bad hygiene and haste, incident to the exigencies of field service; and finally, to consider the claims of the several primary methods of treatment as adapted to injuries of different parts and regions of the body, and the wide range of applicability of the method by primary antiseptic occlusion. The recent marked advancement in this branch of surgery is largely owing to the lessons drawn from the practical experiences of military surgeons in our late wars and campaigns.

Scarcely till the time of the Franco German war had it begun to be recognized as an established principle of practice that a gunshot wound might heal without drainage and without apprehension of pus secretion. In the riots that occurred in the streets of the French metropolis subsequent to the war of 1870–71, a number of cases was observed by surgeons, after healing was complete, in which the repair of the wound-track had taken place under a blood-scab or crust, by the *laisser faire* treatment which befell them, owing to the guilty fears of the wounded rioters to present themselves before the Parisian surgeons.

In the War of the Rebellion, but two decades gone by, antiseptic occlusion was not practised at all, and primary occlusion without antiseptic precautions, when practised, was not, in the main, founded on well-understood or determined principles of war surgical practice as later developed in the comparatively recent European wars.

Before going on, it behooves us to start out with technical phrases clearly defined, and methods of treatment simply classified, so as to avoid all ambiguity of words or meaning.

These methods may be severally classified and defined as follows:

1. *Non-antiseptic occlusion*—*i.e.*, the healing of a wound under the simple blood-clot, scab, or crust, without the intervention of surgical aid or appliances—hence, without instrumentation and without antisepsis or drainage. It is Nature's best effort, unaided. It is a better effort in many cases than a misguided surgical interference.

2. *Primary antiseptic occlusion*, or the immediate application of an occlusive covering to the wound on antiseptic principles. The *immediate* application implies at the earliest possible moment after the injury, for although several hours, or even a day or two might intervene without injury between the time of reception of the wound and its occlusion, yet inasmuch as this time or interval is only a relative one and cannot be determined *a priori* in any given case, the occlusion should take place at once, to preclude the possibility of infection from without.

In testing the merits of antiseptic occlusion, it seems not to be enough to declare that wounds were closed on the same day or the next day at farthest, for some wounds become unsuitable for occlusion even a few hours after their infliction; hence in so far do reports of unsuccessful cases lose assurance where an interval of time is permitted to elapse before occlusion is practised. This is not denying that a wound may heal by occlusion, even if the dressing is applied for the first time hours or days after the injury, but such cases present no tokens by which they may be recognized *a priori* by the surgeon; hence the emphasis upon the immediateness of the occlusion, and hence also the importance of considering how this necessity is to be met in war—*i.e.*, how the primary antiseptic occlusion and the other primary methods can be made practicable upon the battle-field.

In considering this point farther on, the writer shall, of course, owing to his inexperience in actual warfare, although it has fallen to his lot to test in a measure the principles whereof he speaks—isolated cases in hospital and military practice—disclaim any spirit of dictation, but shall give what he has learned from a study of the subject as handled especially by the German military surgeons who figured prominently in recent European campaigns. In this second method, not only should the occlusion be immediate with regard to the lapse of time, but also in respect to affording neither time nor place for practices of probing, digital examination, extraction or attempt at extraction of bullet, disinfection, or drainage. There exist only these indications: to cleanse antiseptically the superficies in the immediate vicinity of the wound, and at once apply an occlusive covering of antiseptic material. To make any given case authentic, as having been treated under the second method, it may not be immaterial, at any rate not undesirable, to state in the report of the case the negative assertion that no internal examination of the wound was made, either with the sound or with the finger.

The best-informed surgeons found it difficult to impress the paramount necessity of this simple precaution upon their associates in the war, so that these latter should sufficiently realize its imperativeness, and hence arose the limited opportunities of getting hold of the cases sufficiently early, *i.e.*, before a surgeon or assistant, or meddlesome "sanitar" had internally examined the wound-track with the finger, or its extension the probe; thus laying open a hitherto practically subcutaneous injury, infecting a hitherto non-infected wound, and thereby precluding its occlusion.

In such an instance, the golden hour for its occlusion

having passed, the virtually subcutaneous and surgically clean wound of an hour ago, so well adapted for healing *per scab*, with its comparative immunity from the destructive processes to which open wounds lay themselves liable, must be treated as an open, gaping, and if not a visibly contaminated, at least a surgically unclean wound—such a one as must needs be disinfected and drained, *i.e.*, treated according to the third method of treatment of gunshot wounds, namely, primary antiseptic disinfection and drainage.

Although primary drainage is not the worst accident that can befall a gunshot wound, and although probably it takes precedence of all secondary methods (which point will be further on considered), yet let it be remembered that experienced military surgeons abroad (Esmarch, Langenbeck, Reyher) and at home give their firm advocacy to the primary occlusion in all cases to which it is applicable, as the best method, and consider that the cases to which it could be rationally applied would largely increase if surgeons would hold inviolate the negative precepts (unless the indication to the contrary were clear) of no probing, no digital examination, no extraction of or "search after" the bullet, etc.

Sir Wm. McCormac, in his visit to this country a short time ago, took occasion in a lecture delivered, by invitation from the Professor of Surgery, before the students of Bellevue Hospital Medical College, to caution them against the indiscriminate use of the probe or finger in gunshot wounds, affirming the soundness of the modern views and precepts upon the treatment of gunshot wounds, given by such eminent military surgeons as Esmarch and Reyher, "not to do any damage," and to treat in all respects sparingly, etc.

To excessively and painfully diagnosticate a gunshot wound, for instance, of the knee-joint, is as harmful and unwarranted a procedure as percussion of a chest of one sinking with pneumonia for the purpose of locating more definitely a patch of hepatized lung. It is fairer that our vanity should forego the exhibit of our diagnostic acumen than compromise, yea, jeopardize, the chances of our patient's recovery. It is better that our patient recover his joint without anchylosis, though he may be ignorant of its involvement, than that he should go maimed through life, through his surgeon's excessive diagnostic inquisitiveness.

3A. *Primary antiseptic drainage, i.e.*, the scrupulous disinfection of a wound visibly contaminated or specifically or septically infected, from any cause whatsoever (surgeon's probe or finger, particles of dust or foul air, pieces of clothing or other foreign bodies, exclusive of the bullet, which is usually innocuous, and if it cause disturbance can be removed later, when the dangers of septic phlegmon, erysipelas, pyæmia, etc., are past), and the removal of all irritating secretions the very moment they are formed through some provision for drainage, to make which complete it may be necessary to resort to extensive incision—cuts and partial resections, etc.

The primary drainage is intended to prevent the accession of inflammation, to dispel all apprehension of pus formation, which process can serve no useful purpose, but drains off, in its ichorous secretion, the highly vitalized organic tissue elements intended for the constructive processes of wound repair. Esmarch formulates his practice in infected wounds thus: "An early antisepsis, a radical disinfection, and an infrequent repetition of the cleansing and dressings."

Referring[1] to Esmarch's permanent aseptic dressing the *Medical and Surgical Reporter* states that "Esmarch has carried asepticism to its logical conclusion, maintaining that if a wound is once well and completely dressed antiseptically, it should heal without much further attention, and that changing the dressings is merely incurring new dangers needlessly." And Lister, speaking of this "Dauer Verband," characterizes the accumulation beneath it of bloody serum and foul secretions of a week's standing as "surgically clean because it is aseptic," and the "æsthetically cleanly water" he declares to be "surgically dirty because it contains elements that give rise to septic changes in wounds."

The drainage, then, in the third method, should coincide with the formation of the first wound secretions, which are at that time, to be sure, not septic or virulent, but physiological in their vital properties and composition, but very prone to take on putrefactive decomposition, and if no provision is made for their seasonable conduction from the wound, decompose and set up irritation and consequent inflammation.

In this sense is the drainage primary, and, when done with antiseptic precautions, constitutes the third method, which, however admirable it may be in its operation and results, is not comparable with the simplicity of application and the beautiful results obtainable by the preceding method.

3B. *Primary resections and amputations;* surgical interferences which take place immediately that the injury is done, and have for their object the securing of better drainage or the conservation of a limb or other body member and the preservation of its proper function, or the saving of life at the cost of a limb from the amputation—cut which partakes of the character of a large incision—cut in that it affords ample drainage for the secretions.

4. *Intermediary drainage, resections, and amputations;* operative measures introduced after the acute stage has passed and before the approach of the suppurative stage. These operations are usually done upon infiltrated parts, and, like secondary methods, should be followed by the open treatment of the wound or stump, so as to make ample provision for the profuse discharges from the infected and infiltrated tissues.

5. *Secondary drainage, resections, and amputations;* surgical procedures introduced after the setting in of suppurative action.

The latter partake of the character of a forlorn hope, and awaken in one's mind the consciousness of a lost or unheeded opportunity. The relative merits of the primary and secondary drainage still remain to be considered in subsequent paragraphs.

To recapitulate, now, the several methods of treatment of gunshot wounds: 1, Non-antiseptic occlusion; 2, primary antiseptic occlusion; 3, primary antiseptic drainage, resections, and amputations; 4, intermediary antiseptic drainage, resections, and amputations; 5, secondary antiseptic drainage, resections, and amputations. We may now go on to consider the subject of early *versus* late antisepsis in military practice.

Given, a gunshot wound that is certainly infected and hence cannot be occluded, but must be disinfected and drained, the query arises, Does experience teach that an early antisepsis is obligatory or optional? If optional, *i.e.*, if secondary antisepsis will afford us as good results as primary, then the problem, how to make primary methods practicable upon the battle-field need not present itself to our minds for solution. It were then already solved by its abnegation as not being necessary, and hence to be dispensed with, and late methods of antisepsis substituted therefor.

Upon this point, strangely enough, the experience of the Prussian military surgeon, Oberstabsarzt Hahn, in the Roumanian war, is at variance with those of Reyher and Bergmann.

Hahn declares that he experienced a complete antisepsis in cases admitting of a radical disinfection and subsequent complete drainage, even in patients wounded at Plevna and Ratowa, who had to pass through a three to five days' transportation. He further declares that under his care he did not perceive a single case of septicæmia, pyæmia, gangrene, or erysipelas.[1]

[1] Braithwaite's Retrospect.

[1] Fischer: Kriegschirurgie.

Von Scheven distinctly states that the efficacy of an antisepsis depends less upon the interval of time elapsing between the receipt of the injury and the disinfection than upon the configuration of the wound, *i.e.*, whether or not the wound will permit of a thorough disinfection and subsequent effective drainage. His experience seems corroborated by the testimony of other Prussian surgeons, who claim to have observed an antisepsis in cases not coming under a radical antiseptic disinfection until after the first week subsequent to receipt of injury. According to Reyher's experience, an early antisepsis seemed imperative, and the problem for military surgery seemed to be, how could a primary (early) antiseptic *régime* be made practicable upon the battle field, "seeing that an engagement does not usually terminate before nightfall, that the wounded must be gathered in and await their turn, and in order that the antiseptic disinfection be made radical and effective, it must be done with system and care." [1]

Naturally enough, the success of Hahn and Von Scheven with a late antisepsis raised high hopes in the expectations of military surgeons, and would, indeed, have inaugurated a happy era in war surgical practice, had not their experiences been set over against those of two such eminent surgeons as Reyher and Bergmann. The statistics of these latter two show a large per cent. of recoveries in early over late antiseptically treated shot-wounds of all kinds, and emphasize the importance and necessity of an early antisepsis. On the other hand, Hahn asserts that an early antisepsis is not imperative; but a late disinfection, if it be done with scrupulous care, so that it shall be radical, will prove equally efficacious.

This is a startling assertion in the face of facts and figures given us by Reyher in his Turko-Russian campaign; and Fischer does not attempt to reconcile or explain such glaring differences from equally reliable sources.

I cannot withhold Reyher's tables, which speak with no uncertain sounds as to the marked precedence of primary over secondary methods of wound-treatment, both in joint-shot injuries and shot fractures. I, therefore, insert his tables Nos. xi., xii., xiv., and xv.[2]

TABLE XI.—*Seventy-eight Joint-shot Injuries Treated by Secondary Antisepsis.—Conservative-expectant Therapy.*

	Healing under the scab carried out.			Drainage after an unsuccessful attempt at healing under the scab. This secondary drainage was carried out.			Intermediary and secondary resection after unsuccessful secondary drainage.			Intermediary and secondary amputation after unsuccessful secondary drainage.			Intermediary and secondary amputation after unsuccessful resection.			Total of all joint-shot injuries treated by secondary antisepsis.

* In these, two were complicated through other injuries (shot injury of lungs and spinal marrow).

Probably the weight of authority declares in favor of an early antisepsis. At any rate, it was instructive to observe how small a per cent., in Reyher's experience, of those who died under primary antisepsis, as compared with those who died under secondary antisepsis, succumbed to pyæmia and septic phlegmon.

In favor of an early antisepsis, I may find an argument in some facts communicated to me in a letter by Dr. Adler, who furnished me with an extract from a communication by Professor G. C. Bon, entitled, "Properties of Antiseptic Remedies and the Value of the Products of Decomposition."

The salient points *apropos* to our present argument were: 1. That no parallelism was observed between the power to prevent the commencement of a decomposition and that of arresting the same after it had once begun. Alcohol and carbolic acid, which are so efficient conservatives, possess but a small influence over a decomposition once commenced; and as carbolic acid has such an extraordinary success in surgical practice, this effect must be ascribed solely to its power of preventing decomposition. Professor Bon concludes from his experiments that carbolic acid is a powerful preventive to decomposition, but a weak germicide. Indeed, he regards carbolic acid as a substance very much adapted for a long preservation of bacteria (!!!).

He has in his possession solutions of carbolic acid, four months old, which contains an abundance of bacteria. He found that if 10 ctm. of a normal solution—a watery solution containing one-tenth of its weight of chopped meat was accepted as a normal liquid—be mixed with fifty or a hundred centimetres of a saturated solution of carbolic acid, it would result as follows: Most of the bacteria would lose their movability, while the smaller ones would remain alive and would be fruitful.

2. No parallelism exists between the disinfecting power of an antiseptic and its action upon bacteria.

Professor Bon found permanganate of potassium—one of the most excellent disinfectants—to have no effect upon micro organisms, while alcohol, which retards the development of microbes for a considerable length of time, acts disinfectantly only in a very slight degree upon putrescent substances.

3. The power of an antiseptic becomes weaker the further decomposition has advanced. For example, should a watery solution containing one-tenth of its weight of chopped meat be accepted as a normal solution, a putrid odor will develop in the first days of the decomposition, which smell can then be removed by small quantities of an antiseptic; if, however, the putrid odor is permitted to develop further, a proportionally large quantity of an antiseptic is required to dispel it.

Now, if the virtue of carbolic acid, as the representative of a class, lies in its power to prevent decomposition, it would seem reasonable to infer that to insure its full benefit it should be applied early—primary disinfection, *i.e.*, before the putrid stage has set in, the stage of bacterial development.

Do not, then, these experimental data of Bon in the laboratory tend to confirm the practical results of Reyher on the battle-field, and incline one to favor the application of antiseptic treatment at the earliest practicable moment.

The scientific labors of Dr. George M. Sternberg, surgeon U. S. Army, in this direction, and their practical teachings, are sufficiently well known to American readers to need no reference here.

Assuming, then, what is altogether probable, that better results are brought about in war surgical practice, through an early, *i.e.*, primary antiseptic *régime* than through a late antiseptic treatment, the question of the practicability of primary methods in military practice may well come up for consideration.

In order that these methods shall, in actual warfare, be strictly primary, it is essential that provision be made so that these methods can be applied upon the battle-field.

Recognition must there and then be taken of the principles of antisepsis, and nothing should be done contrary to those principles, either through the ignorance or meddlesomeness of assistants or negligence or want of information on the part of the surgeons. The former should be instructed, so far at least, in the underlying principles of antisepsis, that they shall do no damage, for example, by roughly handling a compound penetrating fracture in transportation, so that the wound be made to gape, and by a suction force draw air within, and by pumping movements cause it to infiltrate the interstitial tissues; or by rough manipulations set up a profuse primary hemorrhage in such a fracture, making it necessary for the surgeon to go into the depth of the wound and ligate, and hence causing the wound to become unfit for occlusion, to which it was till then in every way suitable.

Or again, the assistant may act contrary to the principle of antisepsis by examining the wound internally with probe or finger, before the most experienced and best-informed surgeons shall decide that the wound was previously infected, and was from the moment of receipt of injury an unclean wound, as, for instance, in large shell-wounds which from the very nature of the injury are open and infected from the start.

Although (thanks to the rifles and projectiles of modern warfare) a large number of wounds can be readily disposed of without much loss of time under the treatment by primary antiseptic occlusion, which is so simple in its application that unskilful hands may apply it, if only guided by the principles of antisepsis, yet there remain over a considerable number of wounds which demand at the hands of the surgeons immediate antiseptic cleansing, disinfection, and drainage, and not a few that require primary resections and primary amputations.

How shall all this be done with system and care upon the battle-field? How was it brought about, as Reyher asserts, that he "was enabled to carry out in his flying hospital a treatment fundamentally different from that possible in the Russian military hospitals?" He tells us that under the protection of the Caucasian Committee of the Society of the Red Cross, a field hospital of one hundred and fifty beds, and a flying hospital of forty beds were placed under his direction. These hospitals were supplied with all apparatuses and materials necessary for the complete carrying out of the essential principles of

Listerism, and attached to each was a surgical staff thoroughly informed in, and in accord with, the principles of antisepsis, and also a corps of nurses (Sisters) trained at the Dorpat clinic, and hence intimate with the antiseptic methods of wound-dressing.

Translating from his pamphlet: "The flying hospital, with the headquarters, attended the movements of the operations directed against Kars; the field hospital followed the same at a distance of 20 to 40 kilometres (1¼ to 2½ miles). Thus it was in the position, in connection with the division hospitals, to possess every time, at the main dressing-place, my own operation-tent, and to be able to carry out in it everything after Listerian principles. As the flying hospital further possessed its own transport train of two-wheeled and large ambulances, it was further possible for me to direct the cases taken up on the dressing-ground, and cared for after Lister, with my own ambulances and my own *personnel* into the flying hospital, and thence, after a few days' rest, into the field hospital. In this way were assured to me the first dressing, and a continuation of observation and treatment."

Such paramount importance does Reyher attach to this "continuity of observation and of treatment," that he considers it advisable that the same medical *personnel* should be active in the field hospitals as attended the wounded upon the first dressing-place. To this end he would have the rear-hospitals follow constantly in turn the movements of the army, in lieu of transporting the wounded through a series of hospitals to the rear-hospitals, making discontinuous the observation and treatment.

How far this may be practicable, he leaves to the administrative to determine.

Again quoting from his pamphlet: "Thus only will be assured to the observation the continuity so extremely important to the welfare of the treatment, and thus only will be afforded to the surgeon the possibility of perfecting himself in the surgery of war. Of the transient impressions on the battle-field and at the principal dressing-place, there remains to the surgeon only the picture of the severity of the injuries and their multiplicity; he sees and learns there nothing of the most important thing, the course of the wound and the process of healing."

In another paragraph, speaking of the greater length of time required for the antiseptic care of wounds over non-antiseptic therapy, and admitting that an hour's time or more may be taken up in the radical disinfection of a single knee-joint, he concludes in these words: "But if one considers that the majority of shot-fractures from small arms, and shot-wounds of the soft parts will require only an antiseptic occlusive dressing, which any voluntary assistant can apply; that the application of the tin-splints (Volkmann's), cut and on hand, can be done by any surgical assistant; that ligation of arteries is very seldom indicated upon the dressing-place, and then even is an operation consuming the least time, thus then only the primary amputations indicated through tearing apart by large shot, and the joint-shot injuries and fractures which call for a primary disinfection or resection, remain over for the activity of the operating surgeons. The number of these, to be sure, can be very large if each of the injuries has already been probed or examined with the finger before it comes under treatment at the principal dressing-place. But it will certainly not be large if from the battle-field up to the principal dressing-place the surgical activity shall confine itself to provisionary measures, and as wide a play as possible be given the occlusive method upon the dressing place.

We come now, naturally enough, to consider the merits of the several methods and their adaptation to uncomplicated gunshot wounds of the soft parts, and to such wounds, complicated with fracture, simple and compound, or complicated with injury to the blood-vessels, or by lodgement of foreign materials visible to the eye, causing palpable infection, or by microbes macroscopically invisible, but, nevertheless, surely infectious, etc., and, further, to gun-shot wounds of the joints and the large body cavities.

It may justly be premised that no method is so universally applicable to the generality of gun-shot wounds, in civil or military practice, or so fruitful in good results as to preservation of life, limb, or function, or so favored in immunity from untoward results and accidents of surgical repair, as primary antiseptic occlusion.

This method, when applicable, is superior to all others, because it is the simplest, the least annoying to the wound, the patient, and the surgeon; it prevents swelling and pain, it does not interfere with the appetite, for the secretions are not perverted, and the bowels locked up by morphine for relief of pain; it heals in the shortest possible time, it is attended with the minimum rise of temperature, and requires so very little after-care.

Apropos, the writer could mention one case in particular, treated by him and reported to THE MEDICAL RECORD of December 2, 1882, of a very serious gun-shot wound from a cylindro-conoidal bullet of .45 calibre, penetrating the thorax beneath the clavicle in front, and making its exit through the shoulder-blade, causing the pulsations of the subclavian artery to become visible to the surgeon's eye, and lacerating the rich plexuses of veins and lymphatics that abound in the cervical region. This wound-track, five inches in length, healed almost its entire length in seven days under a single permanent aseptic dressing.

It sometimes requires a nice effort of discrimination to decide, in the case of a wound that stands on the border line between infection and non-infection, whether or not it is adapted to the occlusive treatment. But even in these doubtful cases the possible formation of pus after occlusion could be determined by the thermometer and the pulse-beat before any danger should arise to the patient, and drainage could then be instituted.

By observation in an Indian country, and upon inquiry from commissioned officers of companies of Indian scouts, I have learned that the Indian when shot allows the fibrin of the blood to occlude the stomæ of his wound, while he applies a cooling lotion or some mother earth to the injured member, or places alongside of the limb an innocent twig or branch from the cotton-wood, and then proceeds with his incantations and other harmless ceremonies, in the meantime the wound-track knitting under a primary occlusive covering.

One may say the splendid result obtained is due to the Indian's magnificent physique, but the writer has obtained similar results in soldiers wounded after being greatly fatigued by following up trails in an Indian country, and who were four days' march from base of supplies, without suitable food or medication, with absolutely nothing but the application of the all-potent principle of primary antiseptic occlusion, and a splint of plaster-of-Paris to steady a compound fracture, which had to be conveyed for ninety miles in travois over a country that seemed made up of the odds and ends of creation. Here was a compound gunshot fracture of the humerus, an injury sufficiently ominous under the most favorable surroundings, not to mention the deprivations that beset this individual case; but the early occlusion robbed it of its serious omens by rendering it subcutaneous by an artificial skin, and thus transforming it into a simple fracture.

A wound so treated does not invoke the trinity of evils of many non-occluded wounds, namely, suppuration, granulation, and cicatrization. The robustness of the constitution is not so pertinent a factor in a simple fracture or in a compound one, that can be rendered subcutaneous, as in open wounds that drain away highly vitalized fluids; hence, in a weak constitution, the occlusive method is doubly to be desired.

I have a time or two congratulated a patient on his rapid recovery—all honor due to the occlusive method, which shut out the germs that would have tried a robust

constitution and might have caused a weak one to succumb—but invariably I have met with the self complaisant response: "Oh, doctor, I have such a good constitution, or I should not have recovered." Your constitution to the dogs! Aren't you an inveterate tobacco-user, haven't you had the clap now for the third time, and were you not under treatment for stricture at my hands, and bladder complications, when you were shot down!

I cannot forbear to translate here a few paragraphs bearing upon this most important method of treatment of gunshot wounds—the antiseptic occlusive, by which in doing so little so much is accomplished—from the admirable pamphlet of Karl Reyher, already quoted from:

"Where the conditions are suitable for healing *per scab*, it is of essential importance that the internal examination of the shot-canal be omitted, *i.e.*, that the already closed wound-canal be not again opened, and that its opening in the skin be occluded as quickly as possible. It is of only relative and subordinate value whether one permit the blood in the skin wound to dry up without a dressing, and thus allow the blood-crust—the blood-scab of Hunter—to become the antiseptic preventive against infection from without, or whether one, in order to hasten the drying up, make use of a particular agent, as clean charpie, wool, antiseptic gauze, or hæmostatic wadding; or, finally, whether one cover with protective the small coagulum filling the skin wound, and thereby assign to this the rôle of a scab. Since, however, the occlusion through the protective is not a complete one, as the coagulum lying underneath, for the time being, remains moist, the filling around with antiseptic materials must follow for the perfect protection against decomposition. The essential thing in all these different methods of treatment under the scab consists in the not-probing, in the not-draining, and in the occlusion of the skin wound, and the motive thereto lies in the principle of antisepsis."

And Reyher quotes from von Langenbeck's famous address, "Upon the Shot-fractures of Joints and their Treatment," as follows: "It one intends to adopt the conservative treatment of knee-joint injuries he cannot be too urgently warned against probing of the shot openings with the sound or finger."

Reyher gives his firm advocacy for occlusion in penetrating gunshot wounds of the thorax, and once applied the method successfully in a case of penetrating pistol-shot wound of the abdomen upon the duelling ground, in which the ball lodged in the parietes.

The writer has seen a case of penetrating pistol-shot wound of the lung and pericardium, complicated with pneumonia and pericarditis, recover under an occlusive dressing, *i.e.*, without drainage. Reyher declares that the beautiful results of the occlusive method of treatment of penetrating gunshot wounds of the chest are sufficiently well known, making it (at least) a justifiable procedure.

The method of hermetically sealing gunshot wounds of the chest was given a trial in the War of the Rebellion by Assistant Surgeon Howard, United States Army. It differs in some particulars from primary antiseptic occlusion, in which there is no paring or suturing or disturbance of the blood-crust. If the aspersions of Surgeon Derby, U.S.V., published in the *Boston Medical and Surgical Journal*,[1] are intended to apply alike to "hermetically sealing" and "primary antiseptic occlusion," the writer cannot free himself of the conviction that the language is too severe and the condemnation too sweeping. The language referred to appears in the following paragraph: "In July, 1864, it came in my way to see six cases at one time treated in this manner (hermetic sealing) at the field-hospital of the Eighteenth Army Corps before Petersburg. All six promptly perished. The verdict of army surgeons who have tried this method, I think, is unanimous. Can we not then be done with it—banish it from our books of military surgery, and let it rest with the multitude of exploded theories which have preceded it? A writer in the London *Lancet* some time ago clearly showed that it was unphilosophical. Experience has proved it fatal."

There is a class of gunshot wounds that may be considered unique, and in which, according to the teachings of the lamented J. Marion Sims and many surgeons now living, there is no time for folded hands, and from which cases operative surgery may snatch some of its brightest laurels. I refer, of course, to gunshot wounds of the abdomen. But we must not be unmindful here that we are treading upon hotly contested ground, and that many experienced surgeons assume in these cases an attitude of "expectancy."

A localized hypersecretion is the inevitable and legitimate result of the infliction of any wound. This serous transudation, when it takes place within the peritoneal cavity of the abdomen, seems for some reason more virulent than when it occurs elsewhere, and, according to the experience of J. Marion Sims, readily induces septicæmia and kills through septic blood-poisoning, and not from peritonitis. It fell to the writer's lot to take down notes in a case of post-mortem from gunshot wound of the abdomen, some five years ago, and he distinctly remembers of jotting down the fact, which seemed to him then foreign and irrelative, that the abdominal cavity contained a pint of bloody serum. Death was ascribed to peritonitis. We had not then learned that peritonitis does not kill in the rule; that the exudation of lymph was simply reparative or conservative.

In case, then, of a gunshot wound of the abdomen, especially when septic infection threatens, it would be held by many to be good surgery and a justifiable procedure—perhaps an imperative duty—to open the abdominal cavity, repair any damage done to its contents, and then thoroughly disinfect the cavity and close its parietes.

To the *Medical News* of February 14, 1885, Dr. William T. Bull contributed an article on "A Case of Gunshot Wound of the Intestines, treated Successfully by Laparotomy with Suture of the Intestines," which, together with its discussion before the New York Surgical Society, was full of suggestion and instruction.

It remains to consider the permissibility or non-permissibility of the occlusive method to shot wounds complicated with injury to a blood-vessel. If, in such a case, the hemorrhage is excessive, the blood spirting forth in a full stream, the only indication that exists is, of course, to go down into the wound and ligate and then disinfect and drain. But experience has established the clinical fact that a blood-vessel of large size may be seriously injured by a bullet in its course, and still give rise to no symptoms of hemorrhage, healing taking place per scab, and the diagnosis verified by post-mortem, death having resulted from some cause other than injury to the vessel.

In the writer's own case of gunshot wound of the chest (referred to in preceding paragraphs), the bullet passing just below the subclavian artery and making visible its pulsations, the possibility at least existed that, had the wound not been occluded, but disinfected and drained, the possibly injured coat of the artery might not have been able to recover itself, and by a process corresponding to caries in bone might have lost its vitality and induced secondary hemorrhage. Had such taken place in spite of occlusion, a key and assistant were at hand for employing instant compression of the subclavian behind the clavicle.

One more word for occlusion in gunshot wounds of the joints. The report already quoted from of the Surgical Committee of one of the State Societies contained also the emphatic but erroneous statement that "penetrating gunshot wounds of joints are invariably attended with suppuration." And surely we can say "almost invariably" when the surgeon has had recourse to the probe or finger, or bullet-forceps, but seldom when his

[1] Medical and Surgical History of the War of the Rebellion.

guiding precept has been[1] "*sans* probe, sound, or finger; *sans* extraction of bullet; *sans* drainage; *sans* everything except disinfection of the exterior of the wound, and occlusion of the same," at the earliest practicable moment after its infliction. By this method Reyher obtained beautiful results in penetrating gunshot wounds of the knee-joint (with projectile wedged into the condyle) preserving the function and mobility of the joint.

Much discredit, the writer fears, is brought upon this most admirable method of wound treatment—the primary antiseptic occlusive—by its misapplication to wounds manifestly unsuited for occlusion, by reason of infection, it may be, from foreign bodies, or from having previously been internally examined, or possibly from the nature and configuration of the wound itself.

If the wound is not a fresh and clean one; if the canal has not been shut off from the external world by shifting of the soft parts immediately that the injury took place; or if the wound-track, that has been virtually occluded from the start, is laid open now for the first time by the surgeon's examining finger; or if of necessity the surgeon must go into the wound for the purpose of ligating a bleeding vessel or of removing some palpable object of infection—let not such a wound be occluded. It is an open infected wound, and must be treated as such by drainage and disinfection. These should, if possible, in the interests of such wounds, be primary and radical. Here the maxim aptly applies, "What is worth doing at all is worth doing well." To insure a radical disinfection and subsequent complete drainage it may be necessary in one case to do a partial resection, in another to slit up pockets where fluids may accumulate or pus burrow, to remove splinters of bone, which, if allowed to remain, may intercept the drainage-canal, or it may be that the vitality of the parts is so threatened that drainage must be provided for conducting off large quantities of effete material when nothing less than the large amputation-cut itself may suffice.

The thoroughness of our efforts with which we should strive after complete drainage of infected gunshot wounds is exemplified in a case of compound fracture of the arm, with shattering to pieces of the os humeri from its surgical neck down to its lower epiphysis, causing the arm, to dangle by the side, the soft parts forming a sac in which the crushed fragments could be moved to and fro; other long spiculæ projecting from the patulous shot entrance.

The surgical procedure is thus related by Reyher:

"To the not little surprise of the bystanders I divided the soft parts of the arm in the sulcus of the long head of the biceps muscle, from the shot entrance down to the epiphysis of the elbow-joint, and thus laid bare the shot canal and fracture in its whole length. The wound surface, when the margins of the incision were spread out, was enormously great. In it lay, like a carpet, the separate fragments adherent to the periosteum. I took away those that were entirely released, I removed the blood from every nook and corner; drainage, antiseptic dressing, etc., all on the dressing-place. Healing complete in five weeks."

In gunshot wounds of the thigh where the canal of the projectile lay obliquely, and was hence of considerable length, the almost unsurmountable obstacles against securing adequate facilities for complete drainage quite discouraged Reyher in his attempt to secure through disinfection and drainage an aseptic course to such wounds. Hence his earnest protest and caution against the too ready resort to internal examination of these gunshot wounds of the thigh, when possibly by a judicious conservatism healing may be brought about under an occluding scab—so utterly bad is the prognosis in open shot wounds of the thigh.

On anatomical grounds alone the disinfection of joints and of epiphyseal fractures is much easier of accomplishment than of shot wounds of the soft parts or of the diaphysis of a bone. In the two latter cases the amount of blood poured out is absolutely greater than in the two former instances, owing to the relatively greater vascularity of the bellies of muscles and the shafts of bone through which the nutrient artery runs, than the almost bloodless condition of the tendons and component parts of a joint. Not only so, but—what is of more practical importance—the effused blood in a joint cavity is bounded and restricted by definite limits—the joint capsule; while in a diaphyseal fracture the blood may widely infiltrate the intercellular tissues and wallow beneath and among the muscular planes. How simple to puncture and evacuate the contents of a joint capsule, how many and what extended incisions may be required to cleanse a fracture of a diaphysis!

Seeing, then, that extensive incisions or a resection, or possibly an amputation, may be necessary to insure perfect drainage in an open gunshot wound, it is the duty of the surgeon to have in readiness instruments and dressings suitable for these operations, and on hand at the time the internal examination of a given wound is decided upon, so that these operations may proceed forthwith, immediately that they are found to be indicated, else the examination shall be to no purpose and may prove hurtful rather than beneficial. The partial resection of healthy and uninjured epiphyses of joints may have to be done, and how this can be effected so as to best conduce to drainage, can only be learned from an intimate acquaintance with the anatomical construction of each joint severally.

The clinical and didatic teaching of the subject of handling gunshot wounds—a subject of so great and preponderating interest and importance—should be afforded greater prominence in the curricula of the medical schools of our own country.

OBSERVATIONS ON SOME OF THE MORE UNCOMMON SYMPTOMS AND COMPLICATIONS OF MALARIA.[1]

By LEONARD WEBER, M.D.,

NEW YORK.

In offering the following remarks the writer is well aware that they are far from covering the entire subject of the complications and irregularities of malarial disease. He simply wishes to put on record a series of cases occurring in the course of his practice, which may serve to illustrate the subject denoted by the title of this paper.

1. *Hemorrhages.*—Epistaxis, more or less copious, I have seen in five cases of febris intermittens. It took place in the sweating stage and during the intervals of the malarial paroxysms, and was, in three of the cases, severe enough to require plugging of the nares. Frequent relapses were the rule until the fever was under control and the patient's general condition improved by tonics and change of air.

Of three cases of hæmaturia of renal origin which I have seen coming on with the paroxysm of intermittens, I will give the history of the following as particularly striking:

Major P——, from Georgia, aged fifty-eight, of apparently good constiution, and not, as far as he knew, suffering from malaria before he left home, came to this city in August, 1882. While here he would join his friends and go quite frequently to the horse races on Coney Island. In the afternoon of September 2d I was sent for to see him at his hotel. I found him free of fever, but looking pale, feeling weak, and complaining of pains in the hypochondriac and lumbar regions. During the preceding night he had passed at least a pint, he thought, of fluid blood with his urine, and had voided some more a few hours before I saw him. He had never done so before,

[1] Read before the German Medico-Chirurgical Society.

though he felt somewhat chilly the day before, he does not remember having had malaria for many years.

General examination and exploration of bladder negative. I had the patient put to bed, and prescribed a solution of gallic acid. Saw him again the next morning early. He had passed some more blood during the night, and had now a temperature of 102.5° F., head- and back-ache, etc. At noon he perspired freely, and his temperature became normal soon after. An acid solution of 3 ss. of quinine was administered in the course of the morning, and neither fever nor hemorrhage returned. The quinine was continued in smaller doses, and a week later the patient was able to return to his home in apparently good health.

2. *Hemorrhagic nephritis.*—Of the hemorrhagic form of nephritis in the course of and through the influence of malaria, I have seen but two cases, both in adults. Neither of them had any symptoms of renal disease; they contracted malaria before, but showed the unmistakable symptoms of hemorrhagic nephritis soon after.

In neither case was there much difficulty in eliminating the malarial element by the proper remedies and change of air. Nevertheless, the subacute nephritis passed into a chronic form of Bright's disease. Albumen and casts in small numbers can be found in the urine, and slight hæmaturia occurs from time to time. The man's case is now of three, the woman's of six years' standing. The late Professor Bartels, in "Ziemssen's Cyclopædia," lays much stress upon this grave complication or sequela of malarial disease.

In this connection I may also relate two cases of *acute purulent urethritis*, first coming on together with the malarial attacks in two young men. Both patients presented symptoms of neurasthenia of sexual origin, but were entirely free from gonorrhœal infection. The urethral discharge was painful and accompanied by frequent micturition, and gave them more uneasiness and discomfort than the malarial fever. Mild injections of sulpho-carbolate of zinc did no good, but quinine and Warburg tincture cured them of both evils. Of this rare freak of malaria, Bartels also mentions one or two instances.

3. *Malarial hæmatemesis.*—Of hæmatemesis, in all probability independent of gastric ulcer, I have seen one case. Mrs. W——, about forty-five years of age, stout, but strong and active, had been repeatedly under my treatment for recurrent attacks of parametritis of puerperal origin; her stomach had always been in good condition. Four years since, during her convalescence from one of these attacks, she was taken with intermittent fever, and in the algid state of one of the paroxysms vomited about six ounces of dark fluid blood, intermingled with some soft coagula. This was immediately followed by a dangerous collapse, which it took some hours to overcome by hypodermics of brandy and other remedies. Sulphate of chinin and bromide of sodium (āā gr. v.) given in wafers every two hours until thirty grains of each had been taken, prevented a relapse of the intermittens and the hæmatemesis as well. The patient had another attack of parametritis last year, associated again with malaria, but no bleeding occurred at that time.

I have the record also of two cases of intermittens, concerning young and somewhat delicate women, complicated by repeated paroxysms of rather severe hæmatemesis, which yielded to quinine only. In neither case had any previous symptoms of ulcer or other organic lesion of the stomach been noted.

Intestinal catarrh, characterized by frequent watery, slimy, sometimes bloody stools, and constituting the principal feature in certain cases of subacute malaria, I have seen quite often in children and young persons of both sexes. Of late I have given in such cases quinine and ipecac during the day, and from ten to twenty grains of salicylic acid immediately after meals, prescribing a careful regime as to diet, etc., and have had better success in relieving the patients rapidly, and often permanently, than by giving quinine alone or quinine or opiates, as I did in former years.

4. *Apneumatosis, i.e.*, more or less complete collapse of limited portions of pulmonary tissue in the course of bronchial catarrh, I have seen to accompany the acute or subacute forms of malaria in upward of thirty cases, concerning mainly children and adolescents. The clinical picture of this condition, one example of which will serve as an illustration of all the others, may be described about as follows: We are treating a case of malaria in a child of neither robust nor exactly delicate condition; the patient is better of the fever, but troubled with a slight cough accompanied by little, if any, expectoration; no constitutional disturbance, none of the signs of capillary bronchitis or pneumonia are present; yet we examine the thorax carefully, and find pretty well marked bronchial respiration, posteriorly, above and below the spina scapulæ, on one or both sides. The percutory sounds are not in harmony with the auscultatory phenomena; they may be somewhat dull, but are more often only shorter, of higher pitch, and less full than the normal non-tympanitic sounds. The patient has no dyspnœa. After being relieved of malaria and improved in general health, the bronchial breathing diminished in force and extent rapidly, or more often slowly, and finally gives place to the normal respiratory sounds. It may be two, three, four, and more weeks before this is accomplished, but in every case of this kind—uncomplicated by organic disease—I have observed complete recovery as the final result. Not until I had read a short article on apneumatosis in general, in "Reynolds' Encyclopædia," could I get rid of the bugbear of some alveolar exudation or peribronchial inflammation in trying to understand the above disturbance of the respiratory organs. It is simply a mechanical process, the inspiratory current not being strong enough in such patients to overcome the obstruction caused by the presence of viscid catarrhal secretion in the smaller bronchi, the alveolar residual air becomes gradually exhausted, and a certain area of lung tissue is rendered apneumatic, and more or less completely so.

With the recurrence of respiratory vigor and the removal of the liquefied catarrhal secretions, the collapsed lung tissues are gradually reinflated and brought back to the normal condition. That apneumatosis may occur in the course of constitutional disturbances other than the malarial, I do not deny; I simply want to put it on record that I have seen what I described much more often in the course of that disease than of any other. In the treatment of it, after careful elimination of the malarial element by chinin and stimulants, I have found the tepid half-bath, with cool affusions of thorax, lung gymnastics, fresh air, and tonics containing iron, bark, and strychnia the most serviceable remedies to facilitate recovery.

5. *Sexual disturbances in women.*—With reference to disturbances of the reproductive system in women affected by malaria, I have seen abortion directly traceable to that cause several times, and have on record the case of a strong and healthy woman, the mother of healthy children, who suffered two premature deliveries and came near losing her life by uterine hemorrhage during parturition. All other causes of miscarriage have been excluded in this case. I also remember the case of a woman suffering from intermittens going to her full time and giving birth to a female child that showed unmistakable symptoms of its mother's disease during the first two weeks of its life.

That intermittens will frequently attack lying-in women in malarial districts, and if so, produce rather formidable paroxysms, has been well shown by F. Barker and others, and is often seen by practitioners in this city and vicinity, and generally successfully treated by large doses of chinin together with the bromides.

6. *Disturbances of the cerebro-spinal system.* — The cerebro-spinal system may get into a state of asthenia in those suffering from malaria for some time, particularly

in neurotic or debilitated constitutions. I have seen several such cases of malarial neurasthenia, and found a change for one or two months to the sea or mountains—the selection to be made suitable to the individuality of the case—most beneficial in the restoration of these cases.

Intermittent neuralgias are by no means rare. They affect with preference branches of the fifth pair, particularly the supraorbital, but may also select the sciatic nerve. An efficient dose of aloes and jalap, followed by quinine, grains 15 to 20 to 30, with as much or more of bromide of potassium two or three hours before the attack, I have found most serviceable to effect a cure. A somewhat prolonged course of pil. ferr. cinchonid. et arseni will probably insure the patient against relapse.

A few cases of insanity traceable to malaria have been published, but malarial psychosis in persons free from acquired or inherited neurotic disposition is rare. In this connection I have the history of the case of Henry R——, aged forty, German, married, plumber, twenty years in the United States, resident of Hudson City, N. J., for fifteen years. No hereditary taint, no acquired disposition to cerebral disease by trauma or alcoholism or otherwise was made out; both his parents alive and well, his sisters and brothers also. He contracted intermittens in 1878, suffered frequent relapses, and began to show symptoms of acute insanity about January 1, 1882; became maniacal, and was removed to the New Jersey State Asylum, where he died on January 24, 1882.

25 West Forty-sixth Street.

Progress of Medical Science.

Abscess of the Abdominal Wall, containing the Rib of a Rabbit, healing without Intestinal Fistula.—Dr. Jagot reports (*Le Progrès Médical*) that a patient came to him with two pouting fistulous openings in the left groin; there was here also an inguinal hernia. Some two years before, the patient, a baker, aged forty-seven years, was taken with cramps while at his work; this was followed by vomiting; he was confined to his bed for several months. An abscess formed in the location mentioned, was opened, but had never healed. On probing, a foreign body was felt, and with dressing-forceps two pieces of bone were removed, together six centimetres in length, which proved to be the rib of a rabbit. Patient was at the time obliged to eat his meals hurriedly. In five days the fistulæ was closed, and a complete cure followed. The hernia may have assisted in the arrest of the bone; localized peritonitis followed, abscess of the abdominal wall, etc. The fistula discharged at no time anything but pus.

Blackwater Fever.—We are indebted to French naval surgeons for almost all we know of this particular form of fever, which they describe under various names—*e.g.*, *Fièvre bilieuse melanurique*, *F. pernicieuse ictérique*, *F. bilieuse nephrorrhagique*, *F. ictrodes remittens*, etc. English writers on the diseases of tropical climates are singularly silent on the subject. Dr. Farrell, acting colonial surgeon of the Gold Coast Colony, whose pamphlet is printed for the government of the colony, gives a very good account of this fever, with cases and temperature charts. He strongly maintains its paludal or malarial origin. The peculiar clinical features of the fever are that it only attacks those already deteriorated in health. It is very often preceded by simple attacks of intermittent fever, with progressive anæmia and sallowness. The onset is invariably sudden. The quality of the vomit and urine is peculiar. The jaundice is uniformly distributed, not in patches of varying degrees of intensity; it is seen from the very first onset of the disease, and varies with the general condition. The type of accompanying fever is remittent or intermittent, even in the worst cases. The appearance of the face is dejected; the conjunctiva is yellow, but not injected. There is tenderness of the gastro-hepatic region. The pulse follows the fever. It is not contagious. In all these respects it differs from yellow fever. The urine gives no reaction of bile; but, on the contrary, the spectrum of hæmoglobin. Microscopy shows a few altered blood-corpuscles, amorphous granules, a few epithelial casts, triple phosphates, and acid urates. Heat and nitric acid give a variable proportion of albumen. Sodium chloride and acetic acid show the characteristic crystals of hæmatin. The prognosis is necessarily grave. As regards treatment, the author recommends large doses of quinine, calomel at the onset, and occasionally afterwards, in doses of from ten to twenty grains, not only for its action on the liver and as a sedative on the stomach, but as an antiseptic, which may serve to minimize the self-infection which is apt to occur in fevers of this kind.—*London Medical Record*, July 15, 1885.

Postural Method of Treating Dilatation of the Stomach.—Dr. Tytler records the case of a woman who suffered from excessive dilatation of the stomach, producing attacks of vomiting every two or three days. The author tried various remedies to give relief, but none succeeded, until he made the patient lie on her back for two hours after every meal, with a small pillow placed below the buttocks, and kept her on a diet of milk and beef-tea. The vomiting attacks soon ceased, and after a time the patient went about as usual, wearing a tight abdominal belt, and continuing the postural treatment. In the course of a few months her health was completely restored. The *rationale* of this treatment is obvious. Owing to the relaxed and flabby condition of the walls of the over-distended stomach, the food, by its weight, caused a bulging below the level of the pylorus. When the lower end of the abdomen was elevated, the contents of the stomach were brought on a level with the pylorus, and thus they passed on in the natural way.—*British Medical Journal.*

Amount of Sugar in Blood.—Dr. Otto finds arterial blood richer in sugar than venous, the total reducing agent being the same in both, so that there is a reducing agent in blood in addition to sugar. There is a marked increase in the reducing agent contained in the blood of persons under the influence of chloroform, chloral, and morphia. The blood of the child at birth contains about the same quantity of sugar as that of its mother.—*Pflüger's Archiv.*

Nocturnal Incontinence of Urine.—Dr. A. L. Ebermann, of St. Petersburg, in discussing the pathology and treatment of noctural incontinence of urine in children, insists on the necessity of a strict individualization of the cases. He divides the latter into five categories: 1. Incontinence of urine from failure of sphincter; 2. Incontinence from increase of contractile strength of the detrusor; 3. Incontinence from diminution of capacity of the bladder, which diminution results from the patient's adhering to the infantile habit of very often voiding urine; 4. Incontinence from atony or hyperextension of the bladder; 5. Incontinence from irritation of the vesical cervix by stones. The first variety of the cases may be recognized on the ground of—*a*, inability of the patient to retain urine also during daytime; and, *b*, easy penetration of a *bougie à boule* into the bladder. The second form may be determined by—*a*, powerful ejection of water injected into the bladder; and *b*, pain felt by the patient when he tries to retain urine in presence of a call for micturition. The third category is diagnosed also by means of injecting water into the bladder; when the capacity of the bladder is diminished, the viscus admits only a certain small quantity of fluid, corresponding to the usual quantity of urine voided by the patient at a time; on injection of a surplus, the fluid flows back more or less rapidly, according to the degree of pressure on the piston of the syringe. Atony of the bladder is easily recognized from the escaping of a large

quantity of urine through a catheter introduced immediately after spontaneous micturition. The fifth group of the cases is diagnosed by the sound. As to the treatment, Dr. Ebermann recommends for the first group the administration of nux vomica or strychnine, the ascending *douche* to the perinæum, and, above all, electricity in the shape of faradization, or, in obstinate cases, interrupted galvanization, the cathode being placed at the perinæum, the anode at the hypogastrium or sacrum; for the second group, belladonna in increasing doses (beginning with 6 centigrammes five or six times daily); still better, chloral, and in anæmic children solution of perchloride of iron; for the third group, exercise of the patient's control over the bladder, intravesical injection of warm water in gradually increasing quantities; for the fourth, frequent catheterization, vesical injection of water, and electrization; for the fifth, lithotomy or lithotrity.—*London Medical Record*, July 15, 1885.

Rupture of the Aorta.—Two cases of rupture of the aorta are reported in the *Bristol Medico-Chirurgical Journal*, July, 1885. The first case, recorded by Mr. A. Prichard, was that of a man, aged fifty-eight years, who, while turning round in bed in the middle of the night, felt something give way in his chest. He became sick and faint, and continued so until he was seen the next afternoon, when the vomiting was accompanied by the ejection of a thin bloody fluid. The surface of the body was cold and the patient was collapsed, yet restless, like an individual suffering from hemorrhage. Death took place the next day. At the autopsy the pericardium was found to be distended with clotted blood, and a rent was detected in the convexity of the arch of the aorta. The rupture was an inch and a quarter long. The edges of the rupture of the outer and middle coats were ragged, but the division of the inner coat was clean cut. There was no notable dilatation of the aorta, but the tissues were thin and soft, and some apparently fatty patches were seen through the lining membrane. There was no general atheroma. The heart was large and flabby, and infiltrated with fat externally. The cardiac valves were healthy. The second case, reported by Mr. Paul Bush, was that of a young postman, aged eighteen years, who had been rowing and was sitting down in the end of the boat, when his companions noticed that he looked very ill. Death took place before he could be put ashore. There was no blood in the pericardial sac. The heart weighed nearly fourteen ounces. The muscular walls, valves, and orifices appeared to be healthy. A rupture was found extending through the internal and middle coats of the aorta immediately above the anterior aortic valve. The rent appeared to start from this site and spread spirally round the aorta in an ascending direction; its entire length was equal to one complete circumference and a quarter. The fibrous coat of the great vessel had been separated from the middle coat, both upward and downward. Sections of the aorta and cardiac substance appeared to be normal when examined microscopically.

Puerperal Convulsions without Albuminuria.—Dr. N. Vuccino gives the case of a lady usually enjoying excellent health, except for occasional hysterical attacks, who in the fourth month of her first pregnancy was seized with a severe frontal hemicrania of quotidian type. At the end of the sixth month she was awakened one night with intense pain in the head, followed by a slight convulsion affecting the upper extremities. In the morning the writer found her suffering from general convulsions, consciousness being lost, and a bloody froth issuing from the mouth; the pulse was small and hard; but the urine was then, and continued to be, perfectly normal. Various methods of treatment having proved fruitless, it was decided to bring on the labor, which was done by injecting hot water (32°). After this had been continued for three hours and a half, the os uteri became fully dilated, and a dead child was shortly afterward expelled. The convulsions ceased as if by magic, and in twelve days she was able to resume her household occupations. She afterward enjoyed good health till the eighth month of her second pregnancy, when convulsions reappeared with greater intensity than before. Chloral and chloroform proving inefficacious, the continual hot vaginal douche was again employed. In consequence of the irregularity of the contractions of the uterus, forceps were required. The convulsions ceased five hours after delivery, and in seventeen days she was again in her normal condition. She subsequently became pregnant for the third time, and during the second month suffered from some premonitory convulsive symptoms, which were increased by vaginal examination; these came to an end on the patient aborting. The author considers the case interesting, as showing how convulsions, due, as he believes, to a highly nervous condition of the uterus, may simulate those connected with renal and urinary mischief. —*The Lancet*, July 18, 1885.

Death from the Sting of a Bee.—The *Medical Press*, July 15, 1885, announces that an ironmonger died recently from the sting of a bee, which attacked him while walking in his garden a fortnight previously. The insect stung the deceased in the neck, and soon afterward the parts swelled considerably and progressively, with the result given. It is rare for such accidents to have a fatal termination, though it is not difficult to conceive such a constitutional state as should render any one so poisoned locally liable to risks affecting even life itself. In this case, probably, inflammation extended along the lymphatic system into what Mr. Bryant very properly terms the dangerous region of the neck, where œdema and possibly suppuration into the cellular tissues around led to interference with the respiratory process.

Latent Pericarditis and Sudden Death.—Drs. Sturgess and Wilkin report a case of fatal pericarditis in which the symptoms were so latent and obscure (*The Lancet*, July 25, 1885) that no suspicion of disease was entertained up to the moment of death. Harry E. B——, a dark, rosy-cheeked boy, aged seven years, and one of a large family, with a perfectly healthy history, had never suffered from rheumatism, scarlatina, or in fact from any illness except chicken-pox, and was accustomed to indulge freely with his brothers in athletic games, no suspicion having ever crossed the minds of his parents that he was not in perfect health. On May 6, 1884, after returning from morning school, he dined heartily at 1 P.M., and immediately afterward commenced to play cricket. This he continued to do until it was time to go to afternoon school, about 2.15 P.M. He then ran with two of his brothers a distance of about a quarter of a mile, and on arriving in the playground he suddenly fell down. The master, who saw him fall, ran to pick him up, and, finding he was insensible, carried him into the house and laid him flat on a table, undoing his collar and bathing his face with cold water, while medical aid was sought. Dr. F. Sturgess arrived about five minutes afterward and found him apparently dead, and, perceiving the many difficulties of the case, sent for Dr. Wilkin, meanwhile performing artificial respiration by Silvester's method. A few minutes later Dr. Wilkin arrived, and after about ten minutes artificial respiration was given up, there being no sign of returning life. The physicians were told that the boy had breathed heavily two or three times after he fell. This fact negatived the momentary surmise of possible complete occlusion of the larynx by some foreign body. Death from the brain must also be excluded in a subject so young. Sudden failure of the heart's action was therefore the only conclusion they could come to under the circumstances. But why the heart should fail in this boy, who looked the picture of health and vigor, they could not explain, and there was no history or reason to suppose he had sustained any blow or shock over the solar plexus. At the autopsy, on opening the abdominal cavity a full stomach was found; the colon was distended with flatus, and the sigmoid flexure was

loaded with fæces; the kidneys and other abdominal organs appeared healthy. On opening the pericardium a fibrous band was found, about an inch broad and the same in length, forming a connecting link between the left apex of the heart and the pericardium, covering the surface of the diaphragm. Numerous other string-like adhesions were seen, particularly on the left side and base of the heart, and there was also some recent lymph, but no serous effusion. These bands were evidently of recent date, as the heart required careful handling to avoid breaking them down. The left ventricle was decidedly hypertrophied, making every allowance for rigor mortis; it was completely empty, as was also the left auricle. The right side of the heart contained some liquid blood, but there was no clot either there or in the pulmonary artery. The valves were all perfect, and there was no endocarditis. The lungs were normal in every way. The cranium was not opened. They were not able to obtain any urine for examination, though there was no reason to suppose it would have given anything but negative results. The immediate cause of death in this case must no doubt be attributed to defective innervation of the heart, which was very greatly embarrassed, not only by the adhesions and impediments within the pericardium, but also by the loaded and distended condition of the abdominal organs, and thus it succumbed under the unfortunate strain it was subjected to.

Bicarbonate of Soda in Tonsillitis.—In the *Australasian Medical Gazette* Dr. Kendall, in referring to this subject, says that he has been in the habit of using the drug for the last four years, and as yet it has never failed to pròduce a good result. The remedy was introduced to the profession by M. Gine, of France. He claimed that by the use of the drug he was able to cut short an attack of tonsillitis twenty-four hours after the application of the powdered salt to the tonsil. Such a rapid cure has, however, never occurred in Dr. Kendall's practice, but he has had very good results in thirty-six hours and forty-eight hours, although in elderly people the attack has lasted five or six days. The drug is, he thinks, well worthy the attention of the profession on account of the absence of baneful properties, and is without doubt useful in cases of inflammatory sore throat due to the influence of cold on an exhausted nervous or muscular system.

Congenital Tuberculosis.—Professor Johne remarks that, though the occurrence of tuberculosis had often been observed, both in the human infant and the calf, so soon after birth as to lead to the conclusion that it was inherited from a parent known to be tuberculous, it had rarely been possible in the human subject to obtain a *post-mortem* demonstration of the presence of the bacilli early enough, or, in either case, to otherwise exclude the possibility of extra-uterine infection by means of the milk. The author having requested a number of his friends to send him any fœtuses of tubercular cows that might come under their notice, received, on February 20th, of this year, from Mr. Misselwitz, a veterinary surgeon at Chemnitz, the lungs and liver of an unborn fœtal calf, in the eighth month of intra-uterine life, whose mother had been slaughtered on account of advanced pulmonary tuberculosis. In answer to his inquiries, Mr. Misselwitz assured Dr. Johne that the uterus and placenta were free from the least trace of tubercle, and that all the fœtal organs, with the exception of the lungs and liver, were quite healthy. Dr. Johne found the lungs of normal size, color, and consistence throughout, except that in the hinder side of the upper lobe of the right lung there was a yellowish-gray well-defined nodule, of the size of a pea, the overlying pulmonary pleura being somewhat clouded; and on section, four more nodules, not larger than millet-seeds, were seen, cheesy, and partly calcified, embedded in a grayish, firm, and apparently homogeneous material. The bronchial glands, larger than hazel-nuts, were mottled superficially, and filled with cheesy, partly calcified yellowish nodules, of the size of small peas. The liver, otherwise normal, was studded throughout with countless miliary tubercles, the smaller gray, the larger cheesy within and partly calcified externally. The condition of the portal glands was the same as that of the bronchial glands, though more advanced. The naked-eye appearances were unmistakable; but the microscopic examination and staining of the various preparations displayed in the most characteristic manner the typical structure of bovine tubercle, as well as the presence of the bacilli in the giant-cells, and most abundantly where the caseated parts were in contact with the outer layers of epithelium-cells. In no part were any spores detected. Dr. Johne believes that this is the first unequivocal case of intra-uterine tuberculosis on record; even Dr. Croker's case, three weeks after birth, having been conceivably one of infection. The more advanced state of the tubercular process in the liver and adjacent glands than in the lungs would naturally follow the entrance of the bacilli with the placental blood by the umbilical vessels. Dr. Johne supposes that they were transported from the maternal to the fœtal circulation through the walls of the placental vessels, by the penetration of the latter by the leucocytes in which they were contained. Soon set free by the breaking down of the leucocytes, they lodged themselves in the lymphatic structures around the portal vessels, setting up multiple tubercles, comparatively few being carried onward to the lungs, and there only at a later period.—*London Medical Record.*

Antidotes for Strychnine.—Lewin states that nitrite of amyl is not a true antidote to strychnine, it only retards the fatal issue, and as soon as its effects pass away the tetanic spasms recur. Faucon and Debierre have recommended the employment of iodine and of tannin. These drugs form, with strychnine, a very slightly soluble substance, so that the action of the poison is suspended for a time. Then an emetic can be administered, and immediately afterward hydrate of chloral. The latter can be given in very large doses. Faucon and Debierre gave, in one case of strychnine poisoning, nearly two ounces of chloral in the course of fifty-nine hours.—*Annales de la Société Médico-Chirurgicale de Liège*, July, 1885.

Resection of the Ankle.—Dr. P. Liebrecht, of Liège, describes an operative procedure which he has recently devised for resection of the tibio-tarsal articulation in cases of fungous arthritis (*The London Medical Record*, July 15, 1885). The methods that have hitherto been practised are all, he states, attended with much labor, in consequence of the difficulty in exposing and dividing the numerous ligaments of the ankle, and are apt to cause injury to the tendons, vessels, and nerves around the joint. The following is a description of the author's method, which, however, has up to the present time been performed only on the cadaver. The skin incision is made from the middle of the posterior border of one malleolus to the middle of that of the opposite malleolus. The tendo Achillis is then divided on a director. A second division, perpendicular to the first, is now made along the inner border of the tendo Achillis. This is about two and one-half inches in length, and, passing downward, almost reaches the inner tuberosity of the calcaneum. The soft structures between the tendon and the bone are now dissected away, so as to expose the capsule of the joint and the posterior peroneo-astragaloid ligament. On excision of these ligaments, the astragalus and the lower extremity of the tibia are exposed to view, and also the line of articulation between these bones, and, below this, the astragalo-calcanean line. The tendon of the flexor longus pollicis is then displaced inward from the posterior surface of the tibia, and all the tendons, vessels, and nerves situated behind the two malleoli can now be easily pushed forward, so as to expose the whole of the posterior aspect of the joint. If the bones be hard, as is mostly the case in the cadaver, the

posterior surface of the astragalus, at one of its borders near a malleolus, should be attacked with chisel and mallet. A notch should first be made along the whole width of the bone, so that by subsequent action of the chisel the upper portion of the astragalus may be removed in one piece. If necessary, one or more slices of bone may be afterward removed. The end of the tibia, if diseased, may be excised in a similar manner. If the diseased bone be very soft, it may be scooped away. The articular surfaces of the malleoli having been exposed, they may be scraped or removed with the chisel. The lateral ligaments may now be divided with a blunt-pointed bistoury. If any fragments of the astragalus remain adhering to the capsule or ligaments, they should be torn away with forceps. A large cavity is thus formed, at the bottom of which is found the articular capsule of the front of the foot, which may be readily scraped, or, if necessary, excised with scissors. If the loss of bone be not very great, and particularly if the malleoli have been partially preserved, the cavity may be left to become filled up by granulations; and then, after recovery, the patient will have a foot that is almost normal. When it has been found necessary to remove much bone, the opposed osseous surfaces of the leg and tarsus should be fixed together, so as to attain osseous ankylosis. Finally, the divided extremities of the tendo Achillis and edges of the external wound should be brought together by sutures. Dr. Liebrecht claims for this operation the following advantages: It does not cause any serious primary lesion, or necessitate any useless sacrifice; the soft parts and the periosteum are not bruised in the course of the operation. It offers more chances than the other methods of preserving a limb of normal form, and better assures the integrity of its functions. It may be easily and quickly performed. Owing to the position of the wound, the discharge of secretion will be effected without any difficulty, and the process of repair will be carried on much more rapidly.

Destruction of the Cochlea without Loss of Hearing.—The loss of the cochlea is usually supposed to be equivalent to a complete loss of the power of hearing, but a case related by Grüber to the Vienna Medical Society would seem to prove that this is not so. A youth, fifteen years of age, came under Professor Grüber's care on account of chronic otorrhœa and polypi in the left ear. He had much pain, and there was paralysis of the left facial nerve. The polypi were removed, and during the operation the necrosed cochlea also came away. Soon afterward the patient's condition began to improve, pain ceased, and the facial paralysis diminished. The left ear not only regained the power of recognizing sounds, but even of distinguishing musical notes. Two similar cases have been reported, one by Cassels, of Glasgow, and the other by Christinneck, of Halle. The labyrinth has hitherto been regarded as a sort of *noli me tangere*, but these cases prove that the entire cochlea may be lost, and still the power of hearing be preserved. —*Gazetta Medica di Roma*, July 15, 1885.

Tricuspid Stenosis.—Professor Torres Homem relates, in the *Revista dos Cursos Praticos e Theoricos do Rio de Janeiro*, vol. i., No. 1, a very rare case of stenosis of the right auriculo-ventricular valve unassociated with insufficiency. The patient was a man, thirty years of age, who had suffered from two attacks of acute articular rheumatism, and was also a hard drinker. He had never had syphilis nor any pulmonary affection. He was obliged to handle heavy sacks of coffee, and on one occasion, after severe muscular effort, he noticed a slight œdema of the lower extremities. This continued to increase until, at the time of admission to the hospital, there was excessive general anasarca of the entire body. Dyspnœa was not very pronounced, and there was no severe cough. A few subcrepitant râles could be heard at the base of both lungs. The urine was free from albumen. The pulse was small but regular. The jugular veins were large, and undulatory movements were noted in them, but there was no true venous pulse. There was a very pronounced increase of the precordial area. On auscultation a short and plainly diastolic murmur was heard during the first two days of the patient's stay in the hospital. But on the third and subsequent days, up to the time of his death, the murmur was presystolic, being heard just at the end of the period of rest, and immediately before the commencement of the ventricular systole. Its seat of maximum intensity was just at the union of the sternum with the ensiform cartilage, and was propagated along the right of the sternal border and slightly also to the left. Nothing else abnormal could be heard in any part of the heart. At the autopsy there was found to be a fibro-cartilaginous ring encircling the base of the tricuspid valve, narrowing it so as hardly to admit the extremity of the little finger, but there was no insufficiency. The other valves were normal. The lungs were œdematous. This case is very interesting as a pathological curiosity, for uncomplicated stenosis of the tricuspid is such a very rare lesion that both Peter and Constantin Paul have denied its existence, and other writers have expressed doubts as to its possible occurrence.

Treatment of the Hysterical Attack.—Dr. Albert Ruault relates, in *La France Médicale* of July 25, 1885, a simple method which he has found very efficacious in controlling an hysterical fit. It consists in making firm and constant pressure over the supraorbital nerve at its point of emergence from the supraorbital foramen. The head is held securely between the palms of the hands, while pressure is made over the nerve on each side with the thumbs. The writer says that the patients under this treatment first contract the facial muscles with an expression of pain, cry out, and then take several quick successive inspirations. The breath is held for a few seconds, and then, with a long expiration, the muscles relax, and the attack is ended. The pressure of the thumb should now be relaxed, otherwise it may have the opposite effect and excite another convulsion. Pressure over any nerve-trunk at the point where it becomes superficial will have the same effect; but the supraorbital nerves are chosen because of their convenient situation.

The Differential Diagnosis between Indurated Chancre and Herpes.—It sometimes happens that herpes of the penis presents itself under the form of a single patch of superficial ulceration, accompanied by some induration of the underlying tissues; there may be also a swelling of the inguinal glands, so that the diagnosis between this so-called chancriform herpes and some forms of indurated chancre is very difficult in the early stages. Dr. Leloir, however, calls attention to the fact that when a herpetic ulcer is pressed between the fingers a drop of serous fluid is squeezed out (*The British Medical Journal*). This manipulation can be repeated several times with the same effect; in the case of chancre, on the contrary, a little fluid is seen on the surface, but the quantity is not increased by pressure. When the base of the herpetic ulcer is indurated, the hardened tissues can be flattened between the fingers, while, in chancre, no amount of pressure can change the shape of the nodule. This difference is explained by the fact that in herpes there is a localized œdema of the tissues, while in chancre the chief lesion is a hard infiltration, sometimes accompanied by sclerosis of the connective tissue and of the vessels.

Bedside Testing for Albuminuria.—Mr. G. P. Best describes, in the *British Medical Journal*, an ingenious plan for testing urine. He dips a syringe into the chamber-utensil and draws up a small quantity of the urine, and then, inserting the nozzle of the syringe into nitric acid, sucks in a drop or two of that fluid; the well-known hazy line at the touching point of these two fluids indicates the presence of albumen.

Poisoning by Extract of Conium.—*The Lancet*, July 25, 1885, gives the following account of a case of poisoning by conium. It concerned an infant, aged eight months, who, with the exception of irritability from teething, was in good health at the time the fatal dose was given. To allay the fretfulness, a physician ordered a mixture containing one drachm of extract of conium, one drachm of bromide of potassium, and an ounce and a half of chloroform water, one tablespoonful to be given every four hours until sleep was induced. The prescription was taken to a chemist's, who, recognizing the unusual dose for so young a patient, contented himself with cautioning the father against giving too much of the mixture, remarking at the time that "no doubt the doctor meant a *tea*spoonful, and not a *table*spoonful." Accordingly, a drachm of the mixture was given at eight o'clock P.M. The effect soon became manifest, and by half-past eleven the symptoms were so alarming that another physician was hastily summoned. On his arrival he found the lower extremities completely paralzyed, occasional twitchings of the arms and head, but no decided convulsion, marked dilatation of the pupils, lividity of the face, and diaphragmatic breathing. At that period he appears to have recognized the hopelessness of the case. Mustard poultices were applied, and attempts made to induce vomiting, but without effect. Death occurred at three A.M., on the following day, seven hours after the medicine was taken. There was no vomiting. At the inquest, the physician first in attendance admitted that he had made two mistakes in the prescription: first, in writing a tablespoonful instead of a teaspoonful for a dose; and, secondly, in ordering the extract of conium instead of the succus. He could in no way account for this. In his opinion death was due to asphyxia from idiopathic convulsions, and not from the action of the drug. He quoted from the writings of Harley and Farquharson to show that the *extract* is comparatively inert and totally unreliable. Mr. Pepper, who conducted the post-mortem examination, and analyzed the mixture and contents of the stomach, deposed that the body was well-nourished and showed no traces of organic disease. The organs generally were much congested. The brain presented marked increase of serous fluid in the ventricles and beneath the arachnoid. The membranes of the spinal cord were strongly injected. The right side of the heart was distended with semi-coagulated blood. The bases of the lungs were gorged with blood, and the surface marbled with patches of congestion, collapse, and acute emphysema. The surface of the liver presented numerous groups of punctate extravasations. The bladder was empty. The alimentary canal was free from all signs of irritation. In the stomach were about eight ounces of thick, grayish-yellow, pultaceous matter, consisting, apparently, in chief part of altered milk. There was no noticeable odor beyond the ordinary sour smell of gastric contents. On adding some liquor potassæ, and boiling, however, a strong smell like that of mice was developed. An ethereal extract yielded on evaporation green oily drops, consisting of vegetable coloring matter and the alkaloid conia. The latter gave, with hydrochloric acid, an abundance of acicular and stellate crystals. Several other tests furnished affirmative results. Mr. Pepper, whilst admitting that the extract of conium was of uncertain composition, and therefore untrustworthy in its administration, and, further, that a much larger quantity than the officinal dose was required to produce the characteristic effects, could but conclude from the evidence tendered by Mr. Freeman, the physician last in attendance, that the actual cause of death was asphyxia from paralysis of the respiratory muscles. The maximum dose for a child eight months old would be about one-twelfth that for an adult; consequently the deceased took ten times the full quantity ordered by the Pharmacopœia. The fact that the stomach contained a considerable quantity of food explains the somewhat protracted course of the symptoms, whilst the absence of vomiting conduced to the fatal issue. *The Lancet* believes that the above is the first recorded case in which death has ensued in the human subject from an overdose of any of the authorized preparations of conium.

Respiratory Croaking of Babies.—Dr. Samuel Gee has seen about a dozen cases of what he calls respiratory croaking in babies ("Saint Bartholmew's Hospital Reports," vol. xx., 1884). Breathing is accompanied by a croaking noise, which seemed to Dr. Gee to have the characters of stertor more than of stridor; or, in other words, the sound seemed to be produced in the fauces and not in the larynx. The croaking usually accompanies inspiration only, but in one of the cases it accompanied expiration only. The noise is constant, both when the child is awake and when she is asleep; yet it may cease for a short time now and then. The tone of the cry is natural, and this is another reason for believing the noise not to be laryngeal. No dyspnœa, no recession of chest-wall during inspiration. Fauces look natural. The noise continues when the nose is pinched. The croaking has nothing whatever to do with the crowing of laryngismus stridulus; the two disorders resemble each other in no respect, except that there is a noise produced in each. The ages of Dr. Gee's patients ranged from three to nine months. It is a remarkable fact that all of them were girls. The general health of some of the children was good, but most of them were weak and sickly. Two children suffered from congenital disease of the heart, and one was an idiot. In some of the children this croaking began at or soon after birth, and in no case did it last much beyond the end of the first year. There is no special treatment; indeed the disorder causes more annoyance to others than to the child herself.—*The Boston Medical and Surgical Journal*, August 13, 1885.

Changes in the Eye in Cholera.—Even in the early stages of cholera there is cyanosis of the eyelids, and when this condition becomes general it is always more marked in the lids. Difficulty is experienced in closing the eyes, and there is almost always a space between the upper and lower lids, leaving exposed a portion of the sclerotic. The lachrymal secretion is greatly diminished, so that even in the agony caused by the cramps no tears are seen to flow. In all grave cases in which palpebral occlusion is difficult there is an injection of the lower portion of the conjunctiva corresponding exactly to that portion which is left uncovered by the lids. In the stage of reaction there is sometimes seen a general hyperæmia of the conjunctiva, due to the presence of an actual catarrhal inflammation. Dr. Joseph has occasionally observed ecchymoses in the inferior portion of the conjunctiva, which he has learned to regard as foreshadowing a fatal issue. In some very severe cases, toward the end of the algid stage, a lesion is seen in the lower portion of the cornea, which may be regarded as a partial necrosis. There is a loss of substance in the cornea, producing a small round ulcer of a gray opacity, which may increase later. Graefe regards this as a neuro-paralytic keratitis. Of fatal prognostic import are the black or dark-bluish spots in the sclerotic along the inferior border of the cornea. They are of irregular shape and may be discrete or confluent. These are independent of the ecchymoses in the conjunctiva and may appear suddenly without any previous conjunctival affection, and even in parts covered by the lids. In the algid stage, according to Graefe, the pupils are moderately contracted, a phenomenon which he attributes to paresis of the sympathetic. Finally, the alterations observed in the retinal circulation consist in an extreme contraction of the arteries. The veins are indistinct, but unchanged in their calibre. There is, however, never complete ischæmia of the retina, and it is uncertain whether the transitory blindness, occurring at the commencement of the algid stage, can be explained by the changes in the retinal circulation.—*La Crònica Médica*, July 20, 1885.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, September 12, 1885.

ENDOWMENTS FOR MEDICAL INSTITUTIONS.

IN an article published in the September number of the *Popular Science Monthly*, under the title "The Present Aspect of Medical Education," Dr. William Gilman Thompson makes an earnest plea for the endowment of medical institutions, and he gives us some interesting statistics on the topic, abstracted from various educational reports of recent date. The history is traced of the emancipation of exact medical science from the superstitions of mediæval times, and there is shown the wonderful revulsion of public opinion which has occurred in regard to some of the aspects of practical medical work. One hundred years ago it was impossible, the writer tells us, to obtain bodies for dissection except by stealth, and even now, in some of our Western States, occasional outbreaks of body-snatching occur. Contrast with such a state of affairs our present well regulated law in New York, where, under full legal protection, an abundant supply of material is easily obtained.

From the article in question we learn that the endowments of our medical institutions are comparatively small. Eighty-seven "regular" colleges report funds amounting to $350,000, with an annual income of $20,000; sums most meagre in comparison with the endowments of our classical institutions, and relative to the importance of medical work. There is, however, we think, a well-defined reason for this difference. Most of the endowments of our great colleges have come from graduates thereof, whose generosity has been the outgrowth of a sort of feeling of personal affection for their Alma Mater. This personal feeling springs from several different sources. The strong social element in the undergraduate life of our academic institutions, and the formation of lifelong friendships, contribute more perhaps to the establishment of this Alma-Mater feeling than does the sense of benefits received. This may argue a very low estimate of educational advantages, but we believe that these facts are essentially true. Now, in the course of medical instruction as it is at present, and doubtless always will be, carried on, there is no soil in which such a feeling may take root. There is no social side to the college life in the academic sense. The personal relation between instructors and instructed are more distant. Hence the powerful incentive to giving before mentioned is absent.

It is true that, on purely ethical grounds, it is for the advantage of the wealthy classes in any community to equip its medical institutions as thoroughly as possible. Much more, even for their personal interest, should such be the case; but the average man of means regards his own responsibility in this direction as so remote that it soon ceases to be any responsibility at all.

Dr. Thompson decries the establishment of so many small medical colleges, particularly in the West. No less than fifty-one have been started and given up during the last century. Some of these, in former decades, did good work. They filled a then existing want. Having accomplished their purpose they vanished. The expansion of the country brought about a new educational environment, so to speak. Under this change of conditions the old principle of the survival of the fittest operated with its usual result. Let us not underestimate the value of some of these earlier institutions. They turned out well-balanced men who could and did successfully grapple with the problems of their times; who better estimated, perhaps, the physiological factor of disease than some of us whose attention seems wholly bent on its physical aspects.

We think that before the community becomes fully alive to the necessity of endowing medical institutions, the faculties thereof must initiate the spirit of self-sacrifice. Many of our medical colleges are essentially chartered companies, the faculties being the stockholders who draw their dividends out of the students' fees. Too often, the principle of competition, a veritable "cutting of rates," comes in to hinder any advancement toward a higher plane of scholarship: the more students, the more fees and larger dividends. The low standard of graduation is only too painfully apparent. Students are allowed to enter at too early an age and with insufficient preparations. True reform in all these directions means, for some years at least, a diminution in the number of students. For contracting this lessening of receipts, and for conducting the institution properly, must the endowment fund suffice.

We do not think it entirely erroneous that a medical college can flourish apart from a large city. There are several institutions in the country, apart from those in the cities, which have always been noted for the excellence and thoroughness of their theoretical instruction. Their graduates generally supplement this by a season's residence at some large medical centre, where they well attest the superiority of their previous training.

We regard the signs of the times as most cheering, in regard both to the ultimate raising of the standard of graduation, and to the realization by the community of its own individual relation to the medical college. The history of endowments well illustrates the Scripture truth, that "to him that hath shall be given." May we not hope that the tide of benevolence will soon more strongly set in to placing our well-matured institutions on a solid, independent financial basis?

RESULTS OF INVESTIGATIONS REGARDING SOME NEW DRUGS.

THE Connecticut State Medical Society has undertaken a work of collective investigation which is likely to lead to results of some practical value. A committee appointed by the said Society has issued circulars of in-

quiry on the subject of certain new drugs which have lately been put on the market with more or less strong endorsements. The answers so far obtained relate to convallaria maialis, piscidia erythrina, cascara sagrada, and certain of the oleates.

The conclusions reached are by no means positive, but are at least valuable and suggestive.

With regard to convallaria maialis, fifty replies were received. The testimony was to the effect that convallaria does not have any cumulative effect, that it rarely disturbs the stomach. It appears to be milder and less certain in its action than digitalis. It is doubtful whether it has much diuretic effect.

Piscidia erythrina, or Jamaica dogwood, has been announced as a drug having hypnotic and anodyne effects. The thirty-two answers received by the committee show it to be very doubtful whether any such properties exist to a sufficient extent to warrant its introduction into medicine. The specific effects are sometimes obtained, but not with any certainty. On the other hand, it is possible that too small doses were given on account of a supposed danger in its use.

Cascara sagrada is a remedy that has been widely used and well spoken of. Its effects are those of a stomachic tonic and laxative. The forty-seven replies obtained by the committee hardly sustain the view that this drug is a superior one for use in habitual constipation. Many find that it is useful, but few think it in any wise specific. A majority did not find its effects diminished by constant use. Dr. Thomas H. Russell, who made a number of careful observations speaks most highly in its praise. He advises its use in doses of from fifteen to thirty drops of the fluid extract three times a day. On the whole, it is safe to affirm of cascara sagrada that it is one of the best medicines for habitual constipation.

The contributions to the subject of the oleates are sufficient to justify any conclusions as to the special superiority of these preparations.

The Connecticut Medical Society has entered upon a useful line of work, and we trust it will continue its investigations. Well-organized medical societies can by means of collective investigations in certain lines do as much as the city professor with his hospital wards. There needs to be only a careful selection of subjects, and, so far as possible, some personal knowledge of the character of the workers. Some men have no power of weighing evidence and reaching sound conclusions. It is this fact that limits the usefulness of collective work, and makes it necessary for those conducting it to be extremely careful.

CORPORATE MEDICAL TREATMENT.

In a thoughtful address delivered by Mr. Rawle, a prominent Philadelphia lawyer, before the Phi Beta Kappa Society at Harvard, attention was called to the fact that in the law a great deal of the work formerly thrown in the hands of young lawyers is now done by corporations. The fact was used to illustrate the greater difficulties now encountered by educated young men in gaining a foothold in a profession.

Medicine, to a greater extent than the law, has of late broadened its opportunities and extended its work. Despite sanitary science there seem to be just as many ill, and perhaps there is much more of introspective invalidism and trivial doctoring. But, like the law, medicine is tending to do more and more of its work through corporations; and the young doctor, as well as the young lawyer, soon runs afoul of these. In great cities nearly one-fourth of the population is treated annually through the beneficence of incorporated dispensaries. Hospitals for every class of diseases are being built, and there is an increasing tendency for those even who are well-to-do to go to such institutions when taken ill.

It is not, however, these institutions, but a new phase of corporate medical development to which we wish to call attention. A correspondent has sent us a number of documents setting forth the existence, purposes, and mode of procedure of a certain quack "Remedial Agency" that is flourishing in this city. It consists of a "medical consulting board of seven members," a business manager, a corps of stenographers, etc. The medical men include one or two who have formerly been known in the ranks of the regular profession. This interesting corporation advertises itself liberally, appealing, it appears, mainly to the sexually distressed. Upon application for treatment being made by a patient, an answer is promptly given inclosing a blank form for the patient, to be filled out, asking for a sample of urine, and assuring the inquirer that a cure can be made "after a course of treatment." The data being obtained, another letter and a variety of medicines and appliances is forwarded along with a circular form containing explicit directions as to treatment.

This latter is a highly interesting document. "You will," it says, "by direction of the Medical Director use the remedies as follows:

"No. 1 course every night, No. 2 course, every morning. Pre-marital course, every morning and night. The cradle-compressor to be worn during the day." An "abdominal electro-girth" is to be worm *pro re nata*, a "tissue is to be applied to the glans penis night and morning," a magnetized voltaic pile, a "developmental lotion," and certain blood and liver pellets are among the resources of this interesting establishment. The patients are sagely advised to bathe at least twice a week, and dumb-bells are recommended as advantageous.

Accompanying this document is an itemized bill, by which we learn that the cradle-compressor costs $6, the pills $14, and the "courses" respectively, $20, and $15, making a total of $55. This seems certainly more profitable than selling patent medicines at a dollar a bottle.

It is needless to say that such institutions as the above are an injury to the public and not a whit better morally than the "sawdust-swindlers."

If they are found to be increasing, it will be the duty of those concerned in public welfare to expose and denounce them.

THE INTERNATIONAL CONGRESS.

The Committee on Organization of the International Medical Congress held its special meeting in this city last week. The meetings were held in secret, and secretiveness seemed to have been the essential feature of the proceedings. Doubtless the gentlemen thought they were

acting very wisely; but they need hardly have taken so much trouble. When members, supposed to represent the interests of the profession, meet at a critical time, with mystic rites, refusing all information except to members of their own clique, they at once simply overreach themselves.

There is but one inference as to last week's work. The Committee has done a foolish thing, and it prefers to cloak its folly until it can be set forth as wisdom in the gilded rhetoric of the chosen organ.

The Committee, we have every reason to believe, made no concessions which can be accepted as such. They filled the one hundred and twenty odd vacancies with gentlemen sufficiently unknown to fame to have escaped nomination by them before, and presumably sufficiently poor in spirit to accept belated honors.

THE NEW DIVISIONS OF APHASIA.

Probably most of our readers were taught and still remember that aphasia is divided into two types—the amnesic, in which there is loss of memory of words; and the ataxic, in which there is loss of power of co-ordinating the articular movements. The significance of aphasia, its pathological anatomy, and the two divisions of it above referred to, were first made out by Bouilland, Trousseau, and Broca. For many years the teachings of these men and their pupils were accepted, and became part of medical pathology. The French school appeared to revere the utterances of their older leaders too much to investigate further. It fell to the Germans, therefore, to find new phases of this peculiar disorder. Marcé, Kussmaul, and Wernicke, called attention to the fact that in some cases patients could speak or write perfectly well but could not understand spoken, or, perhaps, written words. There were, in other words, defects in the receptive part of the language faculty. They called these defects sensory aphasia, and divided this into the two forms of "psychical deafness" or "psychical blindness" according as the patient was unable to understand spoken or unable to read written language.

The French school at first viewed with doubt and distrust these contributions to a subject which seemed to belong especially to themselves. Some four or five years ago, however, Charcot met a typical case of sensory aphasia in his wards at La Salpêtrière. He at once began to study the subject with his accustomed energy and penetration. His labors, together with those of his pupils, have added greatly to our knowledge of aphasia, and Gallic prestige has been quite restored. If the French observers have not yet mastered the subject, they have at least got sufficient data to formulate a clear and definite doctrine of aphasia. According to this school, aphasia is to be divided into two grand types: the motor and the sensory, or as Charcot prefers to call them, aphasia of transmission and aphasia of reception.

Motor aphasia is of two kinds, aphemia or loss of the memory of the co-ordinated movements necessary to speech, and agraphia or loss of the co-ordinated movements of writing. Aphemia is caused by a lesion of the foot of the third left frontal convolution. The lesion in agraphia is very probably at the foot of the second left frontal convolution.

The sensory aphasias are similarly divided into psychical- or word-blindness, and psychical- or word-deafness.

The patient in the first instance can talk and understand what is said to him, but cannot understand or read written language. It is all Greek to him, though it may be his native tongue. He sees the signs, but cannot interpret them. The lesion here is in the left inferior parietal lobule, and the aphasia is accompanied by hemianopsia.

In psychical deafness the patient can talk and read, but does not understand spoken language. The lesion here is in the first left temporo-sphenoidal convolution.

The sensory aphasias, more especially psychical deafness, corresponds measurably with the older amnesic aphasia, while aphemia corresponds to some extent with ataxic aphasia. It is just as well, however, to drop for the present the terms amnesic and ataxic, and use the newer terms, motor and sensory.

It will be seen that a careful study of speech disorders may reveal a good deal with regard to the seat of the lesion. First of all, if there is aphasia, the lesion in a right-handed man is on the left side. Then, according as the particular form predominates, the seat of the disease may be inferred.

It must not be supposed, however, that all cases of aphasia can be sharply classified and assigned to one type or the other. Very often the symptoms are mixed, or change with the progress of the disease.

Again, the classification which we have given is by no means complete or final. A careful study of cases and of the mechanism of language enables the enthusiastic scientist to multiply the forms of aphasia almost indefinitely, so that Lichtheim, for example, gives us seven or more varieties.

These subdivisions, however, have only a theoretical interest.

The classification and forms which we have given, should be known, because a knowledge of them will be helpful in diagnosis.

Ohio Physicians and the International Medical Congress.—The President of the Ohio State Medical Society, Dr. William Morrow Beach, called a meeting of the physicians of the State "to take counsel respecting the situation, and offer suggestions or give instructions to the State representative." In response to the call some twenty or more physicians met in secret session at Columbus, on August 27th. What these gentlemen decided to advise their representative we do not know, nor does it matter, since neither technically nor morally had they the slightest right to instruct their State representative on the Executive Committee.

The New York Polyclinic.—The Winter Session of the New York Polyclinic for 1885–86 opens on Monday, September 21st next. For the year which closes on that date, 235 physicians have attended the clinics of this school, making a total attendance for the first three years of the Polyclinic of 578. No changes will be made in the methods of teaching which have made this institution so attractive to practitioners.

News of the Week.

THE CONTROVERSY ABOUT CODES, AND THE INTERNATIONAL MEDICAL CONGRESS.—Dr. H. D. Noyes, of this city, has kindly sent us the following letter to Professor Hansen-Grut, of Copenhagen, and the reply thereto by that gentleman:

"The enclosed letter came a few days ago in reply to certain questions which I had asked. Professor Hansen-Grut was president of the Section of Ophthalmology in the Congress at Copenhagen, he resides and has a clinic in that city; he is a well-known man. He took an active part in the preparations for the Congress, in its conduct, and in getting out the Transactions. His statements as to the rules which governed its composition are authoritative.

"He is perfectly familiar with all that was said and done, and intended and understood, when the invitation to hold the next Congress in Washington was accepted. The views he expresses are those which were in the minds of the European members, and especially in the minds of the responsible executive officers of the Copenhagen Congress, when the next place of meeting was decided upon.

"I put the question to him in my letter of inquiry, about the admissibility of homœopathists, to more than cover the ground of dispute among us about the Code of Ethics. His statements completely put all those questions at rest, and demonstrate that there is absolutely no reason for any ethical distinctions, and moreover, that no body of men or any organizing committee have the right to impose any such qualifications upon members, nor in the choice of officers. With this letter, this element of discord in the organization of the Congress of 1887 should go out of existence.

"Professor Hansen-Grut was in this country in 1876, as a member of the International Ophthalmological Congress in New York. His remark about not expecting to find such exclusiveness in our country, is a most natural expression which will rise to the lips of every intelligent foreigner, and conveys to us an unintended rebuke which may well make us wince. The italics in the letter are by the author. Professor Lange, of whom he speaks, was Secretary General."

"HUMMELLAFT, DENMARK, August 21, 1885.

MY DEAR DR. NOYES:

"I am sorry you have so much bother about the Congress. The spirit that is at the bottom of the dispute is to me a proof of such exclusiveness as I would not have expected to find in your country.

"I will answer to question

"(1) That the controversy about Codes was never thought of, as we have nothing resembling your Codes of Ethics.

"(2) The invitation was decidedly given for the *whole* medical profession, none of us thought of or even mentioned the American Medical Association.

"(3) The *only* qualification required was that the member be a *legally acknowledged* medical practitioner in his country. *Our* homœopathists, who were legally acknowledged practitioners (Drs. Siemsen, Ferich, and others), were actually members, and undisputed members of our Congress.

"I have sent your letter to Professor Lange, who will no doubt corroborate my statements. To my knowledge he has already had similar questions addressed to him from America, and answered them in the same way as I have now done.

"The way across is long, the fear of the sea is strong. I do therefore firmly believe that it is injurious to the interests of the Congress to have too many restrictions put for admittance. Yours sincerely,

"EDWARD HANSEN-GRUT."

THE CHOLERA IN SPAIN, FRANCE, AND ITALY.—Up to August 28th the total number of deaths from cholera in Spain had reached 81,489. The number of cases at date of writing is over a quarter of a million. In those provinces of Spain which were first affected, the plague is diminishing, but in other parts of the country it is still spreading. On September 1st the number of cases reported was 3,669, with 1,120 deaths. This shows a diminution in the mortality-rate, which has a favorable significance. The returns for the whole of Spain show that there has been, during the past week, a slight diminution in the number of cases and in the mortality-rate. Cholera has appeared at several different places in Italy during the past week, viz., in the provinces of Alessandra and Genoa. Between twenty and forty new cases of cholera occur daily at Toulon and at Marseilles. The number does not seem to be on the increase. With such an immense hold as the cholera has got upon Europe, it seems almost impossible that it should not reach this country before its epidemic career is ended.

SUICIDE OF A PHYSICIAN.—A young Doctor, named Curry, living at Red Bank, N. J., committed suicide on September 1st, by shooting himself. The immediate cause was a love affair. Dr. Curry graduated in medicine at Philadelphia.

THE PHILADELPHIA VETERINARY SCHOOL AND HOSPITAL.—The new buildings of the Veterinary Department of the Pennsylvania University were opened on September 1st. It stands on a large tract of land given by the City Council to the new department. It has a frontage of over two hundred and fifty feet, and is built of stone and brick. There is stabling for forty horses, and accommodations for other animals. The "crazy" stall is circular and padded for delirious horses. The students' quarters include a commodious amphitheatre and museum, anatomical room, sixty-six by twenty feet, lighted both sides; histological laboratory, forty by twenty feet; pharmaceutical laboratory, and four private laboratories.

THE UNITED STATES HAY FEVER ASSOCIATION held its annual meeting at Bethlehem, N. H., beginning September 1st.

BIBLIOGRAPHY FOR "PHYSIOLOGISCHE OPTIK."—Dr. Arthur Koenig, of No. 16 Neue Wilhelm Strasse, Berlin, who is editing the bibliographical department of this work, asks for such notices from his colleagues as may assist him in presenting an exhaustive statement.

DRUGGISTS IN CONVENTION.—During the past week the National Retail Druggists' Association, the Pennsylvania State Board of Pharmacy, and the American Pharmaceutical Association held their annual meetings at Pittsburgh, Pa.

The Medical Society of Virginia.—The Sixteenth Annual Session of the Medical Society of Virginia will be held at Alleghany Springs, Montgomery County, Va., commencing Tuesday night, September 15, 1885.

Microscopic Relics of General Grant.—Dr. George R. Elliott, the microscopical expert in General Grant's case, has had the specimens upon which the diagnosis of "epithelial cancer" was based, carefully prepared for permanent keeping in his office. There are eighteen of these slides, which are placed in a mahogany cabinet, upon which are two silver plates, engraved as follows: "General U. S. Grant cabinet of microscopical slides, reported upon as epithelioma, February 20, 1885, by Dr. George R. Elliott. Consulting staff: Dr. Fordyce Barker, Dr. J. H. Douglas, Dr. Henry B. Sands, Dr. Geo. F. Shrady. This cabinet is placed in a larger one made of cocobolo wood, upon which stands a bronze bust of the General.

The Small-pox in Canada.—The epidemic of small-pox in Montreal has finally become a serious matter. On September 7th the Provincial Board of Health held its first meeting to take action in the matter. A public meeting of citizens was also held on the same evening, when resolutions were passed calling upon the authorities to erect a new small-pox hospital at once. Dr. Covernton, of the Ontario Provincial Board of Health, submitted a proclamation, issued by the Ontario Government, prohibiting rags, dry goods, and other merchandise from entering that Province, unless accompanied by a certificate to the effect that they are free from contagion. Four medical men have also been appointed to travel between Montreal and the borders of the Province to examine passengers, and if they have not certificates of vaccination, to vaccinate them at once, if thought necessary, or within fifteen days. These officers have also power to question passengers minutely as to districts from which they come, and if not satisfied with the replies can send them back to the place they came from.

Will the Congress Meet in America?—It would be idle to attempt concealment of the fact that not only is the success of the proposed meeting of the International Medical Congress at Washington imperilled by existing dissensions in the profession of America, but that it is a serious question whether the gathering can be permitted to be held there at all. We are alive to the possibility that the curious arrangements entered into by the clique of the American Medical Association may be fully carried out; but at the same time we are perfectly certain that a congress convened under such circumstances will not be international in any sense of the word, but will develop into nothing more imposing than a magnified mutual admiration society. There is no longer any doubt that all the leading members of the profession in America will at such a gathering be conspicuous by absence, or that European practitioners will fail to find any recompense for this fact in receiving attentions from gentlemen whose names they are unable to associate with the extension or perfection of scientific knowledge or the advancement of the art of medicine. . . . The whole history of the International Congress has nothing so unfortunate as this episode to show, and we are deeply grieved that a great country like America, a country that is closely united to us by the holiest ties of blood and community of thought, should be the first to stir the deep waters of science by the introduction of a miserable and unworthy quarrel about—*ethics*, forsooth! In truth it is a mean and miserable bone that is the cause of contention. What is it to the sacred light of science whether its followers are members of this, that, or the other Association? and who outside the arena of local politics will care a straw for the ethical opinions of men with whom he is associated in common pursuit of a great and honorable profession? We want to meet the doctors of all nations at an international congress; and so that they be doctors and honest men, what other right or title to be present need they have? Possibly, nay, even probably, such catholic invitations as the Congress naturally extends may give admission to a few whose claims to be regarded as doctors *and* honest might be open to criticism —*Medical Press and Circular*.

Dr. Ferrán in Spain.—The cholera continues slowly to abate. It has already attacked about 200,000 persons, of whom about one-third have died. Dr. Ferrán continues to inoculate at $3 a syringeful. Those who can prove themselves poor he inoculates gratis. He urges the necessity of a second "massive" inoculation on the tenth day. Total, $6.

The American Academy of Medicine.—The next meeting of the Academy will be held at New York, on October 28th and 29th.

Dr. P. O. Hooper, of Little Rock, Ark., a general practitioner of long experience, has been appointed to succeed Dr. C. C. Forbes as Superintendent of the State Insane Asylum, of Arkansas.

Preventive Inoculation of Yellow Fever.—In a letter of Dr. Freire, of Rio de Janeiro, to Dr. Ramirez, published in *La Crónica Médica*, of Lima, the writer states that he has vaccinated over three hundred individuals with gelatine cultures of the yellow-fever microbe. The inoculations are made by means of five or six punctures in the arm. As a general rule, a few hours after the operation the subjects experience a slight headache, with bruised feelings in the extremities and lumbar region, and rachialgia. There is an elevation of temperature of 1° or 2° F., and in rare cases there was nausea or vomiting. These symptoms continue for two or three days, but never become dangerous in their severity. The inoculations were practised upon persons living in the very heart of the infected districts, and not one of the subjects died, and only very few suffered from a mild form of the disease, although of their non-vaccinated neighbors two hundred died within a period of three months.

The Congress of the French Association for the Advancement of Science held its annual session at Grenoble, beginning August 12th. M. Verneuil presided, and pronounced a discourse upon "The Surgery of 1885." It was a keen and witty criticism on the prevalent mania for operating—the *prurigo secandi*. In the seventeenth century there was a rage for transfusion; in the eighteenth, every man who fell on his head was trepanned; later, during the wars, every injured limb

was amputated. When Verneuil began his career tenotomy was all the rage; a little later there was a *réséco* mania; now, when one specialist operates, all operate. A prevalent mania at present in France is the application of the cautery. The world, says Verneuil, has been too much transfused, too much trepanned, too much tenotomized, resected, amputated, and far too much *travaillé dans le petit vassin de la femme*. In the medical section, presided over by M. Henrot, M. Landowsky reported cases of epithelioma cured (?) by applications of the juice of *Euphorphia leterodexa*. M. Chauveau made a report upon preventive inoculations for cholera, in which he claimed that the possibility of the efficacy of such inoculations could not be negatived on scientific grounds. M. Lepine read a paper on nephritis. M. A. Voisin reported success in the treatment of mania by hypnotism. M. Paul recommended warm sublimate injections in the treatment of gonorrhœa.

Cholera and the Importation of Rags.—A report from the United States Minister at The Hague states "that in view of the existence of cholera in Spain, the Government of the Netherlands has prohibited the importation of rags, old clothing, linen, and unwashed bedding after June 24th. The law applies also to the transportation of such goods through the country, but does not apply to the baggage of travellers." A very great diversity of opinion exists among sanitary authorities relative to the danger to be apprehended from the importation of rags from cholera-infected ports. A paper was read at the Sanitary Congress in Holland last year, wherein the author claimed that there were instances on record where epidemics of cholera could be traced to the introduction of rags. Many other authorities, on the contrary, deny the persistence of the contagion of cholera for any considerable period in rags, and insist that they should be admitted without restriction. All agree, however, that precautions are necessary to prevent the spread of cholera, and there is a widespread feeling among the people in all countries that the indescribable filth often found in old rags which are from time to time received in all countries from cholera-infected districts are liable to be the bearers of the disease. The English authorities, many of them, are either very skeptical on the subject or openly opposed to taking any action in this matter, though in response to the prevailing feeling, the importation of rags, etc., into England from Spanish ports, except on certain conditions, was interdicted for several months. In April last, however, the embargo was raised, and the whole matter relegated to the local authorities at the several ports. It is worthy of note that the English representatives appointed on the committee on disinfection and disinfectants, by the Cholera Congress recently held in Rome, all of whom have become experts in the treatment of cholera during a residence in India, are said to have abandoned the theory of the infectious or contagious character of the disease, except as it is wafted from place to place in the air. In our own country the action of the Treasury Department in dealing with the subject has been uncertain and vacillating. At one time an order is issued prohibiting absolutely the importation of rags from infected or suspected ports; then the order is modified so as to admit rags that have been disinfected in one of three or four ways; and finally all orders are revoked, and, following the example of the British health authorities, the control of the introduction of rags is turned over to local health officers. The feeble and vacillating course of our Government is in strange contrast with the decisive policy of foreign nationalities. This is the more remarkable in view of the fact that we have a National Board of Health capable of advising the Treasury Department as to the questions relating to the public health involved in the importation of rags. As far as we can learn, that Board has never been consulted previously to the issue of any of these various and often contradictory orders. In any event, the action of the Government in the matter of the importation of rags has been unworthy of an enlightened country, whose commerce extends to the remotest parts of the globe. It was to enable it to adopt a wise policy on all questions affecting the public health of the United States that Congress organized the National Board of Health. But the purpose of Congress has been largely thwarted by officials connected with the Treasury, who aspire to usurp the functions of the Board, and to expend the public funds properly belonging to that body. It is for this reason that our Government now occupies a position inferior to that of any European government in all its acts designed to protect and promote the public health. Its policy is dictated by those who are not only ignorant of the principles of public hygiene, but whose motives are transparently selfish.

Canada Medical Association.—The Eighteenth Annual Meeting of this Association was held at Chatham, Ontario, on Wednesday and Thursday, September 2 and 3, 1885. Hon. Michael Sullivan, M.D., the President, occupied the chair. The attendance was large and thoroughly representative in character. A goodly number of American physicians were present, and were heartily welcomed to all the privileges of the meeting.

The President, in retiring from the chair, congratulated the Association on the excellent arrangements which had been made for the meeting, and the programme which had been provided. He referred in the highest terms of commendation to the part taken by the members of the medical profession during the recent rebellion in the Northwest. He had had every opportunity of judging in the matter, and was highly pleased with the admirable manner in which the sick and wounded had been cared for. The different ambulance corps which had been formed were most useful, and had assisted most materially in the campaign. The surgeons had performed their work in a most excellent manner, though very often they were met with most discouraging circumstances, and were compelled to do their work in places not at all adapted for surgery. He concluded his address with a high compliment to the President-elect, whose scientific attainments had given him a world-wide fame.

Dr. William Osler, Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia, formerly Registrar of McGill College, Montreal, was then introduced as the President-elect, and delivered the annual address. It was an eloquent and highly interesting sketch of the history and progress of medical education in Canada.

The Secretary read a communication from Dr. Brodie, President of the American Medical Association, expressing regret at his inability to be present at the meeting,

and assured the Association that the arrangements for the coming meeting of the International Medical Congress were most complete, and that, notwithstanding the opposition met with, the meeting would be a great success. The wish was also expressed that the members of the medical profession in Canada would unite in promoting the success of the Congress.

The Association was then divided into sections.

In the Medical Section, Dr. Harrison, of Selkirk, Ont., was elected chairman, and briefly addressed the meeting. Dr. Grant, of Ottawa, read a highly interesting account of a case of aortic aneurism, illustrated with an exhibition of the specimen. The case had been under his care for over four years before death. The only treatment adopted had been complete rest and the occasional administration of large doses of potassium iodide. The exhibition of the pathological specimen was most interesting. Dr. Worthington, of Clinton, read a paper on cerebro-spinal meningitis, and Dr. Arnott, of London, presented a contribution on "The Sources of Malaria." Dr. Holmes, of Chatham, read a paper on "Observations on Puerperal Mania," and cited several cases in which it seemed that laceration of the cervix uteri was the source of the trouble. In these cases, as soon as the laceration was repaired recovery began. This paper was received with great interest, and the cases related by Dr. Holmes were certainly carefully reported.

In the Surgical Section, Dr. Edwards, of London, was elected chairman, and after a few appropriate remarks introduced Dr. J. H. Carstens, of Detroit, who read a paper giving an account of a successful case of fibroid removed by laparotomy. Dr. Fulton, of Toronto, presented a paper on "Subperiosteal Amputation," and Dr. Shepherd, of Montreal, read a paper on "Excision of the Tongue, with Preliminary Ligature of the Linguals." The cases cited by Dr. Shepherd, as well as his method of operating, were most interesting, and excited considerable discussion, in which Dr. McGraw, of Detroit; Dr. Grant, of Ottawa; Professor McLean, of Ann Arbor, and others took part. Dr. Gardner, of Montreal, presented an interesting case of double uterus, the history of which was full of interest. The specimen was exhibited and excited considerable curiosity.

The members of the medical profession in Chatham tendered to the members of the Association and their guests a splendid banquet in the Garner House on Wednesday evening. The chair was occupied by Dr. Holmes, of Chatham, who presided in a most acceptable manner. The after-dinner addresses were most eloquent, and those delivered by the American visitors produced an impression which will be remembered with pleasure. The responses to the different toasts brought out the fullest expression of the good feeling that exists between the profession in Canada and the United States.

The first order of business on Thursday morning was the election of officers for next year. The recommendations of the Nominating Committee were unanimously adopted, and were as follows: President, Dr. Holmes, Chatham; Vice-Presidents—for Ontario, Dr. Sloan, Blyth; for Quebec, Dr. Colin Sewell, Quebec; for New Brunswick, Dr. Earl, St. Johns; for Nova Scotia, Dr. Wickwin, Halifax; for Manitoba, Dr. Butt, Winnipeg; General Secretary, Dr. J. Stewart, Montreal; Treasurer, Dr. Sheard, Toronto; Local Secretaries—for Ontario, Dr. Wishart, London; for Quebec, Dr. Bell, Montreal; for New Brunswick, Dr. Lunan, Campbelltown; for Nova Scotia, Dr. Almon, Halifax; for Manitoba, Dr. Good, Winnipeg. Quebec was chosen as the next place of meeting.

In the Medical Section, Dr. Graham, of Toronto, presented a pathological specimen from a case of dissecting aneurism of the thoracic and abdominal aorta. The specimen was carefully examined. Dr. Wilkins, of Montreal, read a paper of a highly interesting character, and made an exhibition of specimens—microscopical and macroscopical—illustrating the infectious character of tuberculosis. Dr. Stewart, of Montreal, presented a paper on the curability of the chronic form of infantile paralysis (polio-myelitis anterior chronica), which was most interesting. Galvanism was the only treatment pursued, and the internal use of medicine was not recommended. Considerable discusssion followed the reading of this excellent paper. Dr. McKeough, of Chatham, presented in very concise form the notes of several cases of puerperal eclampsia, in which he had used pilocarpine. The conclusions arrived at were, that under certain circumstances, the use of pilocarpine was most beneficial, but that it was a remedy which experience proved should be employed with great caution. Dr. Bethune, of Wingham, exhibited an interesting specimen, showing a parasite removed from an abscess in the thigh. Dr. Whiteman, of Shakespeare, Ont., read a paper on "Pelvic Peritonitis and Pelvic Abscess."

In the Surgical Section, Dr. J. Campbell, of Seaforth, who was unable to be present, forwarded a paper on "Trephining of the Mastoid." It was a report of a case in practice where a young boy had disease of the mastoid cells, accompanied by the usual symptoms, the attacks each time becoming more severe than the preceding one. The doctor trephined, using a gouge guarded by the finger in the operation. He dusted the wound in both bone and flesh with iodoform, and put in a leaden tube and left it three days, after which he syringed with carbolic lotion 1 to 40. The case was entirely successful; the boy's health and hearing improved, and the perforation in the drum-membrane healed up. The principal points made by the doctor were the following: 1. The operation should be performed early. 2. The gouge, used with a rotary motion and protected by the finger, is the safest and best instrument for perforating the bone. 3. The usual linear incision should be made exactly at the union of the cartilage of the ear with the scalp, commencing on a level with the upper wall of the meatus, and the bone perforated immediately beneath this. 4. The mastoid cells should be opened freely into, and numbers of them broken up. 5. With the foregoing precautions the operation was both safe and successful. 6. The operation advised by Dr. Sexton, of New York, should never be performed. Dr. Atherton, of Toronto, read the notes of two successful cases of laparotomy performed for the removal of uterine myoma. An interesting discussion followed. Dr. Rutherford, of Chatham, presented an interesting paper on "Suprapubic Urination." A number of papers were of necessity read by titles.

The Association adjourned on Thursday afternoon. The attendance at the different meetings was large, and the great success of the gathering was most gratifying.

Reports of Societies.

British Medical Association.

FIFTY-THIRD ANNUAL MEETING.

Held at Cardiff, on Tuesday, Wednesday, Thursday, and Friday, July 28, 29, 30, and 31, 1885.

REPORTS OF SECTIONS.

SECTION OF MEDICINE.

(Continued from page 275.)

FRIDAY, JULY 31ST—THIRD DAY

THE PRESIDENT took the Chair at 11 A.M., and the Section sat until 2 P.M.

DR. W. P. BIDEN read a paper on "The Climate of Hyères," a pleasant little town, and the one on the Mediterranean most easily reached, as it is not far from Toulon. The air is dry, bracing, exhilarating. There is plenty of sunshine. Orange trees are abundant, so are olives. For the last twenty years the place has been growing in importance as a winter health resort for persons in delicate health.

DR. F. W. PAVY, read a long and rather tedious paper on "Cyclic Albuminuria," by which he appeared to mean what is often termed intermittent albuminuria. It may occur in the apparently healthy, is, in fact, only temporary, but he wished to show that it observed definite periods—would be present, for instance, in the afternoon but not in the morning. This was important as to life assurance. A case was named, which the examiner of the office rejected as albuminuric, but who was subsequently passed by going for examination at the time of day when no albumen could be detected. A number of cases were read and details given, which excited some impatience, and one member said to his neighbor in your reporter's hearing, that a man who took up more than an hour the day before ought not to take an hour again.

THE PRESIDENT thought it very important to settle whether temporary albuminuria should be a cause of rejection for life assurance. He had often been himself called upon to decide this question, and it was to be observed that there was no time to watch the case and let events decide the import of the phenomenon. The office wanted an opinion—shall this life be taken?—and wanted it the same day. He asked Dr. Pavy a question as to the significance he attached to this albumen.

DR. PAVY replied to this simple question by relating another case, which he said had been also seen by Dr. Fothergill, who was present and could state his view.

THE PRESIDENT having asked Dr. Fothergill if he would like to remark upon the matter,

DR. FOTHERGILL said emphatically that he was very glad to observe that Dr. Pavy displayed an inclination to join those who rejected the prevailing notions. For his part he welcomed the help of anyone who would assist to lay the axe to the root of the tree of that demoralizing superstition that albumen was essentially a kidney disease.

DR. BARR, of Liverpool, thought that we should look to the circulation as much as to the kidney, or more. The propelling power of the blood must drive it through the glomeruli, and any failure to do this might result in the transudation of albumen. This mechanical transudation surely had more to do with the heart than the kidney. As to the danger of temporary albuminuria, he mentioned the case of a gentleman who had passed considerable quantities for some eighteen months, but recovered, and now, years after, was in excellent health.

DR. J. D. DAVIES, from Australia, having been asked by the President if these cases were common in the colonies, said that they were very frequent, and added, that he examined many for life assurance, and had hitherto felt obliged to reject them. He would be glad if this point were further cleared up, for what otherwise could he do than continue to reject them?

A MEMBER, whose name the President did not announce (in fact few names were distinctly announced—a very inconvenient thing for reporters, however it may seem indifferent to acquaintances of speakers) said he had observed that salts were always present at the same time, often phosphates. These were common in solicitors and others, whose work was mental and who took too little exercise. Some mechanical workers would get urates when overdone. Rest would clear off phosphates, urates, or oxalates, and the albumen with them.

DR. BULKLEY, of New York, could corroborate Dr. Fothergill from his personal experience. In 1868 he had himself had a severe attack of albuminuria. Casts were present in his urine in great variety and it became quite solid on the usual tests. He took a holiday and this passed away. He returned to hospital work and in a month had another attack. He rested again and got better. On returning to work the albumen again appeared. He went to Europe and recovered. He found in different parts of the day it occurred for some time, but he was now in perfect health and protested against the notion that albuminuria is not recovered from.

DR. TYSON said he could add a similar personal experience, for years ago he consulted the President as to albuminuria, which had attacked him after scarlet fever. He had fairly recovered, but still felt a degree of susceptibility. For example, exposure to a draught would always give him a pain in the left loin. The same pain would come on if he ate much meat. He believed his left kidney had been affected but was now well, though rather weak. He had come to the conclusion that with care he could do his work very well, and he was determined, above all things, not to have his urine examined again, for he did not believe it now contained albumen. [Laughter and applause.]

DR. GRIFFITH, of Swansea, said he thought the kidney was very much like other organs. One has one disease, and another has another. He attributed albuminuria to derangement of the vaso-motor centre. But if a certain quantity of albumen was persistently present in the urine he thought there was certainly something wrong with the kidney.

THE PRESIDENT, DR. WILKS, said he regarded Dr. Bulkley's and Dr. Tyson's cases as instances of real recovery from a definite disease.

A MEMBER, whose name was neglected to be given, said that five years ago he had pain in the region of the kidneys which laid him up for three weeks. It was so severe he feared it might arise from grit, though he also thought of gout. He completely recovered, and has experienced no difficulty about his food, but if he drinks a glass of beer or any stimulant he at once gets albumen in his urine.

DR. PAVY replied, commenting on several of the statements made, but said nothing he had not previously stated, save that he had not found anything special about phosphates or other salts.

The discussion was now closed, and the papers proceeded with.

DR. J. F. PAYNE, read a paper on

ALBUMINURIA COMING ON IN THE COURSE OF SECONDARY SYPHILIS,

full of matter carefully arranged, and to which justice cannot be done in a short report.

DR. COUPLAND read a paper on

PULMONARY GANGRENE,

and DR. T. D. GRIFFITHS another on

THE CAUSES OF THE LOCALIZATION OF TUBERCLE IN THE APEX OF THE LEFT LUNG.

Some remarks were made and questions asked in reference to points treated in these two papers, but there was no definite discussion, and the President called on

Dr. Prosser James to read his promised paper on "Pancreatic Digestion." This opened by an account of the physical and chemical characteristics of pancreatic juice when fresh from a recent fistula as contrasted with the secretion of a later period. This was followed by an account of the several ferments found in the juice, and the attempts made to isolate them, and this again by reference to the so-called pancreatines. The author produced some sensation by the announcement that sometimes, through insufficient care or skill in preparation, the ferments were not merely destroyed, but that decomposition had been suffered to set in, and that he had known the changing products of decay to do duty for the pancreatic ferment. The idea was disgusting and the consequences probably injurious. Dr. James then gave the results of his own experiments, and announced that he had succeeded in separating all the ferments in combination with an inorganic, and, therefore, stable compound. This was no other than chloride of sodium, which he had some time ago combined with pepsine. He replied to some *à priori* objections to the use of salt for this purpose, and said he hoped shortly his pancreatic salt might be made on a larger scale, and prove as useful as his "peptic salt" had done. He had placed specimens of these, as well as the products of other experiments of his, in the annual museum, where members could examine them for themselves. The remainder of this paper was occupied with the process of secretion of pancreatic juice, and the question whether there are any therapeutical means for influencing it, but the author read this so rapidly, no doubt because time pressed, and omitted some paragraphs, that it was difficult to follow.

The President remarked that the paper hardly invited discussion, unless any one had come prepared for the purpose, and would have to be read carefully in the *Journal*.

Dr. A. T. Harrison read a paper on the "Treatment of Tinea Tonsurans."

Dr. Milner Fothergill submitted to the Section, in his striking and agreeable style, the semi-paradoxical question

WHEN A PATIENT DIES OF EXHAUSTION, OF WHAT DOES HE DIE?

This might be supposed likely to produce an amusing discussion, but time was wanting. A general meeting was to immediately follow the sitting of the Section, to which some were bound to go. Lord Windsor's garden party would soon begin, yet the Section was in earnest and proceeded with the work. The following papers were either read, or their conclusions stated by the authors, or in some cases taken as read: Mr. G. Padley, "Case of Empyema Successfully Treated by Operation"; Dr. Shingleton Smith on "Intra-pulmonary Injections"; Dr. Tatham, "Registration of Chest Diseases as Carried on at Brompton Hospital"; Dr. Myrtle, "Syphilitic Eruptions and their Treatment by Mercury and Harrogate Waters"; Dr. Drummond on "Malarious Melanæmia and on the Influence of Geographical Position on Fever"; Dr. Haddon on "The Tropical Sea as a Health Resort in Pulmonary and Renal Diseases"; Dr. Harper on "Extraordinary Cornea in a Child" and "Abnormal Shape of Skull."

Some other papers announced in the programme of previous days, but not mentioned in the foregoing report, were taken as read, and will appear in the *Journal*.

The President then closed the Section of Medicine.

Making Business for the Alienists.—An Australian journal thus announces a forthcoming serial novel: "Of 10,000 readers of this fatal romance it is estimated that there were 422 cases of insanity, 977 of monomania, 894 suicides, and 1,315 cases of mysterious disappearance."

THE BERLIN SOCIETY OF INTERNAL MEDICINE.

Stated Meeting, June 1, 1885.

Herr Fraentzel in the Chair.

(Special Report for The Medical Record.)

Herr Remak presented a patient suffering from

DEGENERATIVE MUSCULAR ATROPHY.

The man, now thirty-five years of age, had had a hard chancre, twelve years before, followed shortly by an eruption of roseola. He had been married for eight years and was the father of two healthy children; his wife had had two still-births and one miscarriage. She had also been treated for syphilitic ulcerations. Six months ago the patient began to complain of pain in the neck and right shoulder, and of hoarseness in speaking. He had also had several exostoses, all but one of which had disappeared under treatment by iodide of potassium. Inspection showed considerable atrophy of the muscles of the neck and intrascapular space, of the trapezius, and of the muscles of both arms, especially the left. The diaphragm was also implicated, as evidenced by the epigastric sinking during a deep inspiration. Laryngoscopic examination revealed paralysis of the left recurrent nerve, and subsequently of the right also. The muscles of the palate and tongue were unaffected. Sensation was unimpaired, and the condition of the lower extremities and of the genito-urinary organs was normal. The author believed that there was an ascending lesion of the cervical enlargement leading to degeneration of the muscles which derive their innervation from that portion of the cord.

Herr P. Guttmann presented two specimens of

ANEURISM OF THE AORTA.

The first case was that of a man, fifty-six years of age, in whom there was flatness on percussion in the posterior and lateral portions of the left side of the chest. There were no signs pointing to a lesion of the heart or great vessels. Within twenty-four hours after coming under observation the patient had an attack of syncope, accompanied by a frightful hemorrhage from the mouth, and died immediately. The autopsy revealed an aneurism of the aorta, the size of a man's fist, at the level of the fourth dorsal vertebra. There was a communication with the œsophagus whence had come the hemorrhage that killed the patient. There was no atrophy of the left ventricle. The second case was one of aneurism of the arch of the aorta, which was readily diagnosed during life by the physical signs and by the evidences of pressure upon the neighboring structures. The autopsy showed the correctness of the diagnosis.

Herr Klaatsch then read an interesting paper on

RÖTHELN,

or German measles. After a historical review of the subject the speaker proceeded to describe the disease as he had observed it in two distinct epidemics. He found that a previous attack of measles or scarlatina afforded no immunity to rötheln. The symptoms were those of a benign affection of short duration. The eruption appeared first upon the upper portions of the body and extended thence downward; in some cases it covered the entire body, even the scalp and palms of the hands, in other cases it was limited to a smaller area. The skin was covered with spots of a bright red color, varying in size from mere points to patches one-fourth to one-half inch in diameter, equidistant from each other and separated by healthy integument, though sometimes the eruption was confluent. The eruptive period was from three to five days in duration. In about half the cases there was no fever; in the others the temperature averaged about 100° F. In some instances there was redness of the conjunctiva and pharynx, and the author occasionally observed a swelling of the cervical glands. The affection

was moderately contagious. The period of incubation was difficult to determine, but seemed to be usually from seventeen to twenty-eight days. It was not necessary to isolate patients with rötheln for a longer period than eight days.

The Society then adjourned.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

DOCTORS AND THEIR ANNUAL HOLIDAY—A REMINISCENCE OF SIR ASTLEY COOPER—THE RELIGIOUS QUESTION IN HOSPITALS—THE STATE OF THE THAMES—PURIFICATION OF THE SEWAGE—DIARRHŒA MORTALITY.

LONDON, August 17, 1885.

As most of the leaders in medicine and surgery are away taking their annual holiday, scientific medical work may be fairly said to be now carried on in London at the minimum rate for the year. The annual holiday has now become an institution for doctors as well as patients, and the present is the month chiefly favored by both. Some medical men contrive to combine business with pleasure, and select some continental health resort for an annual visit where they can take some of their patients with them. Few doctors are indifferent to fees, and they are usually as attractive to those who enjoy large practices as to those who vegetate on small ones. I fancy very few modern hospital surgeons in London would be tempted to imitate Sir Astley Cooper's behavior on one occasion. A distinguished orthopedist (still living and from whom I have the story) called on Sir Astley one morning by appointment at his request, to demonstrate to him a then new operation. More than an hour elapsed and Sir Astley was still busy with questions and remarks, being, says my informant, a man "always very keen after knowledge." The servant came several times to the door to remind him that numerous patients were waiting, but was put off time after time. Midday at last arrived and with it the surgeon's carriage to take him to his hospital. The footman again entered and announced the carriage. Sir Astley Cooper was rather taken aback for a moment, but recovering himself, said: "Bring the carriage round to the stable entrance and I will go out through the stable." This he did, leaving all his patients to go away without his having seen one of them. On leaving, he invited his friend to come again on the following day and renew the demonstration.

The religious question is again to the front in connection with hospital management. This time it is at University College Hospital where a scandal has arisen, owing to a dissenter having been refused admission to train for a nurse in that institution. The nursing in University College Hospital is conducted by a "sisterhood," who all belong to the Church of England and have pronounced tendencies toward the "High-church" party. The placing of the nursing in the hands of a "sisterhood" and giving them exclusive control has been tried at other hospitals, and in them also it has led to trouble. King's College Hospital was the scene of angry disputes some time back, and the more recent feuds at Guy's can scarcely be forgotten. The delegation of the nursing at University College Hospital to a sisterhood belonging to the ritualistic party is the more remarkable because University College (and subsequently the Hospital also) was founded mainly by the exertions of Nonconformists, and the necessary funds were largely contributed by them. The English universities were then closed to Dissenters, as also was Trinity College, Dublin. As a protest against this the present College in Gower Street was founded. Out of this sprang the present University of London. I am not speaking without book, as it were, for a near relative of my own took, in conjunction with the late Lord Brougham and others, a very active part in founding the College. As no expression of religious belief was exacted from its students it was called "The Godless College" by the students of its rival in the Strand—King's College. "The Godless College," however, prospered, and is still largely supported by Nonconformists. Some of its professors and some of the medical staff of the hospital at present are, I know, dissenters. I need not dwell further on the subject. I have said enough to show that, great as have been the advances within the last fifty years, we are still far from enjoying complete religious liberty. In this, as in some other things, America is ahead of England. The Hospital Sunday Fund threaten to withdraw their grant unless the exclusiveness to which I have referred is modified.

The usual autumnal scare about the state of the Thames is now on. Its condition is certainly not one of which we can be proud. Although the metropolitan sewage is discharged some miles down the river, yet the tidal efflux carries polluted water far up into the intrametropolitan portion of the stream. During the present summer large quanties of manganate of soda and sulphuric acid have been used as disinfectants and deodorants. These have been freely poured into the sewers, and also used at the outfalls. The cost per week has been over three thousand pounds. As yet only a million gallons daily have been treated at the outfalls, but preparations are being made for treating eight million gallons daily. It is proposed that a portion of the sewage shall be treated by precipitation or otherwise on one of the islands of the Thames before being allowed to pass into the stream. In spite, however, of the unsanitary state of our river, the returns of the Registrar-General show the present mortality from diarrhœa in London (during the past few weeks) is equal to an annual death-rate of less than four per thousand. This is less than at most provincial towns, and is very greatly exceeded by that of most foreign cities.

OUR PARIS LETTER.

(From our Special Correspondent.)

THE PROPERTIES OF TERPINOL—THE POSSIBILITY OF THE PASSAGE OF BACTERIA FROM MOTHER TO FŒTUS—SUBCUTANEOUS INOCULATION OF TYPHIC MICROBE—MORE CONCERNING CHOLERA INOCULATION.

PARIS, August 14, 1885.

About six months ago Dr. Dujardin-Beaumetz read a paper at the Société de Thérapeutique of Paris, on the properties of terpinol, a derivative of terpine, which latter is nothing else than the binhydrate of turpentine. Dr. Lépine, of Lyons, experimented with both these substances on hospital patients, and both these gentlemen came to the conclusion that the substances just named are most useful in bronchial catarrh. Professor Germain Sée has since experimented with terpine, and as his experience is not quite in accord with that of Dr. Lépine as to its physiological effects, he has thought proper to give the results of his own researches, which he laid before a recent meeting of the Academy of Sciences. The following is a summary of the learned professor's conclusions on the subject: 1. Terpine constitutes a powerful modifi cator of the mucous membrane of the air-passages, the excessive secretion from which it keeps under control. It diminishes and rapidly stops purulent expectoration in the catarrhal forms of phthisis, whether the muco-purulent secretion comes from the bronchial tubes irritated by tubercles or from the parietes of pulmonary cavities, whether the disease is at its commencement or at the stage of cavity-formations, terpine will be indicated whenever the formation of pus is sufficiently abundant to fatigue the patient, to reduce his strength, or to bring him to a state known by the term consumption. 2. It may be successfully employed in the hæmoptysis of commencing tuberculosis, that is to say, when the disease has not reached the development of large cavities with aneurisms of the pulmonary artery. 3. In the treatment of pul-

monary catarrhs, of chronic bronchitis independent of asthma, and the provoking of dyspnœa only by the blocking up of the bronchial tubes, terpine constitutes the best means by which the bronchial hypersecretion may be diminished. 4. Its prompt and certain action and being exempt from physiological inconveniences renders it preferable to the preparations of turpentine, of tar, or of other substances of that class which contain so little of terpine; the essence of turpentine is not tolerated by the stomach. Terpine even presents, owing to its perfect innocuousness and its perfect digestibility, advantages over creasote. 5. The best mode of administering this drug is in the form of pills or in an alcoholic solution, and the best dose is one gramme, or fifteen and a half grains per day. 6. In nervous emphysematous or catarrhal asthma, iodine and pyridine are incontestably superior.

A short time ago M. Koubassoff made a communication to the Paris Academy of Sciences through M. Pasteur giving an account of some experiments he had performed to illustrate the possibility of the passage of bacteria from mother to fœtus. He injected various cultivations of the bacillus of carbon under the skin of pregnant guinea-pigs. On examining the fœtus after the death of the mother it was found that the bacilli always passed from the mother to the fœtus, but that pathological conditions of the membranes of the placenta and fœtus prevented this passage. That inoculation of pregnant females with a too powerful vaccine nearly always caused the death of the fœtus; that inoculation after the mother had been protected by satisfactory vaccination nearly always killed the fœtus. From these facts M. Koubassoff concluded that the fœtus cannot be protected by maternal inoculation.

At a subsequent meeting a paper from the same author was read on the passage of the septic vibrion of the rouget and tubercular bacilli from the mother to the fœtus. He remarked that if the bacilli of the septic vibrion inoculated into the mother be found in the fœtus, one is induced to admit as very probable the passage of all microbes from the mother to the fœtus, and to suppose the existence, in the placenta, of direct communications between the vessels of the mother and of the fœtus. From these experiments M. Koubassoff concludes that the bacilli of the septic vibrion of the rouget and of tuberculosis also pass from the mother to the fœtus. The importance of this fact, if proved, cannot be overrated.

At the same meeting of the Academy of Sciences, M. Tayon read a note on the results of experiments performed on himself and on several persons who volunteered themselves for the purpose, which permitted him to affirm that the subcutaneous inoculation of the typhic microbe is not fatal in man; but whether this would confer immunity against typhoid fever is a question that he is not in a position to resolve, and must therefore leave it to others to do so.

In connection with preventive inoculations I may mention that M. Anglade forwarded a paper to the Academy of Sciences, signed by three physicians, giving an account of Dr. Ferrán's inoculations performed by him at Belfajo, and other documents have been promised by other Spanish physicians of the results obtained by them at the different localities at which similar inoculations were practised by them.

Dr. Paul Gibier, of Paris, and Dr. Van Ermengen, of Brussels, have just terminated a certain number of experiments which show that hypodermic injections of the cholera bacillus, even of a strong dose, do not prevent animals dying after they have been inoculated by the stomach. This must militate greatly against Dr. Ferrán's theory, who, however, is allowed to continue his inoculations on his own responsibility.

A delegation composed of MM. Peyron, Director-General of the Assistance Publique, and Michelin, President of the Municipal Council of Paris, accompanied by Drs. Desprès and Robinet, as well as by two or three other members of the Council, has proceeded to London to study the organization of the work-houses, fever hospitals, and other hospitals set apart for patients affected with contagious diseases.

ON THE REPORT OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION—A REPLY TO DR. STERNBERG.

To the Editor of The Medical Record.

Sir: I very much regret that the Chairman of the Committee on Disinfectants of the Public Health Association has thought it best to reply to the criticisms of Mr. McClintock and myself by certain personal remarks, that, even if true, would not have any bearing on, or affect in any way the truth of our statements. I think that every one will admit that this evidence of petty spite is unworthy of a scientific investigator, and if Dr. Sternberg thinks it a waste of printer's ink to discuss publicly the report of the committee, he should not use it to bring before the public personal details. However, since he has descended to a discussion of this character, he will find that I am by no means averse to it; except that I am sorry to take up valuable space with such matter, and would not be led into it except to defend myself from gross misstatements.

I desire to offer the following commentary on Dr. Sternberg's article, and I wish it distinctly understood that nothing is said by way of malice, but simply to correct the charges he has made.

As regards the report being a preliminary one, this fact was especially mentioned by us, and we stated that we considered the objectionable recommendations as simply evidence of hasty preparation. Besides, while lack of time would justify an incomplete report, it does not justify an erroneous one.

The criticisms were not made directly to Dr. Sternberg for several reasons. I did not see the report until it had been published both in the *Medical News* and in pamphlet form, and in this way given a wide circulation. The fact that my name had been associated with the work on which it was based seems to me to be sufficient reason for my interest in its correctness, rather than requiring my silence. Perhaps my principal reason for not communicating directly with Dr. Sternberg was that I felt convinced that any criticism made in this way would not reach the profession. I know that this statement requires explanation, which I can give only by citing a past experience.

Not very long since Dr. Sternberg published in the *American Journal of the Medical Sciences* some determinations of the germicidal value of certain agents, among which were zinc chloride and Squibb's liquor zinci chloridi. It was stated that two per cent. of the solid chloride was efficient, and that eight per cent. (this was by volume) of Squibb's solution failed, the same conditions being observed. Now this solution is warranted to contain fifty per cent. of zinc chloride, and has a specific gravity of about 1.5, so that this eight per cent. by volume was equal to twelve per cent. by weight, one-half of which was solid zinc chloride. Professor Roberts Bartholow, in a note in the *Medical News*, called Dr. Sternberg's attention to this great discrepancy in his results. Dr. Sternberg then obtained a second bottle of Squibb's solution, and asked me to make a determination of its germicidal value, which was found to agree pretty closely with his own. He then replied to Professor Bartholow, saying that he considered his methods sufficiently accurate to justify the belief that Squibb's solution was not of full strength. It will be seen that to harmonize his two results it would be necessary for this preparation to contain less than one-third of the amount of zinc chloride warranted by Dr. Squibb. Thinking this to be extremely improbable, I determined by analysis the amount of this salt present, and found it to be just fifty per

cent. I informed Dr. Sternberg of this, but I have waited in vain for him to publicly correct his error. Now I have not cited this to show that Dr. Sternberg made a mistake, for none of us are free from them, but to show why I adopted the method I did of correcting the errors in the report of the committee.

It is true that the disinfecting and antiseptic powder was withdrawn before the publication of our paper, but not until some time after it had left our hands. The note to which Dr. Sternberg refers stated not only that the powder was withdrawn, but that the solution containing potassium permanganate should be decolorized by the addition of a little chloride of lime or Labarraque's solution before use on clothing or walls. The following history of the article, by McClintock and myself, may throw some light on the appearance of this note. As the report of the committee was published in the *Medical News*, we thought it proper that, as it is customary, any criticisms should appear in the same journal. For this reason our paper was first sent to this journal. Not long afterward I happened to be in Philadelphia and called on the editor of the *News* in reference to the article. I found that it was in type ready to go to press, but was surprised to be told by the editor that he had changed his mind, and thought it best not to publish it. The reasons assigned for this were "that it would cast doubt on all the committee had done," and "that Dr. Sternberg's note had just appeared in the number of the journal issued that day." As to the first of these I assured him that, as stated in our article, we had no such intentions; and as to the second, I pointed out to him a dangerous error in the attempted correction, viz., that chloride of lime or Labarraque's solution would *not* decolorize the potassium permanganate in the solution, while it would precipitate the mercuric chloride, and in this way entirely destroy the value of the solution. I was at a loss to account for this rejection of our article after it had been put in type, and the sudden appearance of Dr. Sternberg's note, until later, when, in answer to a letter from me, the editor of the *News* admitted that he had informed the committee of the intended publication of the criticisms. Now, I cannot say that this caused Dr. Sternberg to write his note—of this every one is at liberty to have his own opinion. The action of the editor of the *Medical News* would also bear discussion, but this is not the proper place for it.

There is one other point connected with this note that deserves attention. If, as Dr. Sternberg claims in his latest, the permanganate solution does not stain clothing, and if, as he adds, "this possibility of staining was fully considered by the committee before the recommendation was made," what was his object in rushing out with a note saying that this color should be bleached out before use? This part of his note he does not refer to in his last paper. Questions of this nature are not decided by consideration, but by experiment, and every one interested can determine for himself whether or not the solution recommended will, under ordinary conditions, give a decided and indelible stain to white goods after two hours' immersion, as directed by the committee. The fact is, that rather than admit their error the committee seem inclined to add the color as first directed, and then to get it out in any way possible. If one will trouble to use impure water, as Dr. Sternberg suggests, this will probably remove the permanganate better than chloride of lime, and it also possesses the advantage of not precipitating the mercury.

I am not sorry that it becomes necessary for me to explain my connection with the work of the committee. The first of last December Dr. Sternberg asked me to join him in the work, to which I agreed, with the distinct understanding that I would only give what time I could spare from other experiments, and that whatever was published should be over both our names. The work was continued for about two months, when I gave it up of my own accord, at which Dr. Sternberg very kindly expressed his regrets. I did this simply because I preferred to publish my work independently, and not to have it thought that it was done under any one's advice or directions. My work on the hypochlorites was done at the expense of the committee, and to some extent by what is known as Sternberg's method; but it was taken up of my own accord, and carried out according to my own plans. My attention was first called to the value of this class of preparations by the commercial samples of Labarraque's solution I examined for the committee. Dr. Sternberg speaks of the use of his method as though he had a proprietary right in it. He might very well consider how much credit he gives to Koch and Pasteur for the constant use of methods devised by them. If better proof is needed to show that he considers his method of the cultivation of bacteria private property, it lies in the fact that during this work he required a "trusted assistant" to promise that if his services were asked for by a certain distinguished investigator he would not give them, as that gentleman was anxious to secure some one acquainted with his methods of work, and thus do work for which he (Dr. S.) ought to have the credit. We would suggest that this could be avoided by taking out a patent on his method, or at least he should never have published it.

The statement about my commercial work is so untrue as to require but little notice. More than a month after I had given up all work for the committee I was asked by a manufacturing firm to give some chemical advice about the manufacture of a disinfecting solution, and of course I complied with their request. The subject was not mentioned to me until March, while I gave up work for the committee in January. This statement can easily be verified by reference to the firm to whom the advice was given. From this it must be seen that the intimation that my services were dispensed with on account of my commercial work is absolutely false. I do not engage in investigations having secret "points." The prejudice of the committee against manufacturers did not cause them to refuse money from such as had been benefited by their report, and it was even intimated to me by one of them that a contribution from the firm that had asked my advice would be acceptable, since the report was in their favor. Had they received it, perhaps my commercial work would not have been so objectionable. I do not mean that this money was allowed to influence their report, but was simply used to carry on the investigation.

Dr. Sternberg seems to still insist on the point that mercuric chloride should be added to "whitewash" for disinfecting walls. It was not claimed by us that the yellow oxide of mercury formed would color the walls, for the lime is present in too great excess; but if he doubts that it is formed, he can easily consult some elementary text-book of chemistry.

Any one having read the report of the committee will see that there is no intimation that mercuric chloride should be dissolved before it is placed in vaults; and, in fact, this looks very much like an after-thought on the part of the chairman of the committee.

The committee claim, and Dr. Sternberg admits in his reply, that the *only* advantage of the hypochlorite solution is its rapid action. We merely called his attention to his former statement about the coagulating action of corrosive sublimate to show his inconsistency in stating that it was equally effective on longer action. We referred only to the use of these agents in the sick-room, but his former statement that mercuric chloride should not be used "when the germs to be destroyed are embedded in masses of albuminous material," seems to me to apply more especially to the material in vaults. It is not sufficient, as Dr. Sternberg argues, to use, under such circumstances simply an antiseptic, for many vaults or cesspools communicate, with underground watercourses, and by this means the germs present would be removed from the restraining influence of the antiseptic, and contaminate the water used for drinking purposes. That the

pump-water in some of our largest cities is in pretty direct communication with cess-pools is shown by analysis. Dr. Sternberg's experiment, in which the solution was stirred up with a little *semisolid* fæces in a beaker, can scarcely be held as applying to the masses in vaults, and which are to be estimated by the five hundred pounds.

The criticisms that have been made do not derive their force from the names of either Mr. McClintock or myself, but if they have any, from the fact that they are just. We leave the profession to judge of this, feeling that they will do so without regard to name or position.

J. R. Duggan.

August 24, 1885.

COINCIDENT CEREBRATION.

To the Editor of The Medical Record.

Sir: *The Lancet* for August 15, 1885, contains a communication from "Nelson B. De Sizer, M.D. and Bac. Sc." (Neo-Eboracensis), dated "Brooklyn, New York, August, 1884," on the comparative danger of various anæsthetics. With the exception of the four introductory lines, the letter is an almost literal transcript of the seventy-ninth page of a work on "Artificial Anæsthesia and Anæsthetics," published by William Wood & Co., A.D. 1881. Of this republication of those statistics in the form of an original article, I do not now complain; but I do regret that the gentleman did not improve the occasion by adding to those figures, whose collection cost me so much labor, a new series of observations compiled from the literature that has accumulated during the past five years—a literature to which I have not access. I remain, Sir, yours truly,

Henry M. Lyman, A.M., M.D.

Chicago, Ill., August 27, 1885.

RHUS AROMATICA IN THE TREATMENT OF ENURESIS.

To the Editor of The Medical Record.

Sir: Since the publication of the brief article in The Record of July 25th on rhus *aromatica* (not rhus toxicodendron) in the treatment of enuresis, I have received a number of letters from physicians in different parts of the country, asking for further information in regard to the remedy. For the benefit of those interested I will say that my experience with the drug has been confined chiefly to the treatment of children. For a child ten years of age I usually prescribe ten or fifteen drops—of a reliable fluid extract—three or four times a day—say a dose after each meal and at bedtime, to be given in a little glycerine and water, or other suitable excipient. No special nicety need be observed in regard to dosage, as it is regarded as harmless if given in any quantity which an intelligent physician would be likely to prescribe. In reply to your Boston correspondent (see Record of August 15th), I will say that I wrote rhus *aromatica* in the text of the article of July 25th, and either the editor of The Record or the printer supplied the headline, and erroneously wrote rhus *toxicodendron*. So far as I know the latter drug is of no benefit in enuresis. The good effects of rhus aromatica are usually manifested quite promptly—frequently giving relief within the first two or three days. I have also found the drug useful in the diarrhœas of both adults and children arising from intestinal indigestion.

Those desiring further information can obtain the same by referring to the *Therapeutic Gazette* for May, 1882. Yours respectfully,

George W. Willeford, M.D.

Glendale, Ind., August 20, 1885.

The Family Doctor.—Little Boy: "Please, I want the doctor to come and see mother." Servant: "Doctor's out. Where do you come from?" Little Boy: "What! Don't you know me? Why, we deal with you. We had a baby from here last week!"

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 30, 1885, to September 5, 1885.

Magruder, D. L., Lieutenant-Colonel and Surgeon. Granted leave of absence for fifteen days. S. O. 210, A. G. O., September 3, 1885.

Middleton, Passmore, Major and Surgeon. Assigned to duty as attending surgeon at these headquarters, vice Major J. V. D. Middleton, Surgeon, hereby relieved. S. O. 131, Department of the Missouri, August 28, 1885.

Girard, Alfred C., Captain and Assistant Surgeon. Assigned to duty as post surgeon at Boise Barracks, Idaho Ter. S. O. 142, Department of the Columbia, August 22, 1885.

Davis, William B., Captain and Assistant Surgeon. Having reported for orders from leave of absence, assigned to duty at Fort Porter, N. Y., as post surgeon. S. O. 183, Department of the East, August 28, 1885.

Kane, John J., Captain and Assistant Surgeon. Upon expiration of his present leave of absence, to be relieved from duty at Willet's Point, New York Harbor, and to report to Commanding General, Department of Texas, for assignment to duty. S. O. 201, A. G. O., September 3, 1885.

Banister, John M., Captain and Assistant Surgeon. Assigned to temporary duty at the camp of the competitors at Creedmoor, N. Y., arriving not later than September 4, 1885. S. O. 58, Division of the Atlantic, August 31, 1885.

Richard, Charles, Captain and Assistant Surgeon. To be relieved from duty in Department of the East, and to report to the Commanding Officer, Willet's Point, N. Y., for duty at that station. S. O. 201, C. S., A. G. O.

Kendall, William P., First Lieutenant and Assistant Surgeon. (Recently appointed.) To report in person to the Commanding General, Department of California, for assignment to duty. S. O. 201, A. G. O., September 3, 1885.

Official List of Changes in the Medical Corps of the United States Navy for the week ending September 5, 1885.

Stewart, Henry. Surgeon. Leave of absence extended one year from October 15th, with permission to remain abroad.

Steele, John M., Passed Assistant Surgeon. Detached, September 1st, from Constellation, and report for duty at Naval Academy, Annapolis, Md.

Bright, George A., Surgeon. Detached, September 1st, from Constellation, and wait orders.

Dickson, S. H., Passed Assistant Surgeon. Ordered to Naval Academy, Annapolis, Md., as relief of Passed Assistant Surgeon A. A. Austin.

Fitts, Henry B., Assistant Surgeon. Detached from Coast Survey Steamer Gedney, and wait orders.

Austin, A. A., Passed Assistant Surgeon. Detached from Naval Academy, Annapolis, Md., and ordered to Coast Survey Steamer Gedney, to relieve Assistant Surgeon H. B. Fitts.

Oleum Deelinæ, or deelina oil, is the name given by Dr. John Roberts, of Chester, England, to a refined petroleum, prepared on the banks of the Dee, and which is recommended for medicinal and surgical use, on account of its greater purity than vaseline. Although it is an oil, little or no greasiness is left on its application; it is readily absorbed, has no odor, and never becomes rancid. Dr. Roberts regards it as "almost a specific" in eczema and kindred diseases of the skin.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending September 5, 1885:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.								
September 5, 1885.....	0	37	11	1	8	28	2	0
Deaths.								
September 5, 1885.....	0	10	2	1	1	18	0	0

TREATMENT OF EPISTAXIS.—Introduce into the nostril, to a considerable distance upward, a piece of fine sponge cut to the size and shape necessary to enable it to enter without difficulty, previously soaked in lemon juice or vinegar and water. The patient is to be kept lying on the face for a length of time with the sponge in place.

SCROTAL CALCULI.—Dr. Schkott, of Moscow, has recently described, in a Russian medical periodical, the case of a patient, aged twenty-seven, who, when a child, was subject to some obscure disease of the scrotum, and noticed, later on, that he apparently had developed a third testicle, much harder than the two normal glands. For seven years before he came under Dr. Schkott's care in hospital, he frequently passed blood in his urine, and for two years micturition and coitus had been attended with pain. The third testicle reached the size of a goose's egg. Three months before admission he struck the scrotum, which inflamed and suppurated. The abscess burst, and left a fistulous track. On passing a probe into the track, three hard substances, which could be moved separately, were distinctly felt. On passing a catheter, a fistula was detected in the membranous part of the urethra. The scrotum was incised, and seven uric acid calculi were found in a capsule of connective-tissue, fitting closely against each other. Dr. Schkott excised the sac after extracting the calculi, and closed the urethral fistula first with catgut, and then sutured the scrotal wound with the same material. The fistula opened up again, but was successfully closed by a second operation.—*The British Medical Journal.*

POWDERED RICE AS A STYPTIC.—It is said that powdered rice as a styptic remedy has a great effect on fresh wounds, much superior to oxide of zinc. By mixing from four to eleven per cent. of it with lint, and using the lint thus treated as a compress, it is very effectual and more valuable than subnitrate of bismuth, salicylic acid, or carbolic acid.

SALICYLIC LEMONADE.—The *British and Colonial Druggist* says that as a "hospital beverage," which has lately been found of very great value in cases of typhoid and other fevers, scurvy, and gout, the following cannot be too widely known, it having been, we understand, first devised by a late medical officer attached to the Soudan expedition: ℔ss. Fruct. limon., No. 10; acid. citric., ʒss.; acid. salicylic., gr. cc.; sacch. alb., aquæ, ää q. s. Squeeze the lemons and put the juice aside; boil the fruit in half or three-fourths of a gallon of water for fifteen or twenty minutes; after standing six hours take out the lemons, and again press them before throwing the exhausted pieces away. Add the juice and citric acid to the liquid, boil five minutes, and strain. While hot add the salicylic acid, and stir until dissolved. Sweeten to taste with the white sugar, and make up the bulk to one gallon of water. Salicylic lemonade may be taken freely, either of the strength here given, or diluted with half its bulk of water. It should be freshly made every two or three days, unless it be permissible to "qualify" it by the addition of a little pure French brandy. If required to be in "bright" condition, add, when cold, a little beaten-up white of egg, boil for three minutes, and filter. If found rather too harsh for some tastes, dissolve in the boiling liquid, before straining, half an ounce of Nelson's Patent Opaque Gelatin, previously swelled for five hours in cold water.

OVARIOTOMY IN BELGIUM.—An interesting event was celebrated by a festival at Ghent recently. Dr. Boddaert, one of the most distinguished of Belgian surgeons, having completed one hundred cases of ovariotomy received thereupon the congratulations of many of his professional brethren. Sir Spencer Wells was to have been present, but was unavoidably detained in London. A letter from him was treated as the proposal of the toast of the evening, and a reply was sent by telegraph that the company were drinking his health in bumpers of champagne. Considering that Sir Spencer Wells performed ovariotomy in Brussels for the first time in 1865, and had a successful case in Ghent with Dr. Boddaert in 1871, when the operation was still a novelty, it is not a little surprising that one Belgian surgeon should already have had one hundred cases.—*The British Medical Journal.*

ATTEMPTED SUICIDE THROUGH DRINKING KEROSENE.—A patient was recently admitted into the Lariboisière Hospital, who had attempted suicide by drinking petroleum. She suffered from an intense burning sensation in the mouth, œsophagus, and stomach. She was very excited from the effect of pain and disappointment at having failed in her suicidal attempt; she exhaled a strong odor of petroleum. Two grammes of ipecacuanha, supplemented by several glasses of milk, provoked vomiting. The vomited matter was covered by a layer of petroleum, which presented the aspect of continuous grease-spots. After an enema was administered, she had a motion, which presented the same peculiarity as the matter vomited, and also smelled strongly of petroleum. She continued to take large quantities of milk. She gradually recovered, and ate the ordinary fare. Small doses of quinine-sulphate cured the pains in her head, which had caused her much suffering, and in ten days she was convalescent. During four days she exhaled an odor of petroleum.

CÆSAREAN SECTION IN CENTRAL AFRICA.—In a recent article on the postures adopted by women in labor in Central Africa, Dr. Breitmann gives an interesting account of the operation of Cæsarean section, as witnessed by Dr. R. W. Felkin at Kahura (*The Medical Press and Circular*, July 15, 1885). The case was that of a very handsome young negro woman, a healthy primipara, aged twenty years. He entered the hut just at the commencement of the operation, but was not permitted to convince himself of the condition of affairs by examination. By the side of the half-intoxicated patient stood a quantity of banana wine. A bandage of Mbugu, a stiff material made from the bark of a tree, went over the breast, and bound the patient firmly to the bed, another passed over the thighs; an assistant held fast the feet, and another, standing on the right side, held the skin of the abdomen on the stretch. The operator, holding aloft the knife, muttered a prayer. After the completion of the ceremony he thoroughly washed the abdomen of the woman and his own hands with banana wine, uttered a piercing cry, which was repeated by those standing without, and made an incision from the pubes almost to the umbilicus, and right into the uterus, so that the liquor amnii gushed out. Some bleeding vessels were successfully touched with the actual cautery. The operator quickly extracted the child, while a second assistant drew the edges of the uterine wound apart and compressed them. After division of the umbilical cord the child was handed to a woman, the operator laid aside the knife, grasped the uterus and compressed it with both

hands with all his might. He then dilated the cervix with two or three fingers, removed the blood-clots and the placenta, while the assistants were busy in arranging the intestines, and especially in preventing any portion getting between the edge of the wound. What bleeding still continued was stopped by the actual cautery, while the operator still compressed the uterus until it was firmly contracted. No sutures were inserted. The assistant who had before held the abdominal wall on the stretch grasped the angle of the wound and the whole wound was covered with an herb pad. The bandages were now loosed, the assistant grasped the patient by the arms and turned her over into a position in which the fluid in the abdominal cavity flowed out. She was then brought back into the former position, the herb covering was removed, the edges of the wound were carefully adjusted and fixed with well polished needles, similar to acupressure needles, and made fast by an encircling thread. A paste prepared from two different roots by chewing was laid over the wound in the place of plaster, over this a previously warmed banana leaf, and the whole fastened on with Mbugu bandage. Up to the moment when the needles were inserted the patient had evinced no expression of pain, and an hour after the operation was in good spirits. The temperature did not rise above 37.5°, C. except during the first night, when it reached 39°. Pulse 108. Two hours after the operation the child was put to the breast, but after about ten days, as the milk stopped, it was fed by another woman of the tribe. The first change of dressing was made on the third day, a needle was removed, then more followed on the fifth, and the remainder on the sixth. At every change of dressing fresh "ointment" was put on, and the secretion from the wound removed with a tampon charged with it. The dressing was always solid, and in nine days after the operation the wound was healed and the patient quite well. Beyond the interest which naturally attaches to a case of this nature, it is heightened in the present instance by the quaint native proceedings and the decidedly civilized method employed by the chief operator.

"Gall on the Liver."—During a consultation of physicians, a doctor, who, though lacking a college education, has the—to his mind—superior qualification of experience gained in fifteen years of practice, gravely stated his diagnosis to be "gall on the liver," and, judging from the amount of gas he had heard escape from the child's bowels, it was evident it also had a severe gastritis.

Cæsarean Section by an Ox.—Dr. J. Z. Scott, of Scandia, Kans., reports the following unique case: Mrs. P——, aged thirty-four, the mother of seven children, and near full term in her eighth pregnancy, on November 16th was gored by an infuriated ox. The horn of the beast entered at the anterior-superior spinous process of the ilium, and made a rent extending to the umbilicus, and involving both the abdominal parietes and the walls of the uterus. The child was extruded through the wound in half an hour after the occurrence of the accident. When Dr. Scott arrived on the scene he found the child fully delivered, but remaining attached to the cord, which he ligatured and severed. There being no dilatation of either the os uteri or the vagina, he delivered the placenta through the rent and applied a bandage. The patient was almost lifeless from hemorrhage and shock, and he placed her on morphine and whiskey. On the following day she was still alive, and Dr. Means was called in consultation at 9 30 A.M. The small intestines escaped from the wound on the removal of the bandage, and were returned with much difficulty. The wound was now closed with interrupted sutures, a carbolized compress was applied, and the morphine and whiskey continued internally. At 5 P.M. of the same day he found the pulse 130, and respiration 25 per minute. The abdomen was greatly distended, and the vital powers were fast becoming exhausted. On the following morning he found on his visit that the woman had expired at ten o'clock of the previous night. Dr. Scott believes this case to be the only authentic instance of Cæsarean section performed by a beast on record. It may be interesting to know that the child suffered little or nothing from the violent and unusual method of its delivery, and is alive to-day, a vigorous and thriving boy.—*The Medical Age*, August 10, 1885.

Teaching very Deaf Children at Home is described by an experienced teacher, Miss Warren. The deaf infant's attention is not arrested by the mother's voice as in the case of the hearing; it is thus not trained by degrees to enjoy sound. Its mind is a blank as to the "ba ba" and "da da," which early impress the unafflicted. The elements of spoken language are not found in its prattle; it is slow to associate the name with the object. A gradual improvement in the growth of speech-power in the hearing child is in proportion to the cultivation of the hearing power; the deaf child, however, is without that advantage unless direct teaching is given. Frequently a tube or trumpet is useful in arousing some latent hearing; the child gradually learns to recognize and repeat the various vowel sounds as they are spoken through it. Brightly colored pictures are shown and each object pointed out as its name is pronounced slowly, distinctly, and in a low voice near or in the pupil's ear; a loud voice will generally defeat the purpose, as its impact is so hard that it causes a shock at the expense of distinctness. The child is encouraged to repeat the word as well as it can. It may be long in remembering even one name. The lesson may be varied in many ways. Some sounds the child can learn only by placing the lips and tongue as those of the teacher are. This is the beginning of speech-reading. Variability in the hearing will often be noticed—when the child is tired, or neglecting to give attention, or when a catarrhal inflammation interferes with the equilibrium of the transmitting apparatus of the ear, upon which normal hearing depends, and which is sometimes subject to unexpected variations. Systematic instruction educates the amount of hearing that may exist, trains the eye to interpret for the ear, and awakens the young mind to the power and pleasures of speech. If hearing has been lost by illness after a child has begun to speak, it must be encouraged to use its voice until special instruction can be secured.

Longevity and Riches.—Joseph Körösi, of Buda-Pesth, in a paper read before the Association of Hygiene, in Berlin, last year, presents some figures regarding the effect of the pecuniary status of longevity. Excluding deaths in infancy, he finds, taking his observations from a period of eight years, that the rich class had a longevity of 52 years, the middle class of 46 years 1.1 month, the poor class of 41 years 7 months. In the matter of susceptibility to infectious diseases he finds that cholera, small-pox, measles, and typhoid are more prevalent among the poor, and diphtheria, croup, pertussis, and scarlet fever among the well-to-do. Zymotic diseases, as a whole, were sixty per cent. more frequent among those living in basements than in higher domiciles. But the increase in fatality in underground tenements applied only to certain diseases, as especially measles and whooping-cough, while diphtheria and scarlet fever were ten per cent. less frequent than in families living above ground.

Herpes Iris affecting the Conjunctiva.—Dr. Bergmeister describes a case of recurrent herpes iris of the conjunctiva in a stone-worker, aged thirty, who had suffered from eight attacks. The mucous membrane of the nose and mouth were free, but the skin of both arms and legs were affected with the characteristic rash. A croupous membrane was seen in the eyes; the lids were swollen, and there was much catarrhal secretion. Similar cases have been mentioned by Fuchs in 1876, and by Neumann in 1883.

HYDROBROMATE OF HYOSCINE—ITS USE IN CASES OF INSANITY.

By FREDERICK PETERSON, M.D., AND CHARLES H. LANGDON, M.D.,

ASSISTANT PHYSICIANS AT THE HUDSON RIVER STATE HOSPITAL, N. Y.

At meetings of the German Chemical Society, April 30, and July 26, 1880 (*Berichte der deutsch. chem. Gesellschaft*, vol. xiii., 909 and 1549), Professor A. Ladenburg reported some results of his researches among mydriatic alkaloids, particularly those of *Hyoseyamus niger*. At that time this plant was known to have two alkaloids, viz., crystallized and amorphous hyoscyamine. He derived a new alkaloid, hyoscine, from the latter, and it is not, as some suppose (Höhn and Reichardt), to be obtained from crystalline hyoscyamine. He finds that hyoscine, hyoscyamine, and atropia are actually isomeric, the formula for each being $C_{17}H_{23}NO_3$, and furthermore that each is separable into tropic acid, $C_9H_{10}O_3$, and tropine or pseudotropine, $C_8H_{15}NO_3$. He has also converted hyoscyamine into atropine, and atropine into hyoscyamine in his laboratory; though he has not thus far been able to transform hyoscine into either of the other mydriatics. He gave the new alkaloid to Professor Edlessen and Dr. Illing of the Kiel Policlinic for trial as to its medicinal effects. We condense the medical literature of hyoscine to the present time, as far as we know it, into the following:

Edlessen and Illing (*Centralb. für die med. Wissenschaft*, June 4, 1881) used the hydrochlorate and hydroiodate of hyoscine, preferring the latter, and giving it altogether by mouth in average doses of 1.2 milligr. They report beneficial effects in three of six cases of whooping-cough in children, six cases of asthma, two cases of enteralgia, and one of epilepsy; in the last diminishing the number of attacks. They consider it similar to atropine, but safer and more constant in its action; they also state that larger doses of hyoscine may be used without producing the constitutional symptoms common to both.

R. Gnauck, of the Charité psychiatric clinic (*Centralb. für die med. Wissenschaft*, November 5, 1881, and February 11, 1882; also *Charité Annalen*, 1882, 448), using it in both healthy and insane persons, says that it gives rise to the same physical disturbances as atropine and hyoscyamine, that like the latter it induces sleep and fatigue, but that unlike either it reduces the pulse. He further states hyoscyamine and hyoscine differ from atropine in tending to produce sleep, and that the sleep caused by hyoscine lasts but half as long as that from hyoscyamine. He employed it subcutaneously in doses of 0.0001 to 0.0025 gramme.

The above experimenters all pronounce hyoscine unusually uncertain in its effect upon different persons in the same dose, and even upon the same person at different times.

E. Emmert (*Corresp. Bl. f. schweiz. Aertzte*, 1882, No. 2) finds it much more rapid in its mydriatic action than atropine, and remarks that it should not be used in stronger than one-half per cent. solution, because of the danger of constitutional effects.

Fraentzel (*Charité Annalen*, viii., 1883, p. 301) used the hydroiodate in the night-sweats of phthisis, with marked benefit in ten cases out of twenty-nine experimented upon, in doses of one-half to one milligr.

J. A. Claussen (*Diss. Kiel*, 1883; *Centralb. f. d. med. Wiss.*, July 12, 1884) made use of the hydrobromate and hydroiodate in several cases where there was sleeplessness, without specially good, and in one with bad, results.

H. C. Wood (*Therapeutic Gazette*, January and February, 1885) has made the hydrobromate familiar to American readers by his excellent articles upon the subject. He finds hyoscine a spinal, centric respiratory and feebly cardiac depressant. The following is quoted from his first paper: "The peculiar therapeutic value which this physiological study leads us to look for in hyoscine arises from the union of decided hypnotic powers with a spinal sedative influence and a very feeble depressant action on the circulation. The experiments so far indicate also freedom from disturbance of the secretions and unpleasant after-effects."

Led by such praise, we tested the efficacy of the new and tasteless remedy in about sixty cases, some of which we here report. We sought chiefly to learn its hypnotic value. We have used some forty grains of Merck's hydrobromate of hyoscine, at seventy-seven cents per gram, both by mouth and hypodermatically. The largest dose we have given is gr. $\frac{1}{2\frac{1}{4}}$ by mouth, gr. $\frac{1}{4\frac{1}{8}}$ subcutaneously. In the appended reports of cases, the letters H. H. are an abbreviation of hydrobromate of hyoscine; doses are given in fractions of *grains;* where the method of its employment is not mentioned the doses are by mouth.

MELANCHOLIA.—CASE I.—A. A——, female, aged fifty-five; much depressed, moaning and crying aloud, delusions that her soul is lost, that she is damned, must be burned, etc., sleepless. Has slept from one to five hours nightly for the past month on two doses, each containing pot. brom., chloral, āā gr. xx. Prescribed H. H. for nearly a month, at first gr. $\frac{1}{6\frac{1}{6}}$ ter in die et $\frac{1}{4\frac{1}{2}}$ bis in nocte. The pupils were dilated on the second day, and there was also headache and dryness of the fauces and tongue. This, together with disturbance of accommodation, continued as long as the drug was used. At no time were constitutional symptoms severe. On the seventh day the dose was increased to gr. $\frac{1}{3\frac{1}{3}}$ t.i.d. On the tenth night the dose was increased to gr. $\frac{1}{6\frac{1}{0}}$ b.i.n. She had thus far slept some four to five hours nightly with these doses, but the amount of sleep seemed to diminish, and on the fifteenth night morph., gr. $\frac{1}{8}$, was added to the two night doses of H. H., gr. $\frac{1}{6\frac{1}{0}}$. From this time to the end of the month, she has slept five to six hours nightly. She is at present sleeping well on small doses of chloral and bromide. H. H. discontinued, because of disturbance to vision.

CASE II.—D. B——, female, aged twenty-eight; somewhat depressed, marked insomnia. Has usually required tr. hyos., 3 ij.; chloral, gr. x., to produce three to seven hours' sleep nightly. Prescribed H. H. for twenty nights, beginning with grain $\frac{1}{6\frac{1}{6}}$ b.i.n., increasing on the thirteenth night to gr. $\frac{1}{4\frac{1}{2}}$ b.i.n. During the latter half of the twenty nights the medicine seemed to affect her less. She slept fairly at first. A few constitutional symptoms appeared, the dilatation of pupils, disturbance of accommodation, dryness of throat, etc. On the twentieth day began to have nausea, abdominal pains and diarrhœa. The H. H., although not blamed for this, was discontinued. For a few nights she took Dover's powders b.i.n., which checked the looseness of bowels but caused no sleep. After that she slept well on chloral and bromide in small doses.

Case III.—A. H——, female, aged forty-six; great depression, sometimes excitement, sleeplessness. Has required usually tr. hyos., ʒ ij.; morph. sulph. gr. ⅜, for the past ten nights to produce three to six hours sleep. Prescribed H. H., $\frac{1}{30}$ t.i.d. et b.i.n., off and on for twenty-four days. Dilatation of pupils was the first effect. On the tenth night took gr. $\frac{1}{12}$ at 1 A.M., and was sleepless all night. Since beginning the H. H. she has slept very little. When she had sleep it came on from three-quarters to two hours after the doses were taken, and would last but two hours or so. She complains of thirst, her pupils are wide, skin cold, pulse 128, feels faint, has abdominal pains and diarrhœa. Is sent to bed and H. H. stopped. Eleventh day, pulse again normal; diarrhœa has ceased. For the remainder of the time she took gr. $\frac{1}{60}$ at night, without return of bad symptoms, but slept poorly. After the twenty-fourth day she refused to take the medicine, and has slept fairly well since without a hypnotic.

Case IV.—C. E. P——, female, aged fifty: restless, sleepless, walks up and down bemoaning her fate aloud. For a week previous was sleepless at home, and sleepless the first night of admission. Was put upon H. H., gr. $\frac{1}{30}$ b.i.n., for eight nights. The first two or three nights was sleepless, then for two nights slept four to five hours, after that sleepless and more excited. At the end of the eight days' trial was put upon tr. hyos., ʒ ij.; chloral, gr. x., b.i.n., with which she has slept from one to four hours nightly since. The constitutional symptoms from H. H. were present, but slight. When sleep seemed to be produced by it at all, from one to two hours were required before any effect was apparent.

Case V.—I. C——, female, aged twenty-four; excited, crying aloud at times, thinks she has killed her family; sleepless for some nights before admission. The first night in the hospital she slept three hours with tr. hyos., ʒ ij.; chloral, gr. x. Was put upon H. H., gr. $\frac{1}{30}$ b.i.n., for six nights, and slept four to six hours each night. A few slight constitutional symptoms were produced. Not caring to produce more, tr. hyos., ʒ j.; chloral, gr. x., one dose at night, has been prescribed since, resulting in from five to six hours' sleep nightly.

Case VI.—E. B——, female, aged fifty-three; restless, apprehensive; sleeps poorly, has præcordial fright and headache. Has slept sufficiently of late with tr. hyos., ʒ ij.; morph. sulph., gr. $\frac{1}{4}$. Prescribed H. H., gr. $\frac{1}{30}$ t.i.d., at different times through a month, and often H. H., gr. $\frac{1}{12}$; morph. sulph., gr. ⅜, at night. In two or three days she invariably became more nervous and excited, vision blurred, pupils dilated, præcordial fright greater, throat parched, and diarrhœa would set in, whereas she is naturally constipated and requires mist. aloes, ʒ j., every morning. Her bowels would move four to five times daily. As soon as the H. H. was stopped she became constipated; upon its renewal there was again laxity of the bowels. This was tried four times with the same result. The above dose of H. H. and morph. induced sufficient sleep.

Case VII.—S. N——, female, aged fifty-seven; constantly walking, talking, bewailing, picking and tearing her clothes. Up to within a few days has slept well without a hypnotic, but latterly has been out of bed and noisy the last half of each night. H. H., gr. $\frac{1}{30}$, was given for seven nights, gr. $\frac{1}{48}$ for fourteen nights subsequently. For the first few nights slept from four to five hours with this dose, but she gradually began to sleep less and to be more excitable through the rest of the time. Sleep would not come on until an hour or more had elapsed from the time of taking the dose. There was dilatation of pupils, dryness of throat, etc., from the beginning. Since abandoning the drug she has slept well without medicine.

Case VIII.—J. D——, male, aged twenty-two; confused, depressed, delusion that he is in every way ruined; paces restlessly to and fro during day. Has been for some weeks sleeping well at night. Prescribed H. H., gr. $\frac{1}{30}$ t.i.d. five days, gr. $\frac{1}{60}$ for six days, and gr. $\frac{1}{12}$ for fourteen days—twenty-five days in all. On the fourth day pupils were dilated, pulse feeble, and extremities cold. On the twelfth day pulse was 100 and irregular. No change in his restlessness or mental condition. On the twentieth day was much more agitated, wringing his hands, etc. At 8.45 P.M. pulse was 82; H. H., gr. $\frac{1}{30}$, was given hypodermatically. Nine o'clock, pulse 78, pupils much dilated. Says he feels "faint;" went to bed at 9.45 P.M., and slept the greater part of the night. The next day he was depressed as usual, lamenting, walking restlessly to and fro, pupils very widely dilated, mouth and throat dry. On the twenty-fifth day he was very much agitated and disturbed, and H. H. was discontinued and Brown-Séquard's mixture of the bromides substituted. On the thirtieth day he was much quieter, though depressed as before. His appetite, which became impaired while on H. H., has also improved.

Case IX.—C. C. J——, male, aged thirty-five; quiet, confused, depressed, has auditory hallucinations, and under their influence is at times violent. For several nights has taken potassii bromidi and morph. sulph. Prescribed H. H., gr. $\frac{1}{30}$ twice nightly for four nights, when the dose was increased to gr. $\frac{1}{12}$ b.i.n., and H. H., gr. $\frac{1}{30}$, was ordered t.i.d. With the exception of two hours during the first night, two hours during the fourth night, patient has had no sleep since he commenced taking H. H., his appetite has failed and he has become more confused. On the sixth day, after passing a sleepless night, his pupils were very widely dilated; pulse 42, small and almost thready; extremities cold; muscular tremor present, mouth parched; he was utterly dazed and bewildered. H. H. was discontinued and stimulants ordered. The next day his pulse was 78 and stronger. On the ninth day he was ordered H. H., gr. $\frac{1}{12}$; morph. sulph., gr. $\frac{1}{4}$; sp. frumenti, ʒ j., b.i.n. for fourteen days. For the first two nights this combination seemed to produce from five to seven hours' sleep, but after that the amount of sleep obtained steadily decreased. On the twenty-third day night medicine was changed to morph. sulph., gr. $\frac{1}{4}$; tr. hyos., ʒ ij., b.i.n. While taking H. H. at night pulse would usually fall to 50, appetite became impaired, and there was no improvement in his mental condition.

Case X.—M. B——, male, aged twenty-nine; noisy, garrulous, restless, unhappy. Sleeps well usually at night. Prescribed H. H., gr. $\frac{1}{30}$ ter in die. On the fourth day is much quieter; pupils dilated; throat dry. On the sixth day the dose of H. H. was increased to gr. $\frac{1}{12}$. On the eleventh day pulse was 78 and feeble, circulation poor. Appetite has been poor for past week, and for two days past has complained of nausea and pain in abdomen. Complains of shortness of breath; says he "can scarcely get his breath." Refusing to take his medicine it was discontinued. Continued quiet for two days and then became noisy and garrulous as before, when it was again prescribed, producing similar train of symptoms, viz., dilatation of the pupils, dryness of fauces and throat, anorexia, but marked diminution of his garrulity.

Case XI.—T. M.——, male, aged thirty; quiet, confused, sullen, suspicious, depressed. Is troubled with insomnia, but obtains three to six hours of sleep after taking chloral and tr. hyos., or morphine. Prescribed H. H., gr. $\frac{1}{30}$ b.i.n. Did not sleep any during the first two nights. On the third day there was increased excitement; he was noisy at times and destructive; pupils are dilated; throat is dry; says that he thinks one of the attendants jumped down his throat and is stuck there. H. H., gr. $\frac{1}{12}$, ordered b.i.n. for four nights. Slept for three hours the first of these nights, but did not sleep during any of the other three. H. H., gr. $\frac{1}{60}$ b.i.n., ordered for one night; pulse varied from 56 to 60 during the night; did not sleep. H. H., gr. $\frac{1}{48}$ b.i.n., ordered for ten nights. During this time but two hours of sleep a night were obtained; constitutional symptoms were

marked; pupils dilated, throat dry, there was considerable irritation of the skin, and an apparent sensation of heat; patient scratches himself much; much muscular tremor present. The next night two doses of H. H., gr. $\frac{1}{30}$, were now given, producing only two hours of sleep. The following night no H. H. was given, but took chloral, gr. xx., in whiskey punch; slept only one hour, and was noisy afterward. H. H., gr. $\frac{1}{15}$; morph. sulph., gr. $\frac{1}{4}$; sp. frumenti, ʒ j., was now ordered b.i.n. for three nights. The first of these nights he obtained two hours of sleep and was quiet. The following day he was greatly disturbed, was violent and treacherous and destructive. At noon his pulse was 88; H. H., gr. $\frac{1}{48}$, administered hypodermatically. Ten minutes after injection pulse was 96; ten minutes later pulse was 114. Five minutes later he became delirious, very noisy, incoherent, weeping and sobbing. This excitement continued for twenty minutes and then subsided, and he became very quiet and remained so for some hours, but did not sleep, and did not sleep during the succeeding night and the night after that. Is dazed, bewildered, tremulous, excitable, pupils dilated, staggers in walking; pulse feeble and rapid; looks haggard and general appearance is bad; scratches himself; tears off his clothing. Ordered H. H. to be discontinued. Prescribed Brown-Séquard's mixture during the day and chloral and tr. hyos. at night. The first night of the change he slept for six hours, and since then to the time of present writing, six days, he slept the greater portion of each night. Constitutional effects of H. H. have disappeared; appetite has improved; is not noisy or destructive.

Case XII.—B. S. K——, male, aged thirty; confused, depressed, excited. Has increased motility, walks much; has marked auditory and ocular hallucinations; thinks he is being persecuted by enemies and spirits. Pulse full, and at times rapid. Sleep irregular. Usually takes morph. sulph. and Brown-Séquard's mixture at night, and sleeps from six to seven hours, though occasionally will not sleep any, and occasionally will sleep all night without medicine. Is taking Brown-Séquard's mixture, ʒ j. t.i.d. Prescribed H. H., gr. $\frac{1}{60}$ ad nocte. Slept well the first night. The second night was restless and slept only two hours. Slept four hours the third night, and on the following day was very much disturbed, noisy, and violent; hallucinations of hearing prominent. On the fourth night slept but two hours, and was much excited after two o'clock. Noisy, shouting "Murder!" "Fire!" Was given a dose of potass. brom., ʒ ss.; morph. sulph., gr. $\frac{1}{4}$, and soon became quieter. Fifth, sixth, seventh, and eighth nights slept without medicine. Ninth, tenth, and eleventh nights took H. H., gr. $\frac{1}{30}$, at 10 P.M., and slept afterward. Pupils are now dilated, throat dry. Hallucinations much less marked; is quiet; says he is feeling better. Twelfth day was wakeful much of the night. H. H., gr. $\frac{1}{30}$, ordered b.i.n. Thirteenth day took doses at ten o'clock and at one o'clock; slept one hour after the first and two hours after the second dose. Fourteenth day slept half the night without medicine. From the fifteenth to the twenty-third night, with the exception of the sixteenth, when he slept three hours, he obtained seven to eight hours' sleep each night after taking one dose of H. H. Is now becoming more disturbed during day, and hallucinations of hearing are again troublesome, pupils are dilated and throat dry, pulse is normal. Brown-Séquard's mixture is discontinued, and H. H., gr. $\frac{1}{30}$, ordered t.i.d. Twenty-fourth day slept most of the night after taking H. H., gr. $\frac{1}{60}$, at ten o'clock. Thirty-fourth day: Has continued to take H. H., gr. $\frac{1}{30}$, t.i.d. et gr. $\frac{1}{60}$ ad nocte. Has been quiet during the day; is less confused and depressed; not so restless. With the exception of the twenty sixth night, when he was restless, the greater part of the time he has slept well for the past ten nights. Pupils are dilated and throat is dry. Of late there has been anorexia and medicine is discontinued.

Remarks.—We have tried H. H. in these cases more particularly to test its hypnotic effect and power to allay excitement, not so much with a view to ameliorate the psychic symptoms of melancholia, and find that it has no particular value for either.

Acute Mania.—Case XIII.—A. G——, male, aged forty; noisy, incoherent, destructive, and violent. Has hitherto slept well on one dose nightly of tr. hyos., ʒ ij.; chloral, gr. xv. Is put upon H. H., gr. $\frac{1}{60}$ t.i.d. et ad nocte. Sixth day: Has slept well thus far, but last night only three hours. Is more excited, jumping wildly about and shouting; pupils wide, extremities cold, face flushed, mouth dry. Eighth day: Quieter. Tenth day: Sleeps two to three hours now; pulse during night 56. Night dose of H. H. increased to gr. $\frac{1}{15}$ b.i.n. Eighteenth day: Sleeps two to three hours only; very excitable to-day, noisy and destructive; noisy at night when not asleep; pulse varies nightly from 78 to 64. At 2.50 P.M. to-day extremely boisterous; pulse 90. Is given H. H., gr. $\frac{1}{60}$, hypodermatically. 2.55 P.M., pulse 86. 2.57 P.M., pulse 92. 3 P.M., pulse 80. 3.15 P.M., pulse 80. Fought desperately against a second hypodermatic with a chair; said he felt drugged. Became very violent and furious, wrenching a strong chair from the floor and breaking it. This excitement was of short duration. 3.50 P.M., quiet and lying down. 4.05 P.M., pulse 120; again very noisy and excited. 4.45 P.M., took gr. $\frac{1}{60}$ by mouth; pulse 80; is quiet. 5 P.M., pulse 70; very quiet, face flushed, voice hoarse. 9 P.M., has slept until now; awake and quiet; pulse 62. Twenty-first day: Has slept two to three hours nightly since last note on usual doses; pulse varies nightly from 88 to 64, and is often variable by day. To-day is very much disturbed and violent; tears off his clothing, and seems to have an unnatural sensation of heat of skin. Pupils widely dilated and face flushed. Twenty-fourth day: Continues noisy and destructive of clothing; sleeps but two to three hours at night with usual doses; pulse varies nightly from 80 to 60. Night doses now increased to $\frac{1}{60}$. Twenty-fifth day: Slept but three hours last night. Night doses increased to gr. $\frac{1}{30}$. Twenty-seventh day: Slept but three hours the last two nights; more excited to-day; pupils widely dilated; scratches chest, back, and arms, and tears off clothing. The H. H. is now discontinued altogether. Thirty-fifth day: Has slept well every night since last note on tr. hyos. and chloral, and has grown quieter on Brown-Séquard's mixt. t.i.d. Now keeps his clothing on.

Case XIV.—H. A. B——, male, aged twenty-seven; noisy, incoherent, violent, excitable, and destructive by day. Has been sleeping well for the past ten nights on tr. hyos., ʒ ij.; chloral, gr. x., one dose nightly. Prescribed H. H., gr. $\frac{1}{120}$ t.i.d. et ad nocte. Fifth day: Has thus far slept as well as usual, but by day has been unusually disturbed; pupils slightly dilated, face flushed. Day doses increased to gr. $\frac{1}{60}$ t.i.d. Eleventh day: Does not sleep as well; quieter and confused by day; pupils quite dilated, throat and mouth dry, extremities cold, pulse 78 to 70. Night doses also increased to gr. $\frac{1}{60}$ b.i.n. Nineteenth day: Pulse has varied nightly since last note from 106 to 60. Has slept quite well, but is noisier by day; this afternoon and evening unusually excited. 8.30 P.M., is given H. H., gr. $\frac{1}{60}$, hypodermatically; pulse 96. 8.55 P.M., pulse 120, pupils widely dilated, face flushed. 9.40 P.M., hypodermatic of gr. $\frac{1}{60}$ repeated; pulse 104. 10 P.M., very noisy, raving, delirious; could not get at pulse to feel it. In a few minutes became quiet and went to sleep. Slept lightly one hour. Twentieth day: 1 A.M., took $\frac{1}{60}$ by mouth and slept three hours. Quieter to-day; pulse 102 and feeble; pupils greatly dilated. Twenty-second day: Night doses increased to gr. $\frac{1}{30}$ b.i.n. Twenty-fourth day: Sleeps but about three hours nightly with the two doses; pulse very variable, 56 to 102; is much more disturbed and noisy by day; seems also more erotic; masturbates much. Twenty fifth day: Slept but one hour on the two doses. Pulse feeble and rapid, eyes suffused, pupils large, muscular tremor marked, seems utterly dazed, wild and haggard, is delirious. The H. H. is now discon-

tinued and patient put upon Brown-Séquard's mixture t.i.d., and two doses nightly of tr. hyos. and chloral. Thirty-fifth day: Has been sleeping two to four hours nightly since last note. Patient is quieter and his appetite, which had become much impaired under H. H. treatment, is restored.

CASE XV.—S. H. B——, female, aged forty; noisy, incoherent, destructive, filthy. For the past ten nights has slept two to three hours with tr. hyos., 3 ij.; chloral, gr. v., one dose nightly. Very noisy when awake. Put on H. H., gr. $\frac{1}{6}$, at night. Ninth day: Has been sleeping two to five hours on H. H.; dose now increased to gr. $\frac{1}{4}$. Nineteenth day: Has been sleeping four to five hours every night; noisy when awake. Dose now increased to gr. $\frac{1}{3}$, which she took two or three nights, sleeping well. Since then (for three weeks) to present writing has been sleeping well all night without medicine; is quieter by day. The constitutional symptoms in her were very slight. It always required from half an hour to one hour for the H. H. to take effect.

CASE XVI.—J. A——, female, aged twenty-three; very noisy, incoherent, in constant motion; is exhausting. Is an idiot with acute mania. Is reported to have been sleepless for several nights previous to admission. First night in hospital was noisy all night; was then put on H. H., gr. $\frac{1}{6}$. Tenth day: Has slept from three to five hours every night with this dose; dose now increased to gr. $\frac{1}{2}$. Is growing stronger bodily; sitting up; pupils dilated and face flushed some days. For nine nights following was given this dose; sleeping well at first, but gradually sleeping less. Nineteenth: Dose increased to gr. $\frac{1}{6}$. Was sleepless for two nights, but, after that, slept so well for a week with this dose and improved so much, that it could be discontinued. She now sleeps without medicine.

CASE XVII.—M. E. R——, female, aged sixty. This case is the most instructive, and we report it in full. Her mania is but of few days' duration. Admitted August 19th. She has refused food and medicine, does so now, and permits no physical examination. Is extremely obscene, profane, violent, and destructive. Seems to be exhausting, and prognosis of death in a few hours is made. Is put in a camisole in bed. At 3.55 P.M., H. H., gr. $\frac{1}{6}$, is forcibly injected into her leg; 4.25, still furiously maniacal. A second gr. $\frac{1}{6}$ is now injected; 4.30, is quieter, but too resistant to take pulse. Pupils dilated; 4.35, pulse 88. Still tries to be noisy, but cannot articulate; to resist, but lacks the power. 4.40, pulse 88, respiration 16; is sleeping quietly. 7 P.M., awoke stupid and weak; 7.30, took a milk-punch. At 9 awake, but quiet. 10.30, took half a milk-punch, which contained H. H., gr. $\frac{1}{6}$, and also three-quarters of a glassful of milk. Was sleepless and noisy at times the rest of the night.

August 20th.—Very noisy most of the forenoon; will not allow pulse to be felt. 11.55 A.M., H. H., gr. $\frac{1}{2}$, forcibly injected hypodermatically. 12.10 P.M., got out of bed; staggered like a drunken person; talked thickly; voice hoarse; less noisy, but impossible to get at pulse; drank a little milk. 12.15 o'clock: perfectly quiet in bed; drowsy; took a pint of milk. 12.20 o'clock, is dozing; pulse 96. 2.25 o'clock, P.M., awoke and took nourishment; is quiet and stupid. 2.40 o'clock, went to sleep again. 9 o'clock, P.M., has been stupid and quiet all the afternoon and evening; has taken milk and beef extract. 10.30 o'clock, P.M., took a milk punch containing H. H., gr. $\frac{1}{6}$. Sleepless all night, and noisy after 3 o'clock; took milk at intervals.

August 21st.—5.35 P.M.: Has slept about three hours during the day, but has been extremely noisy the entire afternoon; impossible to induce her to take a single swallow of food or drink; H. H., gr. $\frac{1}{3}$, injected hypodermatically forcibly. 5.50 o'clock, quiet; beginning to doze; refuses nourishment. 6 o'clock, asleep; continued to sleep until 12.20 A.M. 1 A.M., took punch containing H. H., gr. $\frac{1}{6}$, and nourishment at different times afterward; slept no more; very noisy between 1 o'clock and 3 o'clock.

August 22d.—8 A.M.: Went to sleep after taking a pint of farina and milk. 11 o'clock, A.M., is awake and quiet, except when people enter her room, when she becomes furious. 5 o'clock, P.M., H. H., gr. $\frac{1}{2}$, injected hypodermatically. Has been extremely noisy all the afternoon. 5.15 o'clock, quiet, but not asleep. Took three eggs, a glass of milk, and 3 ij. meat extract, then went to sleep. 5.40 o'clock, sound asleep.

August 23d.—12.20 P.M.: Slept last night until 2.30 o'clock this morning. Very noisy after that until now, but took a punch containing H. H., gr. $\frac{1}{6}$, which had no effect; H. H., gr. $\frac{1}{6}$ injected hypodermatically. 1.10 o'clock P.M., stupid, but still awake; quiet; takes liberally raw eggs, milk, whiskey, and meat extract (one pint altogether). 1.25 o'clock, P.M., sound asleep. 2.25 o'clock, P.M., awake and noisy as ever. 5.20 o'clock, P.M., continues to be noisy, is furious whenever any one enters her room; a second hypodermatic injection of H. H., gr. $\frac{1}{6}$, is given. 5.35 o'clock, went to sleep. 7 o'clock, P.M., woke up; is well fed; went to sleep again.

August 24th.—Continued to sleep until 10.40 o'clock, P.M., last night; very noisy after that time. 12 o'clock, noon, has been as violent, profane, and obscene as possible, up to this hour; H. H., gr. $\frac{1}{4}$, is now given hypodermatically. 12.10 o'clock, P.M., asleep; is easily roused, and takes a quantity of food; pulse 80, tongue and lips covered with sordes. 4 o'clock, P.M., awoke and is fed. 5.40 o'clock, P.M., noisy for the last hour. H. H., gr. $\frac{1}{4}$, injected hypodermatically; went to sleep in a few minutes; slept for three hours, when she awoke and became exceedingly noisy; refused nourishment.

August 25th.—11.30 A.M.: Has been exceedingly noisy until this time; H. H., gr. $\frac{1}{4}$, injected hypodermatically, became quieter at 12 o'clock; took some nourishment but vomited part of it. 5.30 P.M., very noisy; second hypodermatic of H. H., $\frac{1}{4}$ gr., given. 6.10 P.M., has taken considerable nourishment to-day, is now asleep. 9 P.M., is still asleep.

August 26th.—Did not sleep after 10.30 P.M., noisy all night; took some milk but did not retain it, vomited several times; very quiet this morning; has taken nourishment voluntarily. 5 P.M., quite noisy this afternoon, H. H., gr. $\frac{1}{4}$, given hypodermatically; took a pint of liquid nourishment and went to sleep shortly after 6 o'clock. 9 P.M., still sleeping.

August 27th.—Slept until 12.45 o'clock this A.M., sleepless afterward; drank three glasses of milk without compulsion; vomited a little at 6 A.M.; quiet this morning and somewhat rational, but toward noon became noisy, when she was given H. H., gr. $\frac{1}{6}$, hypodermatically; slept about four hours. 7.30 P.M., a second hypodermatic injection of H. H., gr. $\frac{1}{6}$, given, went to sleep in fifteen minutes; has had some diarrhœa to-day. 9 P.M., sleeping.

August 28th.—Slept until 12.15 o'clock this morning, and again from 1 o'clock until 4.30 A.M.; took a fair amount of nourishment this forenoon; bowels loose. 11.30 A.M., very noisy; H. H., gr. $\frac{1}{6}$, given hypodermatically; slept about three hours. 5.30 P.M., second hypodermatic solution H. H., gr. $\frac{1}{6}$, given. Went to sleep at 6.30 P.M., and slept the greater portion of the night.

September 5th.—Has not been given any medicine since; has slept fairly well every night, and takes plenty of nourishment; is up and dressed, and goes out of doors; is quiet and pleasant, talks rationally of home and home-affairs; is neither profane nor obscene, and appears to be rapidly convalescing; the diarrhœa and vomiting ceased with the hypodermatics.

CASE XVIII.—P. H——, female, aged twenty-eight; noisy, violent, filthy, destructive, erotic, obscene, puerperal. Was sleepless and noisy nearly every night for a week preceding the prescription of H. H. Was given H. H., gr. $\frac{1}{6}$, for three nights without effect; the dose was increased to gr. $\frac{1}{2}$ for six nights; became more

noisy, and with the exception of two hours occasionally, was sleepless each night. The dose was increased to gr. $\frac{1}{4}$ for ten nights, but was as noisy and sleepless as before. The constitutional symptoms were now quite marked: pupils were dilated, face flushed, there was anorexia and diarrhœa. Was now put on two doses nightly of pulv. Dover, gr. x., for six nights, the H. H. being altogether discontinued. This checked the diarrhœa, and she slept well each night. Since then has slept fairly without any medicine.

Case XIX.—E. M. B——, female, aged twenty-two; noisy, destructive, violent, garrulous, incoherent, puerperal. First night after admission was sleepless and noisy all night. Was given H. H., gr. $\frac{1}{60}$, for the three following nights, inducing each night from four to five hours' sleep; dose increased to gr. $\frac{1}{12}$ for nine succeeding nights, during which she slept a little better than before. For five nights following this she took gr. $\frac{1}{60}$, but slept only two to three hours nightly, and is more noisy day and night than usual; pupils dilated; face flushed. The H. H. is discontinued, and for the past two weeks has been sleeping four to six hours nightly on tr. hyos., ʒ ij.; chloral, gr. x.

Case XX.—E. J. E——, female, aged twenty-six; sleepless, violent, noisy, destructive, profane, obscene, erotic, puerperal. Has usually slept sufficiently on tr. hyos., ʒ ij.; chloral, gr. x. Has taken thus far Brown-Séquard's mixt., ʒ j. t.i.d. All this is discontinued and patient is put upon H. H., gr. $\frac{1}{30}$ t.i.d., et ad nocte. For five nights she slept five to six hours nightly on one dose; became much more excited and noisy by day; pupils greatly dilated, face flushed and hot, voice hoarse; pulse rapid and weak. Day doses of H. H. discontinued. H. H., gr. $\frac{1}{12}$, given for nine succeeding nights, and gr. $\frac{1}{60}$ for five nights after, causing some four to five hours sleep nightly, but is more noisy, destructive, excitable, and violent than before taking the remedy. H. H. is discontinued; has refused other hypnotics since, but sleeps four to five hours nightly as before. It is now ten days since H. H. was given. Under Brown-Séquard's mixt., ʒ j. t.i.d., much of her excitement has abated in this time.

Case XXI.—B. J. B——, male, aged twenty-two; maniacal excitement in the course of imbecility; very noisy by day; has slept fairly of late with tr. hyos., ʒ ij. Took for six days H. H., gr. $\frac{1}{120}$ t.i.d. et ad nocte, without special change, when day doses were increased to gr. $\frac{1}{60}$ t.i.d. Tenth day: Has slept but little for several days; pupils much dilated, skin cold, pulse slow, but would not allow it to be counted, face flushed; unusually noisy and destructive to day; whistling and laughing much. Night doses of H. H. were gradually increased now until the fourteenth day, when he took gr. $\frac{1}{30}$, but his sleep became less. At night his pulse would vary from 100 to 64. Twenty-second day: Has taken gr. $\frac{1}{12}$ twice nightly since the fifteenth, generally sleeping but three hours. Is quieter now by day, but confused, and undresses himself, seeming to suffer from sensations of heat of skin. Got into the sink and started the cold water running over him. Pupils largely dilated, conjunctiva injected, and face flushed. Seems to have constant erections of penis which he had not had before. Twenty-seventh day: This symptom having become much aggravated, and his sleep growing less, the H. H. is now discontinued altogether. Had began to tear his clothes off. Is prescribed now tr. hyos., ʒ ij.; chloral, gr. x., with which he has slept four to five hours nightly for some time. Is again quieter by day.

Recurrent Mania.—Case XXII.—J. S——, male, aged forty-seven. His period of excitement has just commenced. Ordered H. H., gr. $\frac{1}{15}$ t.i.d. On the first day and night was very noisy, incoherent, violent, and treacherous. Second day: Slept all night. Pupils dilated, pulse 70, fauces dry; very much quieter. Fourteenth (time of present writing): Has slept well every night. Has had no further return of excitement. His attacks have always heretofore lasted three to four weeks in spite of all treatment employed.

Chronic Mania.—Case XXIII.—A. B——, male, aged fifty-three; destructive, violent, filthy, at times somewhat noisy. For several nights prior to taking H. H. had slept fairly well after taking chloral, gr. xv.; tr. hyos., ʒ ij. Prescribed H. H., gr. $\frac{1}{60}$ ad nocte, for twenty-nine nights. During this period he usually slept from three to six hours at night. There was some increase in his excitement by day, but no marked constitutional symptoms were noticeable except dryness of throat and dilatation of the pupils.

Case XXIV.—C. J——, female, aged forty-nine; filthy, obscene, profane, mischievous, violent, and treacherous. Is often sleepless and noisy at night. Prescribed H. H., gr. $\frac{1}{60}$ ad nocte, for five nights, on the sixth night the dose was increased to gr. $\frac{1}{30}$. Took this almost nightly for a month and usually obtained from six to eight hours of sleep. Would sleep some nights without medicine. With the exception of dilatation of the pupils, at no time has she exhibited any constitutional effects.

Case XXV.—H. N——, female, aged sixty-five; nervous, excitable, and sleepless. For ten nights previous to taking H. H. was sleepless each night, though she took chloral, gr. v.; tr. hyos., ʒ j. Took H.H., gr. $\frac{1}{60}$, for eight nights, producing from four to six hours of sleep each night. Dose was now increased to gr. $\frac{1}{30}$, upon which she usually slept about six hours. On the eighteenth day the dose was increased to gr. $\frac{1}{60}$. Pupils were now dilated, tongue and fauces dry, face flushed, but pulse normal. Not sleeping well, morph. sulph., gr. $\frac{1}{4}$, was added to H. H., gr. $\frac{1}{60}$, for the first three or four nights; slept about four hours on this. After that time till the present (eighteen days) has slept from six to eight hours each night on same.

Case XXVI.—L. V. S——, female, aged seventy-five; filthy, violent, and noisy. Previous to being put on H. H. she usually obtained from three to six hours' sleep every other night on various hypnotics. H. H., gr. $\frac{1}{60}$, was taken for eight nights, causing an average of six hours of sleep nightly. The dose of H. H. was now increased to gr. $\frac{1}{30}$, which she took for eleven nights. At first slept well on this, but the amount of sleep being afterward reduced to three hours, H. H., gr. $\frac{1}{15}$, was prescribed. Pupils have been dilated for several days, throat is dry; complains that she is losing her voice and says that somebody has been giving her ratsbane. The first dose of H. H., gr. $\frac{1}{15}$, caused her to sleep all night, but the amount of sleep obtained being again reduced to three hours, H. H., gr. $\frac{1}{30}$, was ordered on the twenty-sixth night, which she took for five nights, obtaining an average of five hours of sleep nightly. The amount of sleep now again diminishing, H. H. was discontinued and chloral, gr. x.; tr. hyos., ʒ ij., substituted, which, to the present writing (ten days), has produced nightly from four to six hours of sleep.

Case XXVII.—E. J. D——, female, aged fifty-one; exceedingly noisy, violent, filthy, and destructive; is excited night and day; is in almost constant motion, stamping and gesticulating. For ten days previous to taking H. H. took nightly chloral, gr. x., tr. hyos., ʒ ij., which produced occasionally one or two hours of sleep. H. H., gr. $\frac{1}{60}$, was now prescribed b.i.n. for nine days. The first night she slept but two hours. The succeeding two nights she averaged six hours of sleep. The fifth night she slept only two hours; the sixth night not any. On the tenth night H. H., gr. $\frac{1}{30}$ b.i.n., was ordered. On the fourteenth the dose of H. H. was increased to gr. $\frac{1}{60}$. On the seventeenth to gr. $\frac{1}{15}$. On the twenty-fourth to gr. $\frac{1}{30}$, and on the thirty-first to gr. $\frac{1}{24}$. Following each increase in the dose of H. H. (b.i.n.), for a night or two there would be a slightly increased amount of sleep, but after two or three nights she would be so tolerant of the increased doses that they would have no hypnotic effect. Constitutional symptoms appeared about the tenth day, and from that time till the

medicine was discontinued her pupils were dilated, her skin dry and hot; her excitement seemed to be increased by the H. H. On the twenty-sixth day two doses of H. H., gr. $\frac{1}{60}$, were administered hypodermatically, twenty minutes apart. Pulse at time of first injection was 86; twenty-five minutes after the second it was 112, and she was quiet and drowsy. Ten minutes later pulse was 104, and she was asleep; ten minutes later pulse was 94, and respirations were 18; was still asleep; slept for about two hours. As she was deriving no benefit from H. H., its use was discontinued on the thirty-third day, and chloral, gr. x.; potass. bromide, gr. xv., substituted. Has derived sufficient sleep from this dose for several nights past.

Dementia.—Case XXVIII.—O. M. L——, male, aged sixty-six; quiet, pupils contracted, pain and fulness in the head, marked paralysis agitans, senile dementia. Ordered H. H., gr. $\frac{1}{60}$ t.i.d. Third day: Says the pains in his head are gone. They had been there for a year. Seventh day: Pupils dilated; says he feels better. The paralysis agitans is less marked than for many months.

Case XXIX.—A. M——, male, aged sixty-nine; senile dementia. Talks through imaginary telephones in loud voice; very noisy by day, but sleeps fairly at night. Put on H. H., gr. $\frac{1}{60}$ t.i.d. Fourth day: Pupils dilated; sleepless and noisy for two nights. Began to have diarrhœa to-day: the latter growing worse, the H. H. was discontinued the next day, after which it ceased. Seventh day: Put on H. H., gr. $\frac{1}{72}$ t.i.d., as he is quite turbulent and boisterous, and also the same dose at night. The medicine is put in his food, because refused. Tenth day: Is sleeping well; is quieter by day; pupils dilated; throat dry; some anorexia. H. H. was discontinued a few days afterward because of failing appetite.

Case XXX.—J. P——, female, aged twenty-five; noisy and sleepless at night for the past week. Tr. hyos., ℥ ij.; chloral, gr. v., has had little effect. Took H. H., gr. $\frac{1}{72}$, for eight nights, sleeping the first few nights between three and four hours, but longer afterward. The following six nights slept well all night with gr. $\frac{1}{60}$. Generally sleep would come on in from one to two hours after taking the dose. On the fourteenth day the H. H. was discontinued. Thus far had moderate dilatation of pupils, some thirst, and had developed a tendency to tear off her clothes and be nude. Patient was too demented to say whether the skin was irritated or not. Twenty-fourth day, has been sleeping well on tr. hyos., ℥ ij.; chloral, gr. x. Does not tear clothes as she did.

Case XXXI.—M. A. J——, female, aged twenty-two; exceedingly filthy, destructive, violent, obscene, and noisy. For ten nights previous to taking H. H. was noisy much of the night, or all night at times. Was given H. H. for two weeks, beginning with gr. $\frac{1}{60}$ and increasing to gr. $\frac{1}{48}$, and slept on an average five hours nightly. Moderate dilatation of the pupils was produced, but no other constitutional symptoms.

Case XXXII.—E. H——, female, aged forty-seven; quiet, idle, and stupid by day; sleepless and out of bed all night. For the past ten nights has taken tr. hyos., ℥ ij., without effect. Was now put on H. H., gr. $\frac{1}{60}$, for twelve nights, sleeping the first ten of these nights very well all night, but the last two nights wakeful as usual. The dose was now increased to gr. $\frac{1}{72}$ for six nights, with which she slept from two to five hours nightly. Nineteenth day: Dose increased to gr. $\frac{1}{48}$, with which she slept five to six hours nightly for the following ten nights. On the twenty-first day of her taking H. H. complained of the increasing constitutional symptoms. Pupils widely dilated; pulse, 60; throat and mouth dry; dozes in the day-time; bowels relaxed and move three to four times daily. Thirty-second day: The last few nights she slept but two hours nightly on gr. $\frac{1}{48}$. The looseness of bowels continues; gait unsteady; anorexia, and other constitutional effects marked. Is evidently sleeping less with increase of dose and long continuance of the drug. Forty-fifth day: Since the last note has slept from four to seven hours nightly on pot. brom., gr. xv.; chloral, gr. x. This case illustrated particularly well the long time required for the remedy to take effect in some cases when given by the mouth. She invariably took the dose at 10 P.M., and as invariably went to sleep at 11.30 or 12 P.M., thus requiring one and a half to two hours to cause sleep.

General Paresis.—Case XXXIII.—F. H——, male, aged twenty-two; very restless, excited, *délires des grandeurs*, noisy, destructive. Has usually slept well after taking chloral, gr. xx.; tr. hyos., ℥ ij. Prescribed H. H., gr. $\frac{1}{72}$ t.i.d. et ad nocte. For three nights slept well, but continued to be excited and noisy by day; pupils are dilated, face is slightly flushed. On the fourth the night dose was increased to gr. $\frac{1}{60}$, and on the seventh the day doses increased to gr. $\frac{1}{60}$; on the eleventh day the day doses were increased to gr. $\frac{1}{72}$. Has been extremely noisy of late during the day. On the thirteenth gr. $\frac{1}{72}$ ordered b.i.n. On the nineteenth was very wild, noisy, and excitable; H. H., gr. $\frac{1}{60}$, was given hypodermatically at 2.55 P.M.; at 3 P.M. pulse was 96; at 3.05 P.M., 100; at 3.10 P.M., 100; pupils very wide; 3.20 P.M., pulse 100; 3.25, a second hypodermatic injection of gr. $\frac{1}{60}$ was given; pulse, 102; 3.30 P.M., 104; 3.35 P.M., 124, leaping suddenly twenty beats; now commenced feeling "faint and sick;" face flushed; eyes suffused; pupils very large; noisy, garrulous, excited; 3.40, pulse 110. Says he wants a drink; lips, tongue, and throat parched and dry; says he feels "as weak as a cat." 3.45 P.M., pulse, 116. Commenced destroying his bed. 4.05 P.M., pulse, 104; is not asleep, but is quiet, sitting up. 4.45 P.M., took gr. $\frac{1}{72}$ by mouth; 5 P.M., pupils very greatly dilated; articulation difficult; is hoarse; pulse, 96. 9 P.M., is sleeping, but readily roused; pulse, 69. Was awake at 10 P.M.; pulse, 88. Took gr. $\frac{1}{72}$, and slept for about an hour. At 1 A.M. took another gr. $\frac{1}{72}$, and slept two hours. Pulse varied during the night from 88 to 80. The next day was very noisy and excited. The following night the hypodermatic injections and night doses were repeated, producing not more than one hour of sleep. Twenty-fifth day: Doses at night increased to gr. $\frac{1}{60}$. For several days has denuded himself, and has had apparently a sensation of heat and irritation of the skin; scratches chest and limbs much. Twenty-seventh day: H. H. was discontinued altogether. Patient's excitement has been increased by it. Is now delirious, maniacal, and almost uncontrollable. Brown-Séquard's mixture ordered during the day, and chloral and tr. hyos. at night. For the past five nights, to present, writing, has slept all night, and is quieter by day.

Case XXXIV.—C. P——, male, aged forty-six; excited, restless, *délires des grandeurs*. Sleeping well on chloral, gr. x.; tr. hyos., ℥ ij. Ordered H. H., gr. $\frac{1}{60}$, b.i.n., for sixteen nights. Did not sleep any the first night. Had nausea and vomiting the latter part of the second night. Second to fifteenth nights inclusive, slept from three to five hours. Sixteenth, slept but one hour after the second dose. H. H. now discontinued, and chloral, gr. xv.; tr. hyos., ℥ ij., ordered. Pupils slightly dilated, but no other constitutional effects of H. H.

Case XXXV.—H. G. P——, male, aged forty; in stage of maniacal excitement. Has slept from three to five hours on chloral, gr. x.; morph. sulph., gr. $\frac{1}{4}$. Prescribed H. H., gr. $\frac{1}{60}$ b.i.n., for five nights and gr. $\frac{1}{72}$ b.i.n., for four nights. Obtained nightly from two to four hours of sleep. During the last three days had attacks of vomiting, and a diarrhœa, to which he is subject, coming on, the H. H. was discontinued and former hypnotic returned to. No apparent constitutional effects except dilatation of the pupils.

Case XXXVI.—J. F. E——, male, aged forty-three; delusions of exaltation; some restlessness. Has, as a rule, slept from five to seven hours at night after taking chloral, gr. v.; tr. hyos., ℥ ij. Prescribed H. H., gr. $\frac{1}{60}$ ad nocte, for twenty nights. Slept about the same number

of hours each night as he had been accustomed to after taking chloral and hyos. Pupils have been dilated; pulse has varied at night from 80 to 64. No other constitutional symptoms have been exhibited.

Epilepsy.—We have also given H. H. to twelve epileptics, six females and six males, whose seizures mostly occurred from daily to one in two weeks. Began with gr. $\frac{1}{36}$ t.i.d., and increased the dose in a few days to gr. $\frac{1}{12}$ t.i.d. In the females H. H. was discontinued after two weeks, and in the males after four weeks, because of anorexia and nausea, loss of accommodation, dilatation of pupils, flushing of face, dryness of throat, and general languor and malaise produced by the drug.

If anything, the seizures are made more frequent. We were led to try it in epilepsy by the one benefited case of Edlessen, and by the laudation of its isomeride, atropine, by Trousseau, and by the praise of its other isomeride, hyoscyamine, in the West Riding Reports, as remedies in this disorder.

Conclusions.—We had hoped to be able to add hyoscine to our hypnotics, because its tastelessness would have made it especially valuable. That, however, is no virtue in the remedy, because of its uncertainty of action and the length of time it requires to produce sleep (sometimes one to two hours) when given by the mouth.

Hyoscine is not, in our opinion, a real hypnotic, such as chloral, opium, and the bromides, although it disposes to sleep by causing muscular relaxation and a feeling of weariness, and does, in large doses, produce stupor.

The sleep apparently caused by it is of short duration, and is easily broken.

We think it should never be given by the mouth with the view of producing sleep. We shall use it hereafter only hypodermatically.

Its continued use is not advisable.

Constitutional effects appear in some cases sooner and more severely than in others.

The respirations are made shallower but not diminished in number (any more than by natural sleep).

The pulse is often considerably reduced, sometimes increased in frequency, and usually made very variable. It may reduce or increase arterial tension. The face usually flushes, and the extremities become cold.

There is dilatation of the pupils and loss of accommodation. There is, further, dryness of the throat and mouth, dizziness, and in many cases, anorexia and nausea, in some cases vomiting and diarrhœa.

In a few cases there is sensation of heat and itching of the skin.

The severer effects are muscular tremor, unsteadiness of gait, delirium, and stupor.

It seems in one or two cases to have increased erotism.

As to its use in insanity, we tested it chiefly, as before stated, in these cases for its value as a hypnotic. We think, as a rule, it increased excitement by continued use. It made our melancholiacs worse. It was no improvement in chronic mania, dementia, and general paresis, on chloral and hyoscyamus. It was of no value in epilepsy, but may not have been continued sufficiently long. It may prove of value in some cases of acute mania if given subcutaneously; but we doubt if it will supersede hyoscyamine.

Poughkeepsie, N. Y., September 1, 1885.

Oxygen, it seems, can, after all, be brought to the liquid state, under such easy conditions that the experiment is likely to become an ordinary laboratory one, in consequence of a recent discovery by M. L. Cailletet. He has found that formene, when slightly condensed and cooled in boiling ethylene under atmospheric pressure, is resolved into an extremely volatile colorless fluid, which, while again passing to the gaseous form, produces cold sufficient to cause the liquefaction of oxygen immediately.

OBSCURE AND EARLY SYMPTOMS IN GENERAL PARESIS.

Case, with Remarks on the Diagnosis, Causes, and Early Treatment of the Disease.[1]

By RALPH L. PARSONS, M.D.,

new york.

Early in July, 1879, I was requested to visit a man named Jacob K——, for the purpose of rendering my aid in placing him in an asylum for the insane. His wife said to me, that although his conversation and actions were such that the members of his own family had no doubt regarding the deranged condition of his mind, many casual acquaintances who saw him, including some practitioners of medicine, failed to observe any evidences of insanity.

On visiting the patient two important sets of symptoms were observed: *first*, certain peculiarities in his articulation, or rather in his whole manner of speaking, in his expression, and in his movements, especially the movement of his tongue and his locomotion; and *secondly*, certain defects of the memory and of the intelligence which were evidently inconsistent with the theory that these defects were natural, for he had been an active and successful man of business, and, moreover, his manner and expression were quite different from what are observed in cases of original defect.

None of these symptoms were strongly marked, and at times none of them would be noticed by ordinary observers. Indeed, the members of his own family do not appear to have noticed his physical defects until their attention had been sharply drawn to the subject by close questioning.

The symptoms observed were, more specifically, as follows, viz.:

There was a certain peculiarity in his *articulation* which it is difficult to describe, as it was manifested only in a slight degree at any time, and at times was hardly observable, but which when its existence can be made out, is the earliest and one of the most important of the physical symptoms of a grave and fatal disease of the nervous system. This peculiarity in articulation did not consist in stammering, nor an inability to enunciate difficult combinations of consonants, nor even in that slight degree of stammering which may be characterized as a slowness or hesitation in the articulation of the whole or part of a sentence, as though stammering were imminent, but avoided by especial painstaking at difficult points; but rather by a sort of drawl and lack of clearness in the articulation of difficult words and phrases, of the existence of which the speaker did not seem to be conscious. When his attention was aroused, the defect in articulation was diminished.

The *tongue*, when protruded, lacked somewhat in firmness and steadiness, as though the muscles were enfeebled, or not well under the control of the will, and at times slight fibrillary tremors at the edges were observed.

His manner of walking lacked in firmness and decision. He did not stumble nor stagger, but walked wide, and as though the muscles of the legs were rather slow in receiving and obeying the mandates of the will.

No inequality nor irregularity of the *pupils* was observed, but they seemed to be rather large, and rather slow in responding to the stimulus of light.

When questioned he gave revelant, rational, and apparently correct answers; at all events, this was the case when he was questioned by strangers, and when short replies only were required. In fact, under these circumstances, he appeared to converse naturally enough, and to give no especial evidence of mental impairment.

But when the conversation was prolonged, and carried on in a familiar way; and when he was allowed to converse in accordance with his own impulses, certain marked peculiarities were observed. He would talk of

[1] Read before the Yorkville Medical Association.

trivial matters, as though they were of great importance, and yet in a childish way. Indeed, a lack of intellectual ability was then observed in both the matter and manner of his conversation, which was not at all in accordance with what was to be expected of a man of his appearance, and who had been a successful business man. Again, not only were the subject-matter and manner of his conversation childish, but he would repeat the same unimportant statements many times within the duration of a short conversation of an hour, without seeming to realize or to remember that he was thus repeating.

Here, then, we have a patient presenting certain not very well-marked mental and physical symptoms, who is thought by his relatives to be of unsound mind, but who is considered as quite sane by many of his casual acquaintances. His relatives claim that he sometimes manifests much more convincing evidences of insanity; but, inasmuch as they wish to place him in an asylum for the insane, how can the examining physician be sure that they have no motives of interest to place him there, and that their statements are reliable? If he depends on their statements as the basis of his opinion, he may render himself liable to a suit at law for assisting in the incarceration of a sane man.

It is important, then, to inquire whether such obscure symptoms, as have been enumerated above, are sufficient as a basis for the diagnosis of mental derangement; and if so, to what particular category this derangement belongs.

The mental symptoms, in so far as their character can be expressed in language, denote general enfeeblement and nothing more. He comprehends rather slowly; he is rather slow in giving expression to his ideas; he talks about unimportant, childish matters, or about serious matters in a childish way, as though he did not appreciate their importance; he forgets the subject-matter of a short conversation to such an extent that he repeats the same story many times during his conversation, and, moreover, the whole manner of his conversation and expression are such as to convince the observer that the will-power is weak. He finds that the patient is easily influenced by the will of others, notwithstanding the fact that at the first he sometimes appears to be particularly obstinate in regard to matters which may be in question. The physical symptoms are such as denote a general impairment of nervous energy.

What, now, do all these symptoms mean, for it is at least evident that the patient is in an abnormal condition? In making out a differential diagnosis there are several possibilities which should be borne in mind and duly considered. It might be a case of acute alcoholism, or of chronic alcoholism, or of acute or consecutive dementia, or of epilepsy, or of cerebral tumor, cancer, or exostosis, or of partial recovery from cerebral hemorrhage, or of progressive muscular atrophy, or of labio-glosso-pharyngeal paralysis, or if neither of these, of that general impairment of the whole nervous system designated by the term general paresis.

The symptoms enumerated correspond very closely indeed with those manifested by certain cases of alcoholism, whether acute or chronic. But when it is found that the condition of the patient persists from the date of one visit to that of another, although the evidences of the recent imbibition of alcohol are wanting at each, the immediate effects of drunkenness may be excluded. So, too, the headache, the trembling, and the hallucinations peculiar to chronic alcoholism are wanting. Local brain affections, such as tumors, softening, hemorrhage, etc., may also be excluded, for the reason that in these cases the paralysis is unilateral, and has a tendency toward improvement, save perhaps in the later stages when death is impending or a considerable portion of the brain is involved. Epilepsy has its peculiar physiognomy, and the mental and physical symptoms are subject to marked variation in accordance with the time which has elapsed since a seizure. In dementia, whether acute or consecutive, the degree of stupidity is much greater than during the early stages of the disease in question; and, moreover, such defects as there may be in the articulation or locomotion in the simple dement evidently arise from the absence of an exercise of the will-power rather than from a lack of response to the volition which is actually exercised. In progressive muscular atrophy muscle after muscle is consecutively affected, and the intellect is rarely impaired otherwise than is likely to occur in connection with any disease attended by physical enfeeblement. In glosso labio-pharyngeal paralysis there is indeed a general muscular enfeeblement corresponding very closely with that of the disease in question, but the mental symptoms are wanting.

There is one other disease, the leading symptoms of which perfectly correspond with those presented by the case under consideration. These are, in the concise language of Dagonet, *a paralysis which is general, incomplete, progressive, and accompanied by embarrassment of speech and mental disorder.* These are the essential symptoms of general paresis, or, as the disease is often termed, of general paralysis of the insane; and all these symptoms were manifested by the patient whose case has just been related, and may be considered as sufficient to establish the diagnosis, although the more characteristic of the mental symptoms peculiar to general paresis were entirely wanting, and although the physical symptoms were not very well marked. That is, we found a paralysis which affected all the muscles as far as could be made out, but most noticeably the muscles engaged in articulation and in locomotion. It should be borne in mind that if the whole nervous system be equally weakened in all its parts, the weakness will be most apparent in those movements which are the most delicate and require the nicest co-ordination. The movements required in the process of articulation are the most delicate of any of the muscular movements; and hence the weakening of nerve-power in general paresis may be noticed in a disorder of the muscular movements required in articulation sooner than in any other of the muscular movements, so the peculiar defect in the articulation may be diagnostic before other movements are noticeably impaired. We observed, also, that the paralysis was incomplete, was, in fact, slight; also that it remained the same from the date of one visit to another, so that if it did not noticeably progress within the space of a few days it was at least persistent. The mental disorder was also present.

In the great majority of cases of general paresis the mental disorder is characterized by exaggeration of ideas of a peculiar and extraordinary kind. The emotions are expansive, or at least are not depressed. And, moreover, the exaggerated ideas are entirely lacking in precision and definiteness. The patient will at one moment say he is worth a million dollars, and the next that he is worth a thousand millions; or now that he can run a mile in a minute, and immediately afterward that he can run a mile in a second. The essential element in the mental disorder is a weakening of the judgment and of the reasoning faculty; the patient is not able to compare one of his statements with another and to appreciate their discrepancy. Hence if his emotions are expansive he is very likely to express extravagant ideas, which are very indefinite and changeable in character, or he may only express entire satisfaction with his condition, prospects, and surroundings, when the facts would warrant only dissatisfaction. In some cases the emotions are depressed, but in these cases also the essential element—the weakening of the intellect—may be observed no less than in the others.

In most cases the testimony of friends and acquaintances may be safely relied upon to aid or substantiate the diagnosis. In the present instance this testimony was not necessary, and hence has been omitted in order that the essentials might be the more prominently brought into view.

As, however, a knowledge of the causes of the disease

and of the early symptoms is of especial importance to the general practitioner of medicine, a brief reference will now be made to some of these. After the symptoms of general paresis have become well marked, the disease may be of great interest to the pathologist, but is of little to the therapeutist; for in its advanced stages it marches surely and steadily to a fatal issue, notwithstanding any remedial measures that may be employed. If therapeutic or prophylactic measures are to be of any avail, it must be during the earlier stages, when the symptoms are most obscure and least likely to be observed.

Among the earlier symptoms of general paresis the following may be mentioned as the most common and the most important, viz.: The patient is observed to make extravagant or silly expenditures in opposition to his usual habit, or he neglects his business, while, at the same time, he takes unusual business risks, or he indulges in idle, impracticable schemes. In all this there is manifested at the same time an exaltation of feeling and a failure of the judgment very much like what is observed in many men when somewhat under the influence of alcoholic drinks. He may talk rather disconnectedly and more excitedly than is in accordance with his usual habit, or commit small thefts of articles he does not want, or which he could readily procure by purchase or simply by asking for them. An observer who has been led to suspect the possible existence of the disease may also be able to detect a slight embarrassment of the speech, this being the earliest of the physical symptoms, or even a noticeable carelessness in his chirography, or the omission of letters or words in his writings, or even that the movements of his extremities are not well co-ordinated. The mental symptoms, however, are almost always the earliest to show themselves, and the most prominent during the accession of the disease. Usually these premonitory and early symptoms are of considerable duration—a year, a year and a half, and, in some cases, a longer period of time.

At this point it will be well to enumerate some of the more prominent causes of the disease, since a consideration of these in connection with the early symptoms above mentioned will very materially aid in arriving at a proper diagnosis.

The following may be considered as types of the causes of general paresis, viz.: great business success, or the long-continued and ardent expectation of great success; great business losses, or long-continued anxiety about impending business losses; or alternating hopes and fears of success or failure; the intemperate use of alcoholic drinks; and excessive venery. It will be observed that all these causes act very powerfully on the emotions. Even the use of alcoholic drinks, although a physical cause, is a powerful excitant of the emotional part of our nature, and when efficient as a cause of general paresis may act in essentially the same way as do the other causes mentioned. Assuming the theory to be true that the whole nervous system is impaired in general paresis, it is still not at all impossible that long-continued emotional excitement may be at least one of the most important of the causes of this disease. At all events, the emotional element seems to be well marked among the mental causes.

So, then, when the practitioner of medicine observes the premonitory and early symptoms above enumerated in the case of any of his patrons, and more especially if he knows or ascertains that the individual in question has been subject to the causes which in many cases produce general paresis, he may have a reasonable hope of attaining curative results which are rarely if ever attained during the later stages of the disease. The fact that, contrary to the general experience, some cases of general paresis do sometimes apparently recover from what seemed to be a well-marked and hopeless stage of the disease, fairly warrants the hope that if the general practitioner of medicine were able to recognize the obscure and premonitory symptoms at an early day, he might in some cases save his patient from a calamity which otherwise would be practically inevitable.

The first step would evidently be to convince the patient and his friends that a grave disease was impending, and that prompt measures must be taken to prevent its accession. This task, which will usually be found a difficult one, will in most cases be best accomplished by an authoritative statement, unsupported by reasons. The simple statement of a professional opinion often carries weight which it would lose if accompanied by the reasons on which the opinion is founded; for the facts adduced may not be perceived at all by the non-professional mind, or if the existence of the facts be granted, the conclusions deduced may not be acknowledged. Indeed, it is not possible for a skilled observer to make scientific facts clear to the unlearned as he himself perceives them.

The first step in the treatment of the patient will evidently be to remove the causes which have been efficient in producing the mental and physical disturbance, or if this cannot be done, to diminish or counteract the causes as much as possible. If he is engaged in engrossing and prosperous business pursuits or speculations, he should either relinquish business entirely for a time, or should at least diminish or change his business to one of moderate dimensions, in which the risks are insignificant, and the profits moderate and regular. If he has been subject to great business losses and anxieties, it is better for him to save all he can from the wreck and retire from business entirely, rather than run the imminent risk of destroying himself in the vain endeavor to retrieve his failing fortunes. When the judgment becomes impaired, as it always is in these cases, the successful accomplishmen of difficult undertakings is entirely out of the question. There is great risk of failure, even in the pursuit of routine and hitherto prosperous occupations, and for this reason the interests of his family require that all his business operations be in some way placed under efficient supervision.

If the intemperate use of alcoholic stimulants or excessive venery be the cause of the commencing disease, these habits must be relinquished. In fine, all pursuits and habits that strongly affect the emotions should be given up.

The difficult task having been accomplished thus far, the remainder of the treatment will be comparatively easy. His physician should direct a life of quietude and a strict observance of hygienic rules. And inasmuch as the nervous system has become generally enfeebled, he should enjoin a plain, nutritious diet, and should prescribe such nerve-tonics as in his judgment seem to be required. The food tonics seem especially to be indicated in these cases. But while prescribing a nutritious diet, the quantity of food eaten should be moderate, and particular directions will be needed in this regard, inasmuch as these patients are inclined to eat voraciously. So, too, a constipated state of the bowels is to be guarded against, as well as all other departures from a state of health.

The importance of this subject to the general practitioner of medicine is manifest, when it is considered that the condition of general paretics is often practically hopeless by the time the disease has so far advanced as to attract the attention of friends and ordinary observers, and also that during the early period of the disease the paretic is likely to waste his property and impoverish his family.

In conclusion, it may be of interest to briefly recount the prodromata, early symptoms, and causes in the case which has served as a text for the preceding remarks.

The patient, who had been a prosperous wholesale butcher about four years ago, met with serious business reverses. He was obliged to give up the house in which he lived and which he owned. He was greatly annoyed by his misfortunes, and was unwilling any longer to as-

sociate with the men who had known him in his prosperity. His emotions were depressed instead of being expansive, as is usually the case in general paresis. He moved from New York to Brooklyn, and opened a retail butcher store. It was soon observed, however, that he did not conduct his business with his usual discretion. He systematically bought greater quantities of meat than he could sell, notwithstanding the fact that his wife and children made constant remonstrances against his indiscreet purchases, and the fact that so much meat spoiled on his hands as to more than counterbalance the profits. He lost his trade altogether in less than a year, and removed to Williamsburg, where he opened another store, with a competent head-man in charge. Business went on well for a time, but then he began to buy excessive quantities of stock as before. He also began to change his workmen in the store every two or three weeks, although he had formerly kept the same men in his employ for years together. He was also rude to his customers, and would sell them meat that had already spoiled. His memory, as well as his judgment, was observed to be at fault, for he would often send meat away without making any account of the purchase, unless closely watched by his daughter, who acted as bookkeeper.

He was eminently social in his habits when in a state of health. He had now become disinclined to seek society, and complained that his former associates treated him with neglect after he became unfortunate. When his children were merry and laughed, he would reproach them for their light-heartedness.

His business failed in Williamsburg as it had failed in Brooklyn. So in January last he removed to New York, and again established himself in business there, but his lack of judgment was still more marked than before. He hired a store utterly unfitted for his business, and mismanaged his business to a greater extent than ever.

His friends had never suspected that his mental faculties were impaired until this time, but now his conversation and conduct became such that the members of his own family were convinced of this fact, although casual acquaintances even then failed to recognize evidences of insanity.

It is proper at this point to mention one other probable cause of his disease, that is, the frequency of his devotions at the shrine of Venus. This was inferred from evidence which was considered reliable, but which it is unnecessary to state.

The issue of the case was as follows: An unfavorable prognosis was given. On July 19th he had a series of epileptiform convulsions, such as usually occur at some time during the progress of general paresis. An overloaded and constipated state of the bowels was probably the immediate cause of the convulsions. Croupous pneumonia, with general pulmonary congestion supervened, and the patient died on July 24th.

THE PATHOLOGICAL RESULTS OF MIMICKING PASSION.—Mme. Bernhardt has written an interesting letter in defense of the sincerity of actors and actresses, seeking to prove that many of them really enter into the spirit of their parts. She declares that Croizette, after the famous poisoning scene in "Le Sphinx," used to remain for some minutes pale and with chattering teeth, that Beaulevet always wept real tears when performing *King Lear*, and that Mounet-Sully had veritable hallucinations when acting the madness of *Orestes*. Sarah herself seems to outdo all these celebrated examples. She says: "I have never played *Phèdre* without fainting or spitting blood, and after the fourth tableau of 'Théodora,' in which I kill *Marcellus*, I am in such a nervous state that I return to my dressing-room sobbing. If I do not weep I have a hysterical fit, which is much more disagreeable to those around me and more dangerous for the vases and other things near at hand."

SPECIMEN OF DECIDUA,

ILLUSTRATING THE RESEMBLANCE BETWEEN THE PHYSIOLOGICAL DECIDUA OF PREGNANCY, AND THE MENSTRUAL OR PATHOLOGICAL DECIDUA OF VIRCHOW.

BY ALEXANDER J. C. SKENE, M.D.,

PROFESSOR OF GYNECOLOGY, LONG ISLAND COLLEGE HOSPITAL, BROOKLYN, N. Y.

THE interest in this specimen depends upon the fact that it may help to settle the question regarding the pathology and etiology of *desquamative dysmenorrhœa*, so called, which is still an open question among pathologists.

FIG. 1.

I obtained this specimen from a patient who aborted in the second month of pregnancy. It consists of the ovum and the exfoliated uterine mucous membrane or decidua. Fig. 1 shows the entire specimen, the membranes being laid open at *A*, to show the ovum *in situ*. The dotted line represents a portion of the membrane which was broken; and although the shreds of the broken portion were obtained, they could not be put together to show the complete cast. *B* shows the opening in the cast which represents the os internum.

Fig. 2 shows the membrane laid open and the ovum turned upward, the dotted line again indicating the lost portion of the membrane. The membrane looks exactly like the membrane which has been obtained in so-called membranous dysmenorrhœa, except that it is thicker at the point where the ovum was located.

The microscopical examination of this decidua shows that the membrane resembles the lining of the uterus, hypertrophied in all its elements. On the uterine surface of the membrane there was evidence that fatty degeneration had taken place, which evidently was the cause of the abortion and complete exfoliation of this membrane or decidua.

FIG. 2.

I presume it is rather rare that a specimen of this kind is obtained, from the fact that the decidua is not always thrown off in mass in abortions, at this early stage of pregnancy. It, therefore, gave me an unusual oppor-

tunity for studying its resemblance to the pathological condition of menstruation referred to.

From this comparison I have received valuable evidence in favor of the views of Professors Simpson and Virchow, which I had already accepted as correct, namely, that the membrane exfoliated in this abnormal form of menstruation was the same in character as the normal decidua of utero-gestation. Taking this one fact regarding the decidua of pregnancy and the character of the decidua of a normal menstruation, it is more than probable that this menstrual decidua is the product of a heightened or excessive physiological process, which occurs out of time and out of season, a view which was entertained and taught by Sir James Simpson. It is also very valuable evidence against the theory entertained by others, that this membrane of menstruation is the product of an inflammation.

It appears, then, that in this disorder of menstruation the membrane repelled is a normal product of the uterus, which is pathological, because it occurs in the absence of pregnancy.

Now, let us take into consideration, at this point, the facts regarding menstruation as taught by Williams, of London, and Engleman, of this country: that the mucous membrane of the uterus attains its highest development at the period of menstruation, and that during menstruation it undergoes fatty degeneration, and is exfoliated either wholly or in part, that the exfoliation as it occurs in the healthy condition is in a granular or finely divided state; whereas in the pathological condition known as the membranous dysmenorrhœa, a fatty degeneration occurs in the deeper structures of the mucous membrane, and not in the whole of it; so that it is separated from the uterus by this stratum of fatty degeneration, and is thrown off in mass.

If, then, we draw our deductions from these facts, it would be proper to say, that in this affection of the uterus we have an excess of development of its mucous membranes, with a fatty degeneration limited to the deeper structures and not involving the entire membrane; which would account for it being thrown off entire, and not in the broken-down condition of normal menstruation.

If this, then, is the correct view of the subject, we can exclude inflammation as a factor in the production of this derangement of menstruation, and accept the fact that it is due to some abnormal excitation of the sexual organs, ovarian in all probability.

My clinical experience with some eight cases of membranous dysmenorrhœa would lead me to this conclusion as regards the etiology of the affection. In the majority of those where the cause has been noted I find that I have recorded that there was ovarian pain and tenderness in some of these cases, and in others it is recorded that there was no evidence of any inflammatory affection of the uterus itself.

To my friend, Dr. R. L. Dickinson, I am indebted for the excellent drawings of the specimens.

A Clairvoyant's Mistake.—The great skill in doctoring claimed by clairvoyants was fully illustrated recently by a circumstance which happened in Sharon. An estimable lady, who had been sick for a long time with a cancer, which good physicians knew to be incurable, was induced to try a clairvoyant doctor. The one selected was a certain "doctor" of North Easton. He professed to be able to tell the exact condition of the patient without seeing her, and sent medicine and a diagnosis each week. Every letter stated that she was getting better. A few days after her death he evolved the following, which was received by the family:

"North Easton, June 11th.

"Mrs. ——: I find you about the same. The acid in the blood has rather diminished. Use the medicine and bathe the same. Keep along with the poultice."

Clinical Department.

COCAINE IN HAY FEVER.

Dr. G. H. Simmons, of Lincoln, Neb., has used cocaine for the relief of hay fever with marked success in several instances. He relates the following case: "A farmer came into my office about three weeks ago, and, in a discouraged manner, asked me if there was nothing I could give him to relieve him of that terrible suffering and annoyance. His eyes were bloodshot, and his looks showed that he suffered all that he claimed to. Every little while he would have an attack of sneezing, which lasted three or four minutes, after which there would be profuse perspiration. He complained of great shortness of breath, exhaustion, and dimness of sight. There was intense itching of the nares, frontal headache, and severe pain in the eyes. It was the eye trouble that suggested cocaine to my mind, and as I had only a few minutes before been using a two per cent. solution in a case of cystitis (and with success), I without hesitancy concluded to try it in this case. I dropped two or three minims of the solution into each eye, and the effect was almost miraculous. I then with a camel-hair pencil applied a few drops to each nostril and well back into the posterior nares. The relief was immediate and complete. I gave my patient two drachms of the solution and instructed him how to use it. I saw him again in ten days, and his praises in favor of the remedy were very profuse. He had used it about three times a day, and thus kept off all symptoms of his annual trouble. It was the first time he said for years that he had been free from it during the latter part of July and the first two or three weeks of August. A second case in which the same remedy was used was hardly as severe, but the relief was just as complete and satisfactory. The patient is a married lady who has never found relief before without going either to the lakes or the mountains. In this case I used a four per cent. solution." Dr. Simmons has also employed cocaine in a five per cent. solution in equal parts of vaseline and castor-oil, as recommended by Dr. Gelston, of Limerick. He was successful, but nevertheless prefers the simple aqueous solution. He notes that Mr. John Watson, of London, has obtained relief in his own case by the use of tablets of cocaine inserted into each nostril.

THE TREATMENT OF TÆNIA BY CHLOROFORM.

Dr. W. H. Bennett, of Brooklyn, N. Y., sends us the following: As there has been some considerable discussion during the past year regarding the efficacy of chloroform in either killing or completely anæsthetizing tapeworm, so that its expulsion is rendered an easy matter by the simultaneous or after-administration of a brisk purgative, I beg to call attention to three cases where the drug mentioned was primarily successful in bringing about this result.

The first case was that of a girl, aged fifteen, whom I had previously dosed with most every known tænicide, with the result each time of bringing away a portion of the worm, but always minus the head. On July 10, 1884, I administered half a drachm of chloroform in two ounces of mucilage, and in half an hour afterward one ounce of castor-oil. At about noon the bowels moved freely and the parasite was expelled entire.

Case No. 2 was an adult, aged fifty-two. He had also been subjected to treatment by male fern and other drugs, but unsuccessfully. On January 25, 1885, I ordered him half a drachm of chloroform as above mentioned, followed by an ounce of castor-oil, and within four hours the whole worm was passed.

Case No. 3 had suffered from the presence of a tænia for a year and a half. Had tried many remedies without

avail. I gave him the same quantity of chloroform, but combined the castor-oil with it. The result was entirely satisfactory.

All three patients have remained well since. In each case the patient was allowed to eat a light supper and the medicine was given before the breakfast hour in the morning; no food being allowed till the bowels moved. The only disagreeable symptoms caused by the chloroform were in one case slight nausea and in all a trifling sense of intoxication with slight headache and somnolence, which passed off in a couple of hours after the oil operated. No further discomfort was complained of.

It will be noticed that half a drachm was the largest quantity of chloroform used. In case this should not prove sufficient, I would prefer, in subjecting the patient to treatment at a subsequent time to administer a second half a drachm some twenty minutes or half an hour after the first dose of a like amount of chloroform, or even several subsequent doses of a few drops each, at intervals of some minutes, than to give more than the maximum quantity here mentioned. By this latter method the effect on the worm might be equally as great, while the action of the drug on the heart would not be as likely to produce the alarming symptoms which have been reported where doses of one drachm or more have been given.

Progress of Medical Science.

Regressive Locomotion.—Dr. Luigi Mazotti relates' in *La Rivista Clinica* for June, 1885, the case of a man, sixty-six years old, admitted to hospital for scurvy. He had always been a hard drinker, but had enjoyed good health up to the age of fifty-five, at which time he had an illness which lasted for five months and left behind it a lowered general condition of health. In 1882 he suffered from an attack of sudden loss of consciousness of short duration. Since that time he had experienced dizziness occasionally, but had not fallen. He had been gradually growing weaker up to the period of admission to hospital. After being under treatment for scurvy for a time, his general condition began to improve, and orders were given that he should be allowed to get up and walk about the ward. It was then discovered that he could not take a step in advance, but walked backwards. When placed upon his feet he seemed a little unsteady, looking down to the ground and separating his legs as if fearing to lose his equilibrium. When taken by the arm and told to walk he responded that he was unable to do so, and when commanded to try, he took several steps backward, moving his legs with an appearance of exertion as though they were held. After having gone a short distance in this manner, the body became arched backward, and rotated from the right toward the left, and the man would have fallen if he had not been supported. At another time, after having been dragged forward by two of the orderlies, he was told to go ahead by himself. But as soon as his arms were released by the attendants he began to turn around in a circle with the right leg as the axis. When the patient was in bed he was able to execute all voluntary movements without difficulty, the special senses were normal, tactile sensation was good, though not very acute, and the tendon reflexes were a little exaggerated, especially on the right side. The patient died not long after of an acute intestinal trouble. At the autopsy was found a slight amount of leptomeningitis over the vault, evidently of recent origin. There was, further, marked atheroma of the arteries at the base of the brain, but beyond that nothing. The cerebellum, pons, medulla oblongata, peduncles, etc., were all normal, and bore not the slightest evidence of disease. Owing to certain legal difficulties it was impossible to secure the spinal cord, but a good portion of the upper end was examined with negative result. But the patient presented no symptoms of tabes dorsalis or of any other recognized spinal lesion. In view of these facts the author was forced to conclude that the phenomenon of regressive locomotion was dependent, in this instance, at least, to circulatory disturbances. The existence of these was rendered most probable by the fact of the extensive and marked atheroma, and were probably exaggerated by position when the patient rose to his feet. Dr. Mazotti therefore concludes with Nothnagel that the clinical symptom of regressive locomotion is of no value as a diagnostic sign in a localized cerebral lesion.

Ichthyol.—This is a bituminous substance, found in the Tyrol, and formed from the remains of antediluvian fishes. Its chemical constituents are carbon, hydrogen, oxygen, sulphur (ten to sixteen per cent.), and phosphorus (0.5 per cent.). It has the appearance of tar, is about of the consistence of vaseline, is slightly soluble in water, alcohol, and ether, and is miscible in all proportions in oils and vaseline. Owing partly to its large percentage of sulphur it is found to be of value in the treatment of skin diseases, and especially of acne rosacea. In the latter disease it is used externally and internally, and even sometimes hypodermatically. For internal use a solution is made of five to ten parts of ichthyol to twenty parts of distilled water, the dose of which is fifteen drops, gradually increased to fifty, twice a day in water. An ichthyol soap is also made, and recommended strongly by Unna (*Volkmann's Klinische Vorträge*, No. 252) in the treatment of acne. It is useful also in burns and other traumatic lesions of the skin. Lorenz (*Deutsche Medicinische Wochenschrift*, No. 23, 1885) has found it of value, externally applied, in relieving the pains of chronic articular rheumatism, using for this purpose an ointment of the strength of thirty per cent. Internally, ichthyol acts as an aperient, and has also been used with apparent benefit in gastritis in doses of two to three grains twice a day. The wide range of applicability of this medicament is to be explained by the property which it seems to possess in a remarkable degree of subduing inflammatory processes.

Double Renal Artery with Thrombosis of one of the Trunks.—Dr. Luigi Mazzotti reports in the *Bulletino delle Scienze Mediche di Bologna* the case of a woman, sixty-six years old, admitted to hospital suffering from very severe pains in the epigastric and hypochondriac regions, accompanied by a slight elevation of temperature, extreme thirst, dyspnœa, œdema, and delirium. The urine was albuminous and contained a considerable quantity of blood. The general condition improved somewhat under treatment, but about a month after admission the patient was seized with uncontrollable diarrhœa and vomiting, and died in a few days. At the autopsy the right kidney was found to be supplied by two arteries, and to have two ureters. There was but one vein, however. The supernumerary ureter was very small and united with its mate before entering the bladder. One of the arteries was pervious, while the other was closed throughout its entire extent by a thrombus. The right kidney presented in general a normal appearance, though of a somewhat redder color than usual. In the upper part, however, was a spot about two-fifths of an inch in diameter, in which the cortical substance presented a pale gray color. Microscopical examination showed that this was due to a granulo-fatty degeneration of the tubular epithelium. Examination of other portions of this kidney and of the one on the left side showed no pathological changes.

Succedanea of Cocaine.—Since the discovery of cocaine and its anæsthetic properties, numerous experiments have been made with other substances, but the only ones which have, as yet, been found to have a similar effect are apomorphine and menthol. Bergmeister and Ludwig (*Bull. Gén. de Therap*, July 30, 1885) found that in about ten minutes after the instillation of six to eight drops of a two per cent. solution of apomorphine

there was complete anæsthesia of the conjunctiva, lasting for from five or ten minutes to an hour. This was accompanied by dilatation of the pupils of somewhat shorter duration. But the first effect of the solution was to cause a sensation of pain and smarting. The hydrochlorate, lactate, and pure apomorphine were used at different times, and all had the same temporary irritant action. Another unpleasant symptom caused by the action of the drug was nausea. The subjects were also frequently left with a sensation of fatigue which lasted for several hours. Unless these inconveniences can be obviated in further experiments, it is not likely that apomorphine will ever become a formidable rival of cocaine as a local anæsthetic, but it is, nevertheless, well to know that it possesses this property, as cases may arise in which its employment would be of great utility. Rosenberg (*A Medicina Contemporanea de Lisboa*, August 2, 1885) has used menthol, in a twenty to thirty per cent. alcoholic or ethereal solution, with success. The effect of menthol is not of as long duration as that of cocaine; but the former seems to have a sort of cumulative action, as when the application is repeated, even at long intervals, the anæsthesia produced by the last application is of much longer duration than that following the first.

Belladonna as an Antidote of Iodide of Potassium.—In three cases in which iodide of potassium caused unpleasant naso-pharyngeal symptoms, Dr. P. Aubert found entire relief afforded by extract of belladonna in doses of three-fourths of a grain, morning and night. He found even that, after the use of belladonna for a few days, it could be discontinued without a return of the symptoms of iodism.—*La Independencia Médica*, August 1, 1885.

Decoction of Lemons in Gonorrhœa.—Dr. Rebatel recommends this simple remedy, first suggested by Mannino, and affirms that it quickly destroys the vitality of the gonococci. Three fresh lemons are cut up into small pieces and put into ten ounces of water, which are then boiled down to three ounces. The liquid is then strained and used as an injection repeated three or four times a day. The decoction should be freshly prepared every second day. Instead of this decoction may be substituted a solution of one grain of salicylic acid and twenty-five grains of citric acid in eight ounces of water. —*Rivista Clinica e Terapeutica*, August, 1885.

Albumen in Chronic Diarrhœa.—Dr. Celli speaks highly of albumen in the treatment of enteritis. The whites of a dozen to eighteen eggs are beaten up with about a quart of water, and the whole taken at different times through the day, a few drops of laudanum being added if there is very severe pain. The author has used this remedy with success in a considerable number of cases of chronic diarrhœa which had resisted the action of all other remedies.—*Il Movimento*, June, 1885.

The Operative Treatment of Club-foot.—In an article on this subject Dr. Lorenz reviews the different operations which have been proposed for the correction of talipes. Of these there are fourteen, exclusive of tenotomy, as follows: 1, Linear osteotomy of the scaphoid practised on the plantar surface (Hahn); 2, linear osteotomy of the tibia above the malleolus (Hahn); 3, enucleation of the cuboid (Solly); 4, enucleation of the astragalus alone (Lund, Maron); 5, the same with resection of the tip of the external malleolus (Maron, Reid); 6, excavation of the spongy portion of the astragalus, leaving the articular surfaces (Verebely); 7, enucleation of the astragalus and excision of a wedge-shaped piece from the anterior portion of the os calcis (Hahn); 8, enucleation of the astragalus and cuboid (Albert and Hahn) or of the astragalus and scaphoid (West); 9, enucleation of the astragalus, cuboid, and scaphoid (West); 10, enucleation of the cuboid and scaphoid (Bernet); 11, resection of the head of the astragalus (Lücke, Albert); 12, excision of a wedge from the outer half of the neck of the astragalus (Hüter); 13, excision of two wedges, perpendicular to each other, with bases at Chopart's articulation and the astragalo-calcanean joint (Rydygier); 14, excision of a wedge without regard to any individual bones (O. Weber, Davies Colley, R. Davy). Of all these the only ones which the author regards with favor are enucleation of the astragalus in young children, and No. 14 in adults. He says, however, that Rydygier's operation gives good results in certain cases.—*Lo Sperimentale*, July, 1885.

Napelline in Toothache.—Dr. Grognot relates a number of cases in the *Bulletin Général de Therapeutique* of July 30, 1885, in which he administered napelline internally for the relief of odontalgia. In most of the cases the pain was directly traceable to caries, but in some it seemed to be more purely neuralgic in character. The napelline was given in granules of one-twelfth of a grain each, repeated every fifteen minutes. In most of the cases reported, the pain had ceased after five or six granules had been taken. The author urges the necessity of using only pure napelline, and advises that not more than twelve doses, or one grain, be given.

Chloral in Albuminuria.—Dr. Barduzzi has obtained excellent results with chloral in daily doses of thirty to forty-five grains, continued for some time, in the treatment of nephritis. Under its use œdema is reduced and the albumen nearly or entirely disappears from the urine. The author regards it as of especial value as a prophylactic of eclampsia in the albuminuria of pregnancy. It is also useful in the so-called physiological or normal albuminaria.—*Il Movimento*, Nos. 9–12, 1885.

Plantar Hyperæsthesia.—M. Barbillion describes a singular affection characterized by an excessive impressionability of the soles of the feet to various external influences. In one case the patient, a grocer's boy who was obliged to be on his feet the entire day, began, shortly after undertaking this work, to have acute pain in both feet toward evening. Soon the pain became continuous and was felt in the whole plantar region. It disappeared as soon as the patient got into bed, but would be brought back whenever in movements of the legs the soles of the feet were brought in contact with the bedclothing. Cold, in this case, brought a certain measure of relief. The reflexes were normal and there were no symptoms of ataxia. There was no redness nor swelling of the integument, and the perspiration was not abnormal in quantity. Three applications of chloride of methyl, one of which caused vesication, brought about a cure. In another case a cure followed the application of a blister covering the plantar surface. The writer reports other similar cases, and concludes that the affection is an idiopathic plantar anæsthesia, distinct from other painful diseases of the feet.—*Journal de Médecine et de Chirurgie Pratiques*, July, 1885.

Progressive Tabetic Contracture—The following are the conclusions of Dr. E. Demange to an interesting article in the *Revue de Médecine* for July, 1885: 1, There is a special form of tabes with contracture, distinct from spasmodic tabes and from amyotrophic lateral sclerosis, but yet having many points of resemblance to these affections; 2, this form is observed in extreme age, after the seventieth year; 3, its cause is to be referred to a special manifestation upon the spinal vessels of generalized atheroma; 4, anatomically it is characterized by an interstitial diffuse sclerosis, of vascular origin, of different parts of the cord and more especially of the lateral columns, without, however, ever being limited to this system alone; 5, clinically it occupies a position intermediate between spasmodic tabes and amyotrophic lateral sclerosis.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, September 19, 1885.

EUTHANASIA.

"THE kindest wish of my friends is euthanasia," wrote Arbuthnot, and the longing of many a sufferer ever since the world began has been for the same blessed boon. Bedside experience has convinced many a physician that this question is not a mere theoretical one. The wider our acquaintance becomes with the pathology of disease the more importance it is assuming. There are certain forms and stages of disease before which we stand practically powerless, though the feeling that "where there's life there's hope," often inspires us to keep the spark of life flickering as long as possible. But how often do we know beforehand that our efforts will be fruitless! We are obliged to content ourselves with endeavors to make the physical aspect of death as easy as possible for the senses of the patient, and the feelings of his friends. In the majority of cases nature mercifully benumbs the senses at the approach of dissolution, which is sometimes so gradual that it resembles falling asleep, "like one who wraps the drapery of his couch about him and lies down to pleasant dreams," as the author of "Thanatopsis" beautifully expressed it. Death-bed utterances generally occur in books. Indistinct murmurings of a moribund person are often vivified by imaginative friends into veritable utterances of one on the threshold of another world.

In many cases, however, of incurable disease no such euthanasia comes. There is to the very last a bitter struggle between sense and pain, as dreadful almost to contemplate as to endure. At this point comes up the practical consideration of the question, which in years to come is going to claim our attention more than it has done in the past. The mind of the laity, as well as of the profession, has already changed upon this matter; the assumption in both cases being—as in all matters concerning man's relation to the hereafter—toward a more liberal standpoint. Particular attention was called to the subject by the case of the distinguished patient who now lies quietly at Riverside. Fearless in the presence of any earthly foe, and asking no quarter, he had that natural shrinking from the painful death which his malady might have occasioned. He asked for and was promised a quiet end. No one questioned either the reasonableness of the patient on this point, or the wisdom of the assurances of his medical attendants.

What is euthanasia in relation to the office of the physician. It has been formulated by a member of the Birmingham Speculative Club, as follows: "That in all cases of hopeless and painful illness, it should be the recognized duty of the medical attendant, whenever so desired by the patient, to administer chloroform or other anæsthetic, so as to destroy consciousness at once and put the sufferer to a quick and easy death, all needful precautions being adopted to prevent any possible abuse of such duty, and means being taken to establish beyond the possibility of a doubt that the remedy was applied at the express wish of the patient."

One of the daily journals recently reported the result of interviews on the subject with several of the leading physicians of this city. All agreed as to the soundness and humanity of the views above stated, but no one cared to express a frank opinion as to how they should govern daily conduct. It is claimed that such a code of principles in nowise contravenes the laws regarding the sanctity of human life. Any man who sacrifices his life, say its advocates, to save another from lingering pain, is always reckoned a hero. Why should he not do the same for himself? In his own case the motive is, of course, lower. It may be styled a form of selfishness. The mere act itself is, however, regarded as justifiable in both cases.

The opinions of those consulted were unanimous in regard to the serious risks incurred in the adoption of any such principle. The latter's rigid enforcement would not allow for possible errors in diagnosis. In cases of carcinoma and phthisis no room for such doubt would exist. But there are many cases where (granting even that euthanasia should be demanded by the patient) no such thing would be thought of by the medical attendant unless his own affirmative judgment should be sustained by the result of a consultation; this argues a much more advanced state of professional opinion than obtains at the present time. Patients supposed to be *in extremis* have often recovered. The patient himself might not be in that state of mind where he could rightly judge concerning euthanasia, though it might possibly be indicated in his own particular case. Its enforcement would have to be under legal restraint. The further settlement of this question depends on the growth of public opinion. We cannot hasten it. For the present the guide of each man must be his own conscience.

A NEW DIAGNOSTIC TEST FOR THE TUBERCLE BACILLI.

THE importance of the bacillus tuberculosis in the diagnostic study of phthisis is now universally admitted. The methods by which this parasite is recognized are not elaborate or difficult to put in practice. Many physicians throughout the country, not microscopical experts, can and do make examinations for the purpose of discovering them. When they are numerous in the specimen there is little danger of error, but when only a few can be seen, the problem is more difficult. The lepra and the lupus bacilli quite closely resemble those of tubercle. The French observers Alvarès and Tavel (*Prog. Medical*, August 22, 1885) have shown apparently that there exists in normal secretions a bacillus resembling in many respects that of tuberculosis. Microscopists find, also, that bits of horny tissue from the horny layer of the epidermis, or particles of feathers floating in the

air will stain like the tubercle bacilli. Hæmatin crystals, according to Lustig, also may be taken for bacilli. Thus there are some sources of error in examining secretions which are poor in the special organisms.

Professor Voltolini, of Breslau (*Allgemeine Med. Centr. Zeit.*, No. 65), has discovered a method by which these sources of error can be eliminated. This consists in acting upon the preparation with fuming nitric acid, so that an appearance of chain-like spores is seen in the bacilli. The sputum, for example, is spread upon a cover-glass and dried as usual. The cover is then taken up with pincers and slowly dipped into the strongest undiluted nitric acid—acidum nitricum fumans. It is then slowly withdrawn and washed with pure water. The preparation is then dried and colored in the usual manner; but it is important to leave the cover in the staining fluid for from twelve to twenty-four hours. The layer of sputum, or pus, or the section must be quite thin, and the acid must be fresh and fuming. The bacilli so treated retain their form perfectly, but their interior appears to contain a chain of spores. The appearance, however, is thought to be due not to spores, but to an artificial coagulation. It is characteristic of the bacilli of tuberculosis, and, as Voltolini believes, of no other bacillus.

THE COMMITTEE ON THE INTERNATIONAL MEDICAL CONGRESS AND ITS WORK.

For the first time in its history the International Medical Congress has fallen into the sole management of a society of the country in which it is to meet. Although Sir James Paget, an ex-President, expressly affirms that this was not expected or desired when an invitation was given, yet it is evident from recent events that the society referred to intends to retain its hold, and force upon the Congress its own men and methods. The work of the Committee which met here in such secrecy on September 3d but too surely confirms this. Details of its mysterious labors are given elsewhere. These show some indications of adroit wriggling to escape the results of previous blunders, but no manly meeting of the issues, and no recognition of the real demands of the profession. The Committee have utterly eliminated and blotted out Drs. Cole and Shoemaker, trusting, we presume, to gain back Philadelphia by thus making scapegoats of these gentlemen. They have also filled the vacancies in the Presidencies of the Sections. Their list of names suggests both freshness and decay, but does not fairly represent American medicine. And the profession will very quickly ask who many of these new men are who thus take the seats which have heretofore been held only by recognized leaders? Is our country to be made ridiculous by their upheaval, and the Congress turned into a menagerie of unknown doctors and ethical sticklers?

However, though the appointments are weak enough, they need not kill the Congress. But a much more serious thing remains: no attempt was made to remove the Code issue from the Congress. It is still incumbent on an American physician to subscribe to the American Medical Association's Code of Ethics in order to hold any official position in the Ninth International Congress—if it meets in this country. The stupidity, as well as absolute wrongfulness, of failing to meet this point is certainly beyond parallel. The good Lord only knows, perhaps, what a number of nice, venerable, determined old gentlemen we have here trying to manage our little medical world; but many of us are getting some inkling of their immeasurable and fathomless fatuity. It appears, at any rate, that they are bound to destroy the Congress, for they persist in forcing upon it restrictions which cut off from the Congress and impugn the respectability of a large number of the most honored men in our profession. In thus doing they violate justice and right, break the pledges at Copenhagen, and affront their fellow-physicians here. Of course a bitter controversy is inevitable; and we are sorrowfully forced to the conclusion that there is at present no hope for the Congress whatever. The profession here and in other centres is almost a unit against the policy of the Association and its Committee, and it will continue to protest against the organization of a meeting which will be so thoroughly misrepresentative of American medicine.

A BEGINNING IN BACTERIOTHERAPY.

It is a fact well known to students of bacteriology, that certain forms of micro-organic life are inimical to each other, and will not thrive when together in the same culture-fluid. One form or the other, whichever is the stronger or the more suited to the medium in which it finds itself, will increase and flourish at the expense of the other, just as the weeds in a neglected garden grow up and choke the more tender plants, and appropriate to themselves the nourishment in the soil which the others need for their sustenance. Such being the case in cultures outside of the body, it is but natural to suppose that the same thing would occur within the organism. And if it be true that disease depends upon the presence of certain noxious microbes in the organs or tissues of the body, a rational means of combating the disease would seem to be to introduce other microbes which are fatal to the existence of the specific organisms.

This has actually been tried, with apparent success, in a case of pulmonary tuberculosis, by Dr. Arnaldo Cantani, of Naples, who describes his experiment in the *Giornale Internazionale delle Scienze Mediche*, No. 6, 1885. The patient was a woman, forty-two years of age, whose father had died of pulmonary disease. She presented the signs of a large cavity in the apex of the left lung, was suffering from hectic fever, and had an abundant purulent expectoration containing quantities of tubercular bacilli. She had been taking quinine, salicylic acid, cod-liver oil, etc., but continually grew worse and lost in weight and strength. Animals inoculated with her sputa became tuberculous. On May 4th, all the drugs which the woman had been taking were discontinued, and she began to inhale every day, by means of an ordinary atomizer, a mixture of gelatine and beef-broth containing a very rich, pure culture of bacterium termo. An almost immediate improvement was noticed, the expectoration became less, and the tubercle bacilli began to disappear, until on June 1st no more could be found in the sputa. As the tubercle bacilli became less numerous their place was taken by the bacterium termo. The tubercle bacilli had not reappeared at the time the report was made, and inoculations practised with the sputa upon animals failed to cause tuberculosis in them. At the same time with this apparent

local arrest of diseased action the patient's general condition improved, the evening rise of temperature was less marked, there was an increase of strength, and a gain of nearly a pound and a half in weight was noted.

Of course, one such case proves nothing. Patients with pulmonary tuberculosis, in common with sufferers from other diseases, are often dosed too much, and it is not uncommon to note a temporary improvement following the withdrawal of all medicine. Yet it is interesting as being the first attempt to fight microbes with microbes. And it opens up a large field of speculation to an imaginative mind in contemplating the future contests of the bacteria in the human battle-ground. Although, should such attempts succeed, we should behold one of the grandest achievements of this age of great discoveries, and Cantani, as the founder of bacteriotherapy, would rank among the immortals, yet there would be something humiliating in the thought that man could not cope single-handed with his infinitesimal foes, but was forced to call to his aid other invisible allies to fight his battles for him.

We shall look with interest for reports of further experiments of this nature, and we wish the bacterium termo success.

THE MONTREAL EPIDEMIC AND THE UTILITY OF VACCINATION.

THE present epidemic of small-pox at Montreal is furnishing incidentally some evidence as to the utility of vaccination. From August 1st up to September 14th, the total number of cases of small-pox at Montreal was close upon one thousand, and the number of deaths about three hundred and thirty. The very large majority of these victims were French-Canadian Catholics. Thus, out of one hundred and twenty-eight cases occurring last week, all but five were Catholics; while of the total number of deaths since August 1st, only thirty-four have been among Protestants. It appears that the Canadian Catholics, on religious grounds, do not allow themselves to be vaccinated. Hence, the force of the epidemic is spent upon them. No doubt uncleanly modes of life have something to do with the excess also.

THE AMERICAN MEDICAL PROFESSION *V.* THE ASSOCIATION.

THE real trouble in the case of the Washington Congress is that under the direction of a few gentlemen prominently interested in the American Medical Association, the local issue of the Code has been forced upon an international scientific body. There was no justice or right in this, and it was in violation of all precedent and of tacit pledges made at Copenhagen. The consequence of their action is that a large number of our country's best physicians are incapacitated from holding any position in the meeting, and, of course, cannot with self-respect take part in the work of a body which impugns their professional respectability. The profession has almost unanimously condemned this action. In proof of this we give here a list, which we believe is complete, of the journals in this country that have disapproved of the course of the Association: *New York Medical Journal*, *Boston Medical and Surgical Journal*, THE MEDICAL RECORD, *Chicago Journal and Examiner*, *Maryland Medical Journal*, *Medical Age*, *Philadelphia Medical Times*, *Louisville Medical News*, *Atlanta Medical and Surgical Journal*, *Virginia Medical Monthly*, *Indiana Medical Journal*, *Pacific Medical and Surgical Journal*, *American Practitioner*, *New Orleans Medical and Surgical Journal*, *Cincinnati Medical Journal*, *Columbus Medical Journal*, *Medical News*, *Kansas City Medical Index*.

We believe that there is not one of the few medical journals that defend the course of the present Committee which has not some official or close personal connection with the organization of the American Medical Association and the Congress.

There can thus be no doubt as to the sentiments of the profession. It is impossible that this sentiment should be changed by the mere fact that Drs. Cole and Shoemaker have been so completely effaced. This was a sop to the Philadelphia Cerberus; but it was a mean act and will win no support to the Committee.

News of the Week.

THE NEXT MEETING OF THE AMERICAN GYNECOLOGICAL SOCIETY.—The American Gynecological Society will hold its Tenth Annual Meeting at the Columbian University, in Washington, on Tuesday, Wednesday, and Thursday, September 22, 23, and 24, 1885. Among the papers announced to be read are the following: "The Natural Hygiene of Child-bearing Life," by Dr. S. C. Busey, of Washington; "Remarks on the Use of Tarnier's Forceps," by Dr. Ellwood Wilson, of Philadelphia; "Facial Paralysis in the Infant from the Use of the Obstetric Forceps," by Dr. T. Parvin, of Philadelphia; "The Genu-pectoral Posture in the Prolonged Nausea and Vomiting of Pregnancy, with Cases," by Dr. H. F. Campbell, of Augusta, Ga.; "On Two Rare Cases in Abdominal Surgery" (the President's Address), by Dr. W. T. Howard, of Baltimore; "The Care of the Perineum during Labor," by Dr. T. A. Reamy, of Cincinnati; "Report of a Case of Cæsarean Operation," by Dr. E. W. Jenks, of Detroit; "Puerperal Diphtheria," by Dr. H. J. Garrigues, of New York; "A Modification of Emmet's Cervix Operation in Certain Cases, with a Case," by Dr. R. S. Sutton, of Pittsburg; "Inflammation of the Parotid Glands after Ovariotomy," by Dr. William Goodell, of Philadelphia; "A Study of an Unusual Type of Puerperal Fever," by Dr. Fordyce Barker, of New York; "Peristalsis of the Genital Tract," by Dr. J. R. Chadwick, of Boston; "Four Cases of Oöphorectomy, with Remarks," by Dr. Joseph Taber Johnson, of Washington. Members of the profession are cordially invited to attend the meeting.

AN INTERNATIONAL PHARMACEUTICAL CONGRESS was held at Antwerp recently. The proceedings were opened by the Minister of Foreign Affairs, who in his address dwelt on the importance of the questions before the Congress to the well-being of the people. The following are the questions down for discussion: 1. Examination of the project of an international pharmacopœia, elaborated by the committee appointed at the last Congress in London. 2. Pharmaceutical instruction. What

instruction ought to be acquired previously to pharmaceutical studies? Pharmaceutical scientific studies. Professional applications. 3. Adulterations of human food, legislation, administrative service, etc. 4. Drinking water. The characteristics of potable water. What are, in the present state of science, the best practical procedures to be recommended for recognizing these characteristics?

The New York Post-graduate Medical School opened its regular session on September 12th. We learn that it already has an excellent class, and that there are the best prospects for a large attendance and active work. The school has spent a thousand dollars in fitting up its hospital, and much work has been done in preparing and equipping thoroughly the different departments.

A New Medical College is to be established at Los Angelos, in Southern California. The peculiarly great need of having one, or perhaps two medical colleges in Southern California has been long apparent.

British Comment on the International Congress.—The controversy in regard to the Washington meeting of the International Medical Congress in 1887 has entered on a new phase, by the publication in America of letters from Sir James Paget and Sir W. MacCormac, in both of which the writers expressly declare themselves in favor of the Congress meeting elsewhere than in Washington, unless an early modification of the existing state of things is brought about. Sir James Paget addressed his letter to Dr. Minis Hays, and, as the immediate predecessor in the presidency of the Congress of the lamented Professor Panum, his observations are likely to be received, even by the unfamiliar crowd of office-bearers at present nominated to posts in the next Congress, with attention, if not with respect. Sir James says decisively, "certainly it was not supposed that the Congress would be regulated, with any degree of exclusiveness, by the members of a Medical Association, however numerous; and I think it quite as certain that, if this had been thought possible, the proposal that the next meeting should be held in the United States would not have been adopted." Sir James farther expresses his belief, that without the support of the eminent men who now hold aloof from the Congress the meeting cannot be a success; and, though the proposition is too self-evident to need enforcing, it is perhaps as well that so high an authority should have thus spoken. A meeting is to be held this month by the innovating section of the American Association, and it is to be hoped it may be sufficiently impressed with the mischief it has already done to feel satisfied with the notoriety accruing from it, and agree to retire into that obscurity which is eminently becoming to its members, and out of which they have, this time at any rate, most unwisely emerged.—*Medical Press and Circular.*

Small-pox now prevails at Montreal, London, Paris, Bordeaux, Venice, Trieste, St. Petersburg, Warsaw, and Japan. A few cases have appeared in this city, and in several places in New England. The State Board of Health is making arrangements to furnish vaccine virus for the purpose of vaccinating persons all along the Canadian border of this State.

Cheap Medical Services.—A club of 4,800 members, in Berlin, recently advertised for six medical officers to attend them at a salary of $375 per annum. This would make the contribution from each member of the club about 75 cents a year for medical attendance. More than 400 doctors applied for the places.

The Work of the Summer Corps of Visiting Physicians.—The summer corps of visiting physicians visited this year 61,815 families, living in 15,832 tenements, and prescribed for 2,409 sick persons. The people were found to be in an unusually healthy condition, and the tenements were in better shape than usual.

Cholera in Japan.—Up to July 1st, there had been only sixteen cases of cholera in Japan. Recent reports show that the disease has become more active, and at one sea-port, Nagasaki, there were, between August 24th and September 1st, 300 cases. With both cholera and small-pox actively prevalent, Japan becomes a country to be carefully watched by our health officials.

The Cholera in Spain, France, and Italy continues to decrease in activity. Still, on September 14th, there were 1,075 new cases and 371 deaths reported. The disease has about disappeared from Toulon and Marseilles. But in little towns near those cities the mortality is even greater, in proportion to the number of inhabitants, than it has been at any time this year within the city lines. The disease is spreading in Italy. Rome has established quarantine against Sicily, in whose largest city, Palermo, the plague seems to have become fixed.

The Surgeon-General of the Marine Hospital Service.—There are several Republican Chiefs of Bureaus in the Treasury Department who have not yet been removed. Among them is Dr. J. B. Hamilton, Supervising Surgeon-General of the Marine Hospital Service. There is much talk at present concerning his place. Dr. Hamilton is reported, like his predecessor, Dr. Woodworth, to have the warm support of Senator Logan. There are several candidates for his position, all of them it appears from the West—Indiana having two, Kentucky, Michigan, and Illinois each one. Vice-President Hendricks is said to be supporting the claims of a Dr. Matthews, of Louisvile, while Messrs. McDonald and English are working for Dr. Walling, a physician and ex-druggist of Indianapolis, and son-in-law of Mr. English. Among the candidates named we hear of no worthy successor to Dr. Hamilton. The place, if made vacant, ought to be filled by some gentleman familiar with the Service, and having some professional standing. As an executive officer Dr. Hamilton has not been surpassed, and he has vastly improved the discipline and efficiency of the Service. A mistaken ambition to be more than the head of his Bureau has estranged the support of many members of his profession. This is the sole complaint that can be made against him.

The Methods of the American Ambulance Service, suspension harness and all, are warmly praised in Liverpool, where they have been in use for over a year. The record of the Northern Hospital gives the average time from the call to the departure of an ambulance at two minutes and fourteen seconds by day, and four minutes by night.

Advertising Medical Colleges in the Daily Papers.—Our attention has been called to the advertisement of a Colorado medical college in the Denver *Tribune-Republican*, also to that of a Chicago medical college in the *Leavenworth Times*. It is not generally considered proper or in good taste for medical colleges to advertise in purely secular papers. We regret that the practice seems to be endorsed by the esteemed and venerable Dr. N. S. Davis, Dean of the Chicago College referred to. As Partridge would say: *Nemo omnibus horis sapit.*

Small-pox in Japan.—Reports furnished us by the National Board of Health show that during the first six months of this year there occurred 4,472 cases of small-pox in Japan, with 1,191 deaths. There is need of extra precautions to prevent the introduction of this disease into our Western ports.

Mortality from the Cholera in Spain.—From March 4 to August 5, 1885, the National Board of Health reports 103,608 cases of cholera occurring in Spain, with 43,551 deaths, giving a mortality ratio of about forty-two per cent.

Dr. Hiram H. James, of Rahway, N. J., died at Saratoga, where he was being treated for liver affection, on September 11th. He was a graduate of the Jefferson Medical College, of Philadelphia, and was forty-six years of age.

Death of Dr. Guy, of London.—A cable despatch announces the death of Dr. William Augustus Guy, of London, at the age of seventy-five. He was educated at Christ's Hospital and Guy's Hospital, and at Cambridge, graduating in medicine in 1837. In 1838 Dr. Guy was appointed to the Chair of Forensic Medicine in King's College, London, with which department of medical science his name has been mainly associated. Dr. Guy wrote a series of essays on the Pulse and Respiration; on Statistics and the Numerical method, and on Health, Disease, Crime, and Vagrancy. These essays appeared in "Guy's Hospital Reports," the *Journal of the Statistical Society*, and in *Fraser's Magazine*. He also wrote "Principles of Forensic Medicine" and "Public Health." He was editor of Hooper's "Physician's Vade-mecum," of Walker's "Original," and of the "Evils of England." He wrote several tracts on social science questions and on the Eastern question, his signature, "A London Physician," being well known. Dr. Guy has devoted considerable time to sanitary reforms and other matters of public interest.

Dr. Francis D. Cunningham, of Richmond, Va., died on September 9th, at the age of forty-nine. Dr. Cunningham was born in Goochland County, Va. He graduated from the Medical College of Virginia in 1857, and afterward continued his professional studies in London and Paris. In 1870 he succeeded to his father's practice, which his own reputation as an ophthalmic surgeon had materially increased. Dr. Cunningham was a member of the Richmond Academy of Medicine, of which he was President in 1872; of the Virginia State Medical Society, of which he was President in 1875; of the American Medical Association, and of the American Public Health Association. He served as Professor of Anatomy in the Medical College of Virginia from 1867 to the time of his death. During the rebellion he was a surgeon in the Confederate Army, and in 1862 and 1863 he was Medical Director of the Trans-Mississippi Department.

Illness of Dr. E. G. Janeway.—We greatly regret to learn of the serious illness with pneumonia of Dr. Janeway. He is at Seabright, N. J.

A Doctor Assassinated.—Dr. Thomas Waugh, a physician of Chicago, Ill., was fatally shot on September 12th, while returning from a late visit to a patient. The assailant is said to have been a jealous husband.

Bismarck and his Physician.—It is certain that Bismarck's physician, though a charlatan, is no fool. It is related that when first presented the Prince was sick, and peevishly declined to answer questions. "As you like," said the doctor, "then send for a veterinary surgeon, as such practitioners treat their patients without asking them any questions." The Chancellor was captured.

A Successful Doctor.—A native of Madagascar who studied medicine in Edinburgh and returned home, now has seventy young men studying under him, and a large class of women whom he is training for nurses. He is in great favor with his Queen, and is about to marry the Prime Minister's daughter.

Memoirs of a Great Surgeon.—We learn from the *Allgemeine Wiener Medizinische Wochenschrift* that the late Russian surgeon, Professor Pirogoff, left an autobiography. Portions of this have already been translated from the Russian by Dr. Th. Bergmann, and have appeared in the journal referred to. The history of Pirogoff's early struggles is extremely interesting, and we should be glad to see the work made accessible to American readers.

California. — *The Pacific Medical and Surgical Journal* appears in a new and tasteful dress. We learn from its leading editorial that more serious efforts are apparently being made to enforce the medical registration laws and put down quacks.

Southern Surgery.—Our Southern brethren make good surgeons as well as physicians. We are glad to learn that Dr. Robert Battey, of Rome, Ga., has succeeded with his new hospital, and that since January last he has performed ovariotomy nearly every week, so far without losing a case.

Ozone as a Cause of Pneumonia.—Mr. Daniel Draper, Director of the Central Park Meteorological Observatory, has issued a circular in which he presents a number of statistics, showing apparently some relation between the prevalence of ozone in the atmosphere and the prevalence of pneumonia. To illustrate his observations, Mr. Draper takes the figures from January to May inclusive, for eight years. In 1878, during these months, there were 1,304 deaths from pneumonia, and the ozone percentage was 9.50 on 73 days. In 1882 the death-rate had increased to 2,056, and the ozone to 16.19 on 86 days. In 1884 the death-rate decreased to 1,608, and the ozone to 6.45 on 48 days. This year the death-rate increased to 2,308, and the ozone also increased to 13.26 on 87 days. The figures for 1882 and 1883 are

not quite so convincing. In the former the death-rate was 2,056, and in the latter 2,061. Yet in 1882 the ozone record was 16.19 for 86 days, and in 1883 12.73 for 85 days. The death-rates were about equal, though there was a difference of nearly twenty-five per cent. in the ozone ratings. Mr. Draper says, however, that he compared thousands of observations from the barometer, wet and dry thermometers, hygrometer, anemometers, and pluviometer with the mortuary statistics, and could find no continuous connection between these observations and the prevalence of pneumonia. It was only "when ozone was taken into consideration that there was found to be a very close connection between its observations and the death-rate from this disease." It has been very positively established by numerous observations that pneumonia prevails most at seasons when there are sharp variations in temperature, as, for example, in the Spring. We doubt very much if a case can be made out for ozone.

"The Courtesy of London Surgeons is phenomenal," writes Dr. Gay, in the *Buffalo Medical and Surgical Journal*. "I have never seen anything equal it, and have much admiration for it, and trust I have imbibed some of the spirit of it. At all events, I shall return home with the firm resolve that all strangers who may chance to come among us shall receive all the attention and courtesy that I may have in my power to extend to them."

New Medical Journal.—The *Quarterly Bulletin of the Clinical Society of the New York Post-Graduate Medical School and Hospital* is the title of a new medical periodical, edited by Drs. Seneca D. Powell, Thomas E. Satterthwaite, W. Oliver Moore, Charles Henry Brown, and Samuel Lloyd. It contains the proceedings of the Clinical Society of the School, and a number of original articles, college and hospital notes, etc. It is well edited and printed.

Experiments with the Microbe of Typhoid Fever.—At a recent meeting of the Academy of Sciences M. Tayon reported that he had inoculated himself and several of his friends with the microbe of typhoid fever. The general symptoms produced were insomnia, anorexia, pinched countenance, and liquid stools. There were also some local symptoms. A second inoculation, practised after complete re-establishment, produced no effect. No comment was made, but it was left to the Academy to form its own conclusions.

Good News for Pregnant Women.—Mr. John Bland, says *The Lancet*, has been letting his mind dwell on the case of women who have the misfortune to have to bear children in cold or temperate climates, as compared with their luckier sisters who have to discharge the same duty in the South of Europe or in Africa. He assumes that much of the difference is due to the mere difference of climate, the warm climate relaxing the tissues, and *vice versâ*. Upon this basis he has constructed a box with a heating apparatus, in which he proposes to place the lower part of the woman in labor. The heat of this box, he thinks, will bring the woman, at least in the lower part of the body, to the advantageous position of her more southern sisters. Again, it appears that a lady at the last Exhibition in Paris, in the seventh or eighth month of pregnancy, went up in a captive balloon, and before they could descend accomplished the whole of labor, including the expulsion of the placenta. He attributes this, not to the fright of the lady, but to the diminution of atmospheric pressure. He has therefore included in his invention a provision for exhausting the box of air on the approach of a pain. The process of labour is to be watched through a window!

Meeting and Work of the Committee on Organization of the International Congress.—The above Committee met in New York City on September 3d. Twenty-eight members, including their proxies, were present out of the total forty-six. The resignation of Dr. L. A. Sayre was accepted, and Dr. Austin Flint, Jr., was appointed in his place. Rules for the government of the Congress were then adopted. These are essentially the same as those governing previous Congresses. Section I. provides that the Congress shall consist of members of the regular profession . . . . who shall have inscribed their names on the register and taken out tickets of admission. The list of officers of the Congress is as follows: President, Austin Flint, M.D., LL.D., New York. Vice-Presidents, W. O. Baldwin, M.D., Alabama; H. I. Bowditch, M.D., Massachusetts; William Brodie, M.D., Michigan; Henry F. Campbell, M.D., Georgia; W. W. Dawson, M.D., Ohio; R. Palmer Howard, M.D., Canada; E. M. Moore, M.D., New York; Tobias G. Richardson, M.D., Louisiana; Lewis A. Sayre, M.D., New York; J. M. Toner, M.D., District of Columbia; the President of the American Medical Association, the Surgeon-General of the United States Army, the Surgeon-General of the United States Navy, the Supervising Surgeon-General of the United States Marine Hospital Service. Secretary-General, Nathan S. Davis, M.D., LL.D., Illinois. Treasurer, E. S. F. Arnold, M.D., M.R.C.S., New York. Chairman of the Finance Committee, Frederick S. Dennis, M.D., M.R.C.S., New York. Executive Committee of the Congress, Austin Flint, M.D., LL.D., President of the Congress; Nathan S. Davis, M.D., LL.D., Secretary-General; E. S. F. Arnold, M.D., M.R.C.S., Treasurer; Frederick S. Dennis, M.D., M.R.C.S., Chairman of the Finance Committee. Presidents of the Sections, A. B. Arnold, M.D., General Medicine; William T. Briggs, M.D., General Surgery; Henry F. Smith, M.D., Military and Naval Surgery; DeLaskie Miller, M.D., Obstetrics; Robert Battey, M.D., Gynecology; F. H. Tirrell, M.D., Therapeutics and Materia Medica; William H. Pancoast, M.D., Anatomy; John C. Dalton, M.D., Physiology; E. O. Shakespeare, M.D., Pathology; J. Lewis Smith, M.D., Diseases of Children; A. W. Calhoun, M.D., Ophthalmology; S. J Jones, M.D., Otology and Laryngology; A. R. Robinson, M.D., Dermatology and Syphilis; Joseph Jones, M.D., Public and International Hygiene; Henry O. Marcy, M.D., Collective Investigation, Vital Statistics, and Climatology; John P. Gray, M.D., LL.D., Psychological Medicine; Jonathan Tafft, M.D., Dental and Oral Surgery. The other officers of the Sections were not appointed, but power to fill vacancies was left with the Executive Committee.

Therapeutical.—Experience is the mother of therapeutics; physiology is the mother-in-law.

Reports of Societies.

THE AMERICAN DERMATOLOGICAL ASSOCIATION.

Ninth Annual Meeting, held at the Indian Harbor Hotel, Greenwich, Conn., August 26, 27, 28, 1885.

WEDNESDAY, AUGUST 26TH — FIRST DAY — MORNING SESSION.

THE meeting was called to order by the President, DR. W. A. HARDAWAY, of St. Louis.

DR. J. E. GRAHAM, of Toronto, Can., reported

A CASE OF TUBERCULO-ULCERATIVE SYPHILIDE OF HEREDITARY ORIGIN.

The patient was a girl, twenty years of age. On the right arm, from the wrist to the elbow, there was little but cicatricial tissue. The skin of the forearm presents elevations and depressions, and in places is covered with thin scales. The hand is not involved, and the affection does not extend deeper than the subcutaneous areolar tissue. For three or four inches above the elbow the arm is atrophied and covered with cicatricial tissue. At the upper border of the cicatricial tissue, there is an ulcer three-fourths of an inch wide, which encircles the arm. Above this there is sound tissue. No nodules are present. The left clavicle presents about its middle a swelling and ulceration about the size of a silver dollar. This was the result of a blow. There is no copper-colored appearance. Investigation of the family history showed that the mother was apparently healthy. Three of the patient's sisters, all younger than herself, were healthy. The father died of pneumonia when the patient was a child. It was subsequently learned that he had also had syphilitic ulceration of the throat. The treatment consisted in the local application of a mild mercurial ointment and the internal use of bichloride of mercury and iodide of potassium. The condition steadily improved, and in the course of six or eight weeks the ulceration had healed. The patient at that time passed from observation.

The speaker referred to the difficulties of diagnosis in this case, as there was a complete absence of specific history, the facts in regard to the father not being learned for some time after the case had been under treatment. There was no history of any previous evidence of hereditary syphilis, but taking all the facts into consideration, the doctor thought that there could be no doubt as to the correctness of the diagnosis.

Photographs, showing the condition, were exhibited.

DR. R. W. TAYLOR, of New York, remarked that it is now generally conceded that syphilis can be communicated to the child without infection of the mother, and he believed that he had been the first in America to call attention to this fact. He had seen this a number of times. The doctor had stated that he could obtain no history of early manifestations of hereditary syphilis. This is not uncommon, but that there is usually some indication of specific taint, although this may be so slight as not to excite notice, or its exact import is not recognized.

DR. GREENOUGH, of Boston, said that within the past two months he had seen a woman who had lost three children in succession from hereditary syphilis, yet she was strong and apparently perfectly healthy, and has never shown any signs of syphilis. This woman has been under observation for six or seven years.

DR. L. A. DUHRING, of Philadelphia, said that the result of treatment in causing a rapid cure in the case described would certainly incline one to the opinion that this was a case of syphilitic disease.

DR. J. N. HYDE, of Chicago, stated that he had seen cases which had convinced him that, while it is not the rule, still occasionally syphilitic children are born where, so far as observation can be made, no evidence of syphilis in the mother can be detected. As far as the general health is concerned, the women are usually pallid and weak, although there may be no symptoms which can be ascribed to syphilis. He had never seen inherited syphilis manifesting itself for the first time in advanced years. The more he saw of syphilis, the more he was satisfied that in its origin, heredity does not amount to very much. The accidental cases of syphilis are very common. He had seen the initial lesion of syphilis on the head of the penis, where it was unquestionably due to inoculation from the finger of the surgeon in catheterization. There was no doubt that the case described was one of syphilitic trouble, and as Dr. Duhring has said, the result of treatment unquestionably pointed in that direction. There are no cases which yield so readily as old cases of untreated syphilis. As to pronouncing it a case of hereditary syphilis, his experience would not permit him to do so.

DR. W. A. HARDAWAY, of St. Louis, considered it unwise to base our diagnosis on the results of internal treatment. Because a case gets well under anti-syphilitic treatment it does not prove that the affection is specific in its nature. Local treatment is often all that is necessary.

The next paper was entitled

CLINICAL NOTES ON PSORIASIS,

by DR. F. B. GREENOUGH, of New York. The paper was founded on the records of 394 cases of psoriasis. This number occurred in about 15,000 cases of skin disease examined, and represented about two and one half per cent.; 205 cases occurred in males and 188 in females. Several tables of statistics were presented, showing when the cases first come under observation, and the age at which the attack was first observed. A large proportion of the cases were first attacked with psoriasis between the ages of ten and forty years. In 97 cases the speaker had been able to get reliable evidence in regard to the family history. In 31 cases psoriasis had existed in a near relative, but in 66 cases, the patients felt sure that the disease had existed in no other member of the family.

As regards locality affected, where there is much development it is almost constantly found about the elbows and knees, and more frequently on the extensor surfaces than on the flexor.

Well-marked cases are readily diagnosed, but in some cases there is considerable difficulty in making the diagnosis. It is most frequently confounded with some form of eruption resulting from constitutional syphilis. When psoriasis affects the scalp, its appearance is often similar to that of secondary syphilis. In psoriasis, however, the patch consists simply of epithelial cells, and there is no hyperæmia connected with it. In syphilitic eruption the crust will contain other elements than epithelial cells, and on removal of the crust spots of moisture will be detected. A characteristic symptom of psoriasis of the scalp is a band of hyperæmia, about three fourths of an inch wide, extending around the forehead contiguous to the hair. This is a point of value in the diagnosis between eczema capitis and psoriasis. In the former affection this band is wanting. Psoriasis is not accompanied with enlargement of the post-cervical glands, as is eczema. The diagnosis from favus is made by the age of the patient, the evidences of destruction of the hair-follicles in favus, and the microscopical examination. The speaker had never been able to satisfy himself that psoriasis of the scalp ever caused permanent loss of the hair.

On the general integument syphilides are most apt to resemble psoriasis. The regions on which the eruptions appear is important. The syphilides are apt to affect the flexor surfaces, while the psoriasis affects more commonly the extensor aspects. Psoriasis begins as a mi-

nute point of hyperæmia, which may last for several days. In macula syphilide a crop of macules appear within twenty-four or forty-eight hours. When the eruption fades there is in syphilis a decided pigmentary change. In squamous syphilis the epithelial scales differ from those of psoriasis. In some cases of psoriasis there is severe itching, leading to scratching of the skin, and as a result scabs and crusts make their appearance, but here the cause of the condition is readily recognized.

The amount of pruritus complained of in psoriasis varies, but it is rarely a prominent symptom, although in exceptional cases it is very severe. He had never seen any eruption on the hands or feet resembling psoriasis, with the exception of eczema, which was not syphilitic.

In regard to treatment, some cases do well, while others do not. There is no specific. What will benefit one case may make another worse. In my experience, tarry preparations, especially the oil of cade, have been most efficacious. Great comfort may be afforded by the use of emollients. Cod-liver oil is one of the best applications. Cod-liver oil and oil of cade (equal parts) is a common prescription. Chrysarobin is a powerful remedy, but has the disadvantage of destroying the clothing. On the face and scalp it is apt to produce dermatitis. The internal administration of arsenic in some cases is of benefit. Even after apparent recovery there is great danger of relapse.

Dr. L. A. Duhring said the reader of the paper, in referring to the diagnosis, did not allude to the difficulty sometimes experienced in diagnosing seborrhœa capitis from psoriasis. He had found considerable trouble in the diagnosis, particularly in young girls. In these cases the eruption was confined to the scalp.

Dr. A. R. Robinson, in the diagnosis of favus and psoriasis, did not agree with the author in one of his points of diagnosis. In the early stage you do not find moisture when the crust is removed. There is a shiny appearance. It is only in advanced stages that ulceration is present.

He agreed with the speaker that psoriasis always occurs in small spots, at first not covered with scales. He considered it primarily an affection of the rete. While it is true that psoriasis often disappears without producing pigmentation, yet there may be discoloration found on the lower extremities, particularly where there is a varicose condition of the veins. In some cases where there are only a few patches of psoriasis, limited to the lower extremities, it is often difficult to make the diagnosis, unless there is involvement of other parts of the body or you have the history. There are other cases of acute psoriasis which closely resemble acute eczema.

Dr. J. C. White, of Boston, agreed with the previous speakers in regard to the difficulty of diagnosing between psoriasis of the scalp and seborrhœa. In some cases the diagnosis cannot be made for months. In all parts of the body pigmentation may follow psoriasis, but never over large areas.

He called attention to one termination which he had seen in three cases, and that was a degeneration into epithelioma.

Dr. R. B. Morison, of Baltimore, had seen many cases of psoriasis, and could only recall one or two cases of psoriasis in the negro. In such cases there is a loss of pigment.

Dr. G. H. Fox, of New York, had been very successful in the treatment of psoriasis and its management; he adopted the teaching of the late Tilbury Fox, who laid stress on the point that in psoriasis the first thing to do is to lessen the congestion of the skin. This is done by restricting the diet, giving fruits and vegetables in the summer, and in the winter giving a carefully restricted diet. Tea, coffee, tobacco, and stimulants of all kinds are to be cut off. By so doing more will be accomplished than is obtained by using arsenic and local applications at the start. In regard to local remedies, he never used tar in the treatment of psoriasis. With the application of chrysarobin, made at the proper time, there is no necessity for the use of tar. Sometimes the drug did no good, but this was because the application was made when the patches of psoriasis were in a congested condition. If the acute congestion is lessened, chrysarobin will produce beneficial results.

Dr. C. Heitzman, of New York, said one of the most important points after making the diagnosis is to decide as to the acuteness or chronicity of the affection. If it is acute, local applications are to be avoided. If the case is chronic, chrysarobin may be used with advantage, at least temporarily. It is not a cure. Tar cannot be dispensed with. Chrysarobin remedies the disease for a time, but in a few months it returns. There is nothing like tar to prevent the recurrence. No mention had been made of pyrogallic acid, which does good in some cases.

Dr. W. A. Hardaway believed that in psoriasis we have a disease situated in the skin itself. It is frequently hereditary. The same sort of skin may be transmitted, just as a certain color of the hair, or of the eye, may be transmitted, and then any exciting cause may develop the psoriasis. Traumatism is frequently the exciting cause. Psoriasis sometimes follows eczema. It is not unlikely that in seborrhœa of the scalp there may be the development of psoriasis. Internal causes may produce it. He had seen the excessive use of oat-meal produce typical psoriasis. As a local application he believed that chrysarobin, with salicylic acid, was very useful in chronic cases. Arsenic is useful on account of its action on the skin. He had employed chrysarobin in liquor gutta-percha, and in gelatine paste. This treatment may be followed up by the application of sulphur ointment. In psoriasis of the scalp sulphur is quite an efficient remedy.

Dr. J. C. White, of Boston, reported

TWO CASES OF ANGIOMA PIGMENTOSUM ET ATROPHICUM.

The first patient was a young man, seventeen years of age, and a Russian Pole by birth. Freckles appeared on his face before he was two years of age. These increased in number until the age of six. When the telangiectasic condition first appeared was not noted. When seen the patient was well developed, and apparently in good health. He had, however, grown slowly, and was then no larger than a boy of twelve. The hair of the head was abundant and intensely black. The eyes were also black.

Present condition, melanosis. The forehead and lower portion of the face were of a dark-brown color, and on close inspection small spots of a darker color were seen. The whole trunk was as dark as the skin of a dark Spaniard. The scrotum was very black, and the penis and glans presented dark spots. The arms and hands were thickly spattered. The legs were also affected. On the right thigh there was one spot of dark color, covered with rather long hair. The mucous membrane of the mouth and pharynx was free from melanosis.

The atrophic condition: On the right side of the face occupying one-half the surface, was a sharply defined area of white cicatricial-looking skin. Similar areas were seen on the other cheek, forehead, and about the mouth. A few white spots were seen on other portions of the body. The sensibility of the affected areas was decidedly lessened.

Telangiectasis: Over parts of the face there were bright red spots, varying in size from a pin's head to a pea. They were most noticeable in the atrophied portions. Within the lids there were two angiomatous new-growths. Several vascular twigs were also seen on the face. A few red points were found on the general surface.

The second case was a brother of Case I., aged three years, born in New York. When eighteen months old little colored freckles were noticed on the face. Since then the condition has been developing. His hair was

dark brown, and his eyes black. The face was covered with numerous dark-brown freckles. The spots were so close together that at a little distance the skin had a uniform color, in some places the spots were slightly elevated. The backs of the hands were covered with dark-brown spots, elsewhere the skin was clear. There were no leucodermic spots, and no angiomatous condition.

From a study of these cases Dr. White concluded that in the beginning the development of the spots could not be distinguished from ordinary freckles. Gradually the spots multiplied until they involved a considerable portion of the skin. It was probable that several years might elapse without other manifestation of the disease. The telangiectasic condition was probably secondary. In the first case it was most developed in the atrophic portion. It was probable that in this case there would be hypertrophy of the epithelium, and final transformation into epithelioma. This had been the result in the thirty-three cases which had been reported.

WEDNESDAY, AUGUST 26TH—FIRST DAY—EVENING SESSION.

DR. J. N. HYDE, of Chicago, read a paper on

RELATIONS OF LUPUS VULGARIS TO TUBERCULOSIS.

The following clinical facts were cited in support of the view that lupus vulgaris was not the result, as had long been taught, of tuberculosis or other systemic diatheses, but was the product of a local infection by bacilli, entirely unassociated with any constitutional evidence of diathesis or predisposition: 1. The unimpeachable character of the family record in by far the larger number of cases of lupus vulgaris. 2. The fact that the disease is, in its inception, a disorder of the period of childhood, when, for the most part, the habits of the child are favorable to infection. 3. The several sites of predilection are those most favorable to such infection. 4. The failure of the disease to spread by inheritance. 5. The remarkable tendency of lupus vulgaris to cutaneous limitation.

DR. J. C. WHITE, of Boston, read a paper entitled

THE TREATMENT OF LUPUS BY PARASITICIDES.

The doctor reviewed briefly the evidence in favor of the parasitic nature of the affection. All previous plans of treatment which had proven most successful were those which would have the effect of destroying any parasite which might be present.

A number of cases were then reported, in which the local use of corrosive sublimate, in the strength of two grains to the ounce of water or unguent, had been used with beneficial results. The ointment was especially recommended. It had been rarely necessary to prolong treatment over two months. As regards the permanency of the cure, the author was unable to speak, as the experiments had been continued for only eighteen months.

DR. SHERWELL expressed his profound disbelief in the parasitic nature of the disease.

DR. WIGGLESWORTH suggested that the oleates might be more efficient than ointments, on account of their penetrating power.

The next paper was by DR. W. A. HARDAWAY, of St. Louis, on

THE TREATMENT OF PORT-WINE MARK BY ELECTROLYSIS.

In the treatment of this affection the object is to excite sufficient inflammation to cause occlusion of the vessels. Electrolysis seems to be the most convenient way of doing this. At first the speaker had used a bundle of needles, but now he employed only the single needle. It is important to allow a period of some weeks to elapse between the applications. The histories of three cases were given in which this method had been employed.

DR. WIGGLESWORTH had seen good results from cutting the vessels in two places and using a preparation of iron, thus closing up the dilated vessels.

DR. FOX thought that better results could be obtained by electrolysis than by other measures, but it did not remove the trouble entirely.

DR. DENSLOW had recently seen a case of port-wine mark on the labia majora of an infant. This had ulcerated when the child was brought to him. As a temporary measure he applied liquor gutta-percha. In two days, without other treatment, the whole mark sloughed out, leaving nothing but a simple ulcer, which completely healed in the course of three weeks.

DR. HARDAWAY said that the advantage of the electrolysis was that it was manageable. A practical point might be referred to, and that was, if after the operation the part should be frequently mopped with hot water the inflammatory disturbance would be greatly lessened.

REMARKS ON A MOOT POINT IN THE ETIOLOGY OF PSORIASIS

was the title of a paper by DR. S. SHERWELL, of Brooklyn. The speaker had been struck by the great diversity of opinion in regard to the general health of those affected with psoriasis, and in order to arrive at something like a consensus of opinion on the subject, he had referred to the writings of most of the authorities on dermatological matters. Brief extracts from various writers were then given. The evidence thus obtained strengthened the doctor's opinion that the patients with psoriasis were generally in good health. He thought that the theory of Piffard, who believes that the rheumatic diathesis is a great exciting cause of psoriasis was the most rational theory that had been advanced.

THURSDAY, AUGUST 27TH—SECOND DAY—MORNING SESSION.

At the business meeting officers were elected as follows:

President—Dr. E. Wigglesworth, of Boston, Mass.

Vice-Presidents—Dr. I. E. Atkinson, of Baltimore, Md., and Dr. A. R. Robinson, of New York, N. Y.

Secretary—Dr. G. H. Tilden, of Boston, Mass.

Treasurer—Dr. H. W. Stelwagon, of Philadelphia, Pa.

Dr. E. B. Bronson, of New York, was elected to membership.

The next meeting will be held, beginning the last Wednesday of August, 1886, at Indian Harbor Hotel, Greenwich, Ct.

DR. G. H. FOX gave a brief description of two cases of

DYSIDROSIS.

The first patient, for want of a better term, he classed under this heading. The patient was twenty-nine years of age, and had always perspired freely. Four years ago the eruption began on the palms of the hand and had persisted. The soles of the feet had also been affected at one time. The skin of the hands was decidedly thick and had a dark hue, and was dotted with numerous elevations of epidermis, averaging in size that of a hemp-seed. The patient had never seen any moisture in connection with this. There had been no itching. The skin never peeled off. Puncture with a needle revealed no serum or fluid of any kind.

The second case was that of a woman, aged forty-five, a cook, whose general health was good. The present trouble began five years ago. The eruption is on the face and consists of numerous large and small vesicles containing clear fluid.

DR. A. R. ROBINSON, of New York, read a paper on

MYCOLOGICAL STUDIES IN TINEA FAVOSA AND TINEA TRICHOPHYTINA.

The speaker prefaced his paper with a few general remarks. The epidermis of different individuals differed in susceptibility to these parasites. Children were more apt to suffer with tinea trichophytina and favus, while adults more frequently presented tinea versicolor. All

children are not equally susceptible. In many cases of parasitic disease there is impaired vitality previous to the development of the affection.

The speaker then gave an account of his investigations to determine the exact anatomical seat of the parasitic diseases in question, and to determine the changes which they produced in surrounding tissues. The conclusion was that in favus the rete is not affected until the later stages, when ulceration had made its appearance. The parasite confines itself more particularly to the corneous layer. The parasite of tinea trichophytina in some cases passes down into the rete, while in others it does not.

A number of sections were shown under the microscope, which illustrated the points brought out in the paper.

Dr. White did not agree with the speaker in the importance of depressed general health as a factor in the production of these diseases. He had never seen any necessity for internal treatment in these cases.

Dr. Piffard agreed with Dr. Robinson that there was a relation between the condition of the general system and the rapidity of development and rapidity of cure.

Dr. Duhring had always held the view that a particular condition of the epidermis was necessary for the growth of the fungus. The majority of cases of obstinate ringworm that he had seen had been in individuals in poor health, but there were exceptions to this rule. What this peculiar condition of the skin was had not been determined.

Dr. Denslow had recently seen a large number of cases of ringworm of the head and beard, but all the patients were well-developed, muscular subjects. These were cured without internal treatment.

The next paper was,

ON THE STRUCTURE OF THE DERMA AND THE DEVELOPMENT OF ELASTIC TISSUE IN IT,

by Dr. C. Heitzman, of New York. The essayist drew attention to the fact that Professor Stricker, of Vienna, the acknowledged best microscopist of Europe, has now accepted his views concerning the life of basis-substance. Dr. Gartner (who was present at the meeting), Stricker's assistant, has brought from Europe an electric picture microscope, by means of which these newly discovered facts can easily be demonstrated to a large audience upon a screen. There are three varieties of basis structure, differing from each other in their chemical constituents, viz., the glue-yielding basis-substance proper, producing the spindles within the bundles of so-called fibrous connective-tissue; the cement-substance between the spindles; and the elastic-substance developing along the edge of the bundles in advancing age and in some tumors. All three varieties are traversed by a delicate reticulum of living matter in connection with the protoplasmic cords that fill the interstices between the bundles in the shape of a comparatively coarse reticulum. Thus it becomes intelligible that in morbid processes not only the protoplasm but also the basis-substance participates in an active manner. After the liquefaction of the solid fields of glue-yielding basis-substance, the bundles directly are transformed into inflammatory corpuscles, from which starts every physiological and pathological new-formation.

Dr. W. A. Hardaway described a case of multiple myomata of the skin, accompanied with severe pain. The patient was thirty-six years of age, married, with healthy children, and good family history. Never had syphilis. Present trouble began a year ago. Changes in weather produced pains in the parts which have since become affected. To relieve these, firm pressure was made with the hand. Between the paroxysms pain was not produced by pressure. Later the lesions presented themselves.

Present condition: A strong hearty man, a pedler by occupation. The pains still persist, recurring at intervals of one night to a week. Each attack lasts two or three minutes and does not return the same night. The growth is situated on the right side of the back, in the mid-dorsal region, and the course of the growths is obliquely outward. There are one or two of the elevations on the left side. Three of the growths are as large as peas, others are small. The epidermis is not abnormal. On passing the hand over these growths there is no hyperæsthesia, but on deep pressure in the neighborhood of the larger masses the patient sinks moaning to the floor. One of the larger growths was removed and microscopical examination showed it to be composed of smooth muscular fibre.

From a clinical standpoint the case bears a close relation to the cases of neuroma which have been reported. The speaker concluded that certain new-growths in the skin, accompanied with severe pain, may be widely different histological structures. We are not justified in assuming that a painful tumor of the skin is a neuroma or fibro-neuroma simply from its clinical history, without a microscopical examination.

Dr. R. S. Morrison, of Baltimore, Md., reported

AN UNUSUAL CASE OF TYLOSIS OF THE HANDS.

The patient was a negro, aged thirty-two, muscular, well developed, and apparently healthy. By occupation he was a fireman of a steamer, and had occupied this position for ten years, shovelling coal with the right hand grasping the upper portion of the shovel, and the left hand sliding up and down the handle. Two fingers of the left hand are worn off to the second joint, while the other two are going in the same way, the nails having nearly disappeared. On several occasions he has drawn pieces of bone from the fingers. There has been no pain at all connected with the affection. On this hand there are some large blisters, underneath which there are red granulating surfaces, which are painless. There is no history nor evidence of syphilis. Specific treatment has been used without effect. The man obstinately refuses to give up his work, so that little could be done in the way of treatment.

The speaker was led to consider it a strictly local affection from the fact that the hand which was most exposed to rubbing and to the heat of the furnace was the one most affected.

Dr. Duhring was inclined to consider the callosities a secondary condition. The occupation probably had something to do with the aggravation of the disease, but if the occupation had been different there would probably have been a similar change. He would regard it as dependent on some deep change in connection with the nerves, similar to what occurs in perforating ulcer of the foot.

Dr. Morrison could not admit that it was an affection of the nerves in the first place. It might be that the continued congestion of the skin, dependent on his occupation, produced changes in the nerves or other parts, which culminated in this affection. In referring to the literature of the subject, he had found similar cases attributed to mechanical irritation.

THURSDAY, AUGUST 27TH—SECOND DAY—EVENING SESSION.

Dr. L. A. Duhring, of Philadelphia, read a paper on

THE RELATION OF HERPES GESTATIONIS AND CERTAIN OTHER FORMS OF DISEASE TO DERMATITIS HERPETIFORMIS.

Dr. Fox exhibited a photograph of a case which might be mistaken for dermatitis herpetiformis, namely, erythema multiformis. This disease should be placed in strong contrast with dermatitis herpetiformis.

MYCOSIS FONGOÏDE,

was the title of a paper by Dr. G. H. Tilden, of Boston, Mass.

The speaker described the case of a man, aged twenty-eight. When he came under observation, three years be-

fore, several red desquamating spots had been observed on the elbows. Several months later erythematous spots, accompanied with pruritus, were noted. These lesions retained a dry, scaly character. There were no vesicles or pustules. At the end of a year several red nodules appeared on the face and throat; these, however, disappeared. Later a small papule appeared on the right thigh, and increased in size. From this there exuded a thin fluid. This was followed by the development in many parts of the body, particularly the axillæ, groins, and neck, of similar lesions, in some cases reaching the size of a hen's-egg. After a time there was superficial erosion of some of the tumors, but these excoriated tumors remained firm in consistence. But some of the masses which were covered with epidermis were soft, but there was no evidence of the formation of pus. There was also indolent enlargement of the lymphatic glands. The general health continued good. The patient passed from observation, and died at the end of three years and a half.

The report of the microscopist who examined the tumors was read. His opinion was that the growths consisted of the formation of lymph-tissue in corium.

Reference was then made to the literature of the subject, and the various cases, some thirty in number, which had been reported, were given, and the symptoms and course of the disease was described. Sections of the growth were also presented for examination.

Dr. White said that this patient was under his care during the last stages of the disease, and he presented the changes which have been described. Some of the larger growths disappeared. During the last months of his life the man was taking arsenic. Death resulted from the occurrence of diarrhœa.

Dr. Fox said one or two similar cases had been seen in New York. Should one come under his care, he should try the effect of Calamooga-oil. Judging from its effects in other cases it should be useful.

Dr. Heitzman remarked that the description of the microscopic appearance was that of a lympho-sarcoma, and the examination of the specimen confirmed him in the view that this was a case of lympho-sarcoma.

Dr. Sherwell, to show the amount of involution that may take place, reported a case of melano-sarcoma under his care. The man was treated with arsenic, mercurials, etc. After six months' treatment the tumors had almost entirely disappeared. There was not the slightest evidence of syphilis.

Dr. Fox had seen Calamooga-oil used in a case of leprosy. There was now not a trace of leprosy except the contraction of the fingers, which is, however, a secondary condition. It had failed in many cases, but there was sufficient to justify a trial of it in the chronic inflammatory affections referred to.

Dr. L. N. Denslow, of St. Paul, Minn., read a paper on

URETHRAL IRRITATION IN THE MALE AS A CAUSE OF CERTAIN NEUROSES AND OF ACNE.

He prefaced his remarks by a brief review of the cases of contracted meatus reported by Dr. Otis. He then gave an account of a number of cases coming under his observation in which there were reflex conditions associated with conditions of the urethra, such as contracted meatus, stricture, and excessive sensitiveness of the prostatic urethra. In these cases removal of the urethral trouble produced an alleviation or cure of the affection, to which attention had been directed. He also reported four cases of acne, in which the same treatment had been followed by marked improvement or cure of the skin disease. In some of the cases ergotin was also employed. The speaker said that he simply reported the cases as so many observed facts, and did not express any theory. He would keep the cases under observation, and at a subsequent meeting give a further report.

Dr. Hyde said many of these cases with urethral trouble associated with acne were patients who probably had been taking for some time balsamic preparations, and as a result they had the development of acne. He would suggest to Dr. Denslow, that he take this point into consideration.

Dr. Denslow said in all the cases reported the acne had existed since puberty. The patients were not hypochondriacs, and they were not masturbators. He was satisfied that no drugs had been used in any of them.

Friday, August 28th—Third Day—Morning Session.

Dr. C. Heitzman, of New York, read a paper entitled

REMARKS ON ELECTROLYSIS AND OTHER PRACTICAL TOPICS.

The reader spoke very highly of electrolytic depilation. For this purpose he uses the Leclanché battery. Six cells of this battery have the advantage of steadiness, lack of pain, and lack of reaction when applied to the face of the patient. He employs a needle devised by Leiter, of Vienna, which permits the depth to which the needle penetrates to be measured. He has had good results from electrolytic destruction of dilated blood-vessels in the face, less satisfactory results in the treatment of port-wine marks, where a permanent cure is only exceptionally attainable. Sodium ethyl is highly recommended by some for the destruction of angioma of the face, but it is in no way superior to nitric acid.

The speaker maintained, after observing two hundred cases of falling off of the hair, caused by seborrhœa, that the method he recommended in 1876 gave fair results. This is the application of a ten or twenty per cent. ointment of crude oleum rusci in vaseline and paraffine.

For the removal of freckles, the doctor used an ointment recommended to him by Wertheim, of Vienna. The preparation is as follows:

℞. Hydrarg. ammon. muriat.. 3.75 grammes.
Magist. bismuthi ..... 3.5 "
Ungt. glycerina ..... 30.0 "
M.

This is to be applied in a thin layer, every other night and in four or six weeks the result is highly satisfactory. As to the permanency of the cure the doctor was unable to state.

In regard to the reappearance of hair after removal by electrolysis, the speaker considered it to be due to the growth of the fine hairs, which was increased by the transference to them of the nutrition which should have gone to the hairs removed.

Dr. Hyde thought that Dr. Heitzman had touched upon the important point in the removal of hair by electrolysis. The question was not what will the result be at present, but what will it be in the future. The electrolysis produces a hyperæmia which tends to stimulate the growth of the remaining hair.

Dr. Fox had used nitric acid in the treatment of angioma, making the application in the form of small dots one-fourth to one-half an inch apart, with great advantage. In one case in which a nævus occupied half the body, he used this treatment with much success. He did not think that the removal of hairs increased the growth of others. In one case, that of a young woman with a strong beard, he removed, by actual count, eight thousand hairs. This process required two or three years. Since then it had been necessary to remove only a few dozen hairs.

Dr. Robinson had used a similar ointment for the removal of freckles, but its effect was only temporary.

Dr. Wigglesworth remarked that for the past fifteen years he had used the following ointment, which was almost identical with that mentioned by Dr. Heitzman:

℞. Hydrarg. ammon ..... 10 parts.
Bismuthi subnitratis ..... 10 "
Vaseline ..... 100 "
M.

Dr. Hardaway had performed the operation of electrolysis for ten or twelve years. He employed the iridoplatinum needle, which could be bent and was not likely to pass through the follicle-wall. The moment the follicle was entered there was escape of serum. One case, that of a woman with a heavy black beard, had been entirely relieved. Electrolysis with a fine needle affords a method of getting rid of freckles. The plan is to dot the needle over the surface covered by the freckles.

Dr. Heitzman said that the percentage of recurring hairs is greater in some situations than in others. In the submaxillary region it is greatest.

Dr. R. W. Taylor, of New York, read a paper

ON SYPHILITIC REINFECTION.

The speaker first referred to the literature of the subject, and gave a brief review of the authentic cases on record, giving the names of the reporters. The number of cases previously reported number between thirty and forty. To these the speaker added the histories of three more. A fourth case had been observed by him, but as the complete history was not prepared it was not given.

Case I. was a barkeeper, twenty-five years of age. Was first seen 1868, suffering from gonorrhœa. Three years previously had had indolent enlargement of the lymphatic glands in the groins. Examination showed the presence of lymphatic enlargement in certain regions. Inquiry into the history showed the existence of a chancre three years before, which had been slow in healing. About two months later, he became sick and suffered with a roseollar eruption, sore throat, falling off of the hair, and rheumatic pains, worse at night. Under treatment he improved, but afterward exhibited a papular eruption. He was then seen by Dr. Van Buren, who pronounced the case one of syphilis, and ordered mercurial treatment. He recovered after two years, but of his own accord continued the treatment two years longer. He then remained well until the attack of gonorrhœa. In February, 1870, he again appeared presenting a typical indurated chancre on the cutaneous aspect of the pubes. It presented every evidence of a primary infection. Later a papular syphilide appeared, over the body. There were several mucous patches on the pillars of the fauces, and the throat was red and swollen. The joints soon became the seat of nocturnal pains. The patient also presented a form of syphilitic epididymitis. Under mercurial treatment there was some improvement, but a year later there were some tertiary manifestations. By 1874 he seemed very well. During the next three years there were no evidences of syphilis, but he continued the mixed treatment. He was again seen in the fall of 1882, when it was learned that his good health had continued, and that he was the father of a healthy child. The child was examined and no evidence of hereditary syphilis detected.

Case II. had in June, 1873, a typical indurated chancre, followed by distinct secondary symptoms, which disappeared under treatment. He then passed from observation. In February, 1874, he presented several ulcero-tubercular lesions on the outer aspect of the forearm. He then remained under treatment six months. In January, 1875, he had spots of thickening of the periosteum of both tibia. He was again treated with benefit. In June, 1876, there was a typical indurated nodule on the prepuce, from which indurated lymphatics extended to the inguinal lymphatic glands. The incubation of this sore had been about twenty days. This was followed by malaise, sore throat, swelling of the post-cervical and epitrochlear glands. Over the body and arms there was a fine mottling of light pink color. The patient then went to Europe and was not seen until March, 1885, when it was learned that the symptoms had been well marked, and that he had been under treatment for them with several Continental physicians.

Case III., aged forty-one, had had a typical indurated chancre in 1874. There had been inguinal adenitis, followed by roseola, falling off of the hair, and later by severe iritis of the right side. He was treated with mercury. In February, 1882, he returned with a typical hard chancre. In April he became sick, had rheumatic pains and a mixed eruption of erythematous and papular syphilide. In May, inflammation of the iris of the right eye again appeared. In 1883 he had a late secondary rash.

These cases were reported with the object of throwing some light upon the natural history of second infections of syphilis. In all these cases relapsing indurations were carefully excluded.

Dr. W. H. Stelwagon, of Philadelphia, reported some

OBSERVATIONS ON THE OLEATES.

Of all the oleates, those of mercury, zinc, bismuth, and lead had a place in the treatment of diseases of the skin, and in view of their costliness, the seeming unavoidable frequency of badly made preparations, the disagreeable oleic acid odor, and the irritation so frequently observed following their use, it was probable that of these four the mercuric oleate alone promised to retain a permanent value. This last was especially valuable in ringworm of the scalp, but for inunctions in the treatment of syphilis it was of doubtful utility, as it was questionable whether it was absorbed. Oleate of copper, which had been so highly recommended for ringworm of the scalp, was not comparable in that affection to oleate of mercury, or to tar and sulphur preparations.

Dr. Wigglesworth had practically renounced all oleates except the oleates of zinc, lead, and mercury, as parasiticides.

Dr. Duhring's experience with these preparations was in accord with that of the reader of the paper. He had employed the oleate of copper in varying strengths in thirty or forty cases of ringworm, but it seemed to exert no influence whatever. These were, however, obstinate cases. As to its efficiency in acuter forms of ringworm he was not prepared to speak.

Dr. Heitzman had tried the oleate of copper in chronic cases of ringworm without any result, but in the acute cases it cured after a time. It was not as efficient, however, as the preparation recommended by Dr. Taylor, that is, four grains of bichloride of mercury to the ounce of tincture of myrrh.

Dr. Fox remarked that it had been claimed that the oleic acid and animal oils were better absorbed than these other preparations. As a matter of experience, he had found that vaseline made a better base for the majority of ointments than the animal oils. Vaseline was a most soothing application to the skin.

Dr. L. N. Denslow, of St. Paul, Minn., reported

A CASE OF SYPHILITIC APHASIA AND PARAPLEGIA, FOLLOWED BY DEATH—WITH AN ACCOUNT OF THE AUTOPSY.

The object of the author was simply to put on record a case in which an autopsy was obtained in early syphilitic cephalgia. The patient was seen in consultation April 29, 1885. Two months previously the patient had begun to suffer with severe headache, worse at night. There was also a papular eruption. He acknowledged the existence of a sore six months previously. Iodide of potassium with chloral had been given two weeks later; the patient was free from pain, but it returned one month afterward when the patient stopped taking medicine. Iodide of potassium was again given with the effect of relieving the pain. Aphasia and paraplegia then developed, and the patient died four days later, and within nine months of the initial lesion.

At the autopsy the dura mater along the superior longitudinal sinus was thickened and adherent, there were numerous small gummata in the pia mater situated along the right border of the longitudinal sinus, and extended back to the fissure of Sylvius. The pia mater exhibited the evidences of simple acute inflammation.

The Association then adjourned.

Strabismus.—Dr. Samuel W. Francis says that squinting is caused by micro-cock eye!

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

SPECIALISM—THE OPPOSITION TO IT AND THE ARGUMENT FOR IT—THE BRITISH MEDICAL MEETING—ECHOES OF DISCONTENT.

LONDON, August 29, 1885.

THE subject of specialism is again being discussed, and, as usual, with some animus. It is one of those questions which is always coming to the front and being argued afresh, though each sucessive discussion usually does no more than leave matters *in statu quo*. *The Lancet* decided against specialism and specialists years ago, but the specialists continue to live and thrive in spite of *The Lancet*. The profession, at last, finding that they could not put down specialism, finally made some concession by establishing special departments at the general hospitals. Specialism was thus in a manner recognized and taken under the wing of the general hospitals. Eye diseases had long been acknowledged to constitute a legitimate specialty, but by this step other specialities were recognized as such. The "special departments" gradually increased in number and efficiency, until now most of the general hospitals in London—at any rate, most of those attached to medical schools—have them in the chief special branches. This has not, however, in any way lessened the number of special hospitals; the latter flourish in undiminished numbers. The fact is the public believe in specialism, and go to the specialists. They will, doubtless, continue to do so, whatever the general physicians and surgeons may say. From one point of view their argument is unanswerable. How, say they, can a man who practises all branches of medicine or surgery know as much about one particular branch as a man who devotes his whole time to that branch? In the case, at any rate, of those branches of practice which require considerable manipulative skill—such as ophthalmology, otology, laryngology, and, I might add, urethral surgery and operative obstetrics—the answer is self-evident. In the case of ophthalmology the question has long been settled in favor of the specialists. Take one of the others, though: a patient suffering from an aural exostosis, say, would naturally prefer to be operated on by an aurist who had previously done half a dozen or more similar operations, rather than by any general surgeon—however good as a general surgeon he might be—who had never done one. A patient suffering from a severe stricture, too, would rather have a bougie or catheter passed on him by a specialist who passed a score or more daily, rather than by a general surgeon in whose practice urethral cases did not form a tithe of those seen. The profession, too, believe in specialism. Many of them do, at any rate, for they send their patients to the specialists, and this not only among the general practitioners, who might perhaps be accused of not knowing any better, but also among consulting physicians and surgeons who have plenty of colleagues living within a few doors of them whom they might call in consultation if they would. In truth, many general physicians and surgeons are themselves more or less of specialists. They would, doubtless, repudiate the term with scorn. Yet a very large number of them have, without becoming out-and out specialists, devoted a disproportionate attention to some special branch, have perhaps written on it, and finally find that their practice largely consists of certain groups of cases. Look, for instance, at the number of physicians who have written on chest diseases. Many such have found their practice become mainly, if not exclusively, a chest practice. Are not these specialists? Certainly they are, to a limited extent.

Moreover, every general physician and every general surgeon is really a living example of specialism, paradoxical as this may sound. Yet this is so. They differ from the so-called specialist merely in degree. The thorough-going specialist would say that that he renounces the pursuit of general medicine and surgery in order that he may study one department more profoundly. He digs within a narrower area in order that he may dig deeper. Is not this what a general physician does, though his specialism is not so exclusive? Every pure physician renounces the practice of surgery and obstetrics, *i.e.*, he restricts himself to one-third of the healing art. Similarly, the pure surgeon relinquishes medicine and obstetrics. Each of them narrows his field of observation that he may explore it more minutely. Most people would admit, that, given two men of equal ability and, at the outset, equal professional attainments, and let one of them become a general practitioner and the other a pure physician, that, at the end of ten years, the latter ought at any rate to know the most *medicine*. The specialist merely carries the subdivision a little further.

Specialism is, however, open to great abuses, and these have justly been denounced. There is always the temptation, whatever the case may really be, to claim it for the particular specialty the consultant cultivates, and where the latter is unscrupulous, this has, no doubt, often been done, and in some cases to the detriment of the patient's interests. It is certainly not legitimate specialism for a laryngologist to retain a case of aortic aneurism even with laryngeal symptoms present, or for an ophthalmologist to keep a patient with Bright's disease even if albuminuric retinitis be present, or for an otologist to treat a case of Ménière's disease. If the practitioner is competent, it may be legitimate practice, but it is not *bona fide* specialism. It is, of course, possible for him to be a good general practitioner, and, in addition, a good specialist in his own specialty. It is, though, to be feared that the assumption of specialism has been occasionally a cloak for ignorance—that, in fact, a specialist has put himself forward as such, simply because he knew nothing else, and, perhaps, not even his own specialty. The abuses to which specialism is liable do not, however, detract from the arguments in favor of it, neither are they confined to specialism alone.

Now that the Cardiff meeting is receding from view and becoming a mere memory of the past, some signs of discontent are being manifested. Those who, when at Cardiff, were too busy in feasting, are now speaking out their minds—some in public, many more in private circles. One gentleman writes to the *Journal*, to complain that many who had promised to take part in discussions failed to appear, and that consequently the said discussions had to be brought to an untimely end. This is very sad, but not novel, and where is the remedy? Another gentleman complains that he has been misrepresented in the *Journal*, and states his case at some length in a rival journal. Dr. Jacob seems so far to have had the best of it. The editor of the *British Medical Journal* has, at any rate, deemed it wisest to maintain a judicious silence on the subject in his own columns. Many are the plaints, as usual, against the Council. It is stated that they can, by concerted action, carry anything. No doubt they can. Well-organized committees usually can. One very evident reason why any matter discussed at the annual meetings is usually settled in the way the Council wishes, is that most of those present apparently care little about the matters discussed, and are willing to leave it to the Council. This was very plain both at Cardiff and at Belfast. On each occasion considerable discussion took place over a proposal to pay the travelling expenses of members of the Council. On each occasion the proposal was negatived by a large majority, but it was painfully apparent on each occasion—and with respect to other questions also—that most of the members present cared nothing about the matter, one way or the other. Some opposition was evinced at Cardiff, to the proposed outlay on new premises, though it was finally sanctioned.

THE ABUSE OF MEDICAL CHARITY.

To the Editor of The Medical Record.

Sir: I have noticed with much interest the discussions in The Medical Record concerning the abuse of medical charities in this city, and it is to be hoped that the agitation will not abate until much of this abuse abates also. The existence of this misuse and perversion of what has been dedicated, in benevolent intent, to the benefit of the *really destitute* is well authenticated in all our large cities. A recent careful investigation made in Philadelphia shows that in one year about two and a half per cent. of the whole population received free in-door hospital treatment in that city, and nearly sixteen per cent., or 150,000 persons, received free dispensary treatment. Repeated tests in New York and Philadelphia, made to a somewhat large extent, have satisfactorily proven that fully two-thirds of this free treatment, in dispensaries at least, was bestowed upon persons fully able to pay a moderate fee to a regular physician. In the face of these facts, are the managing boards of our hospitals and dispensaries not guilty of unpardonable neglect of duty and misapplication of trust funds in permitting such miscarriage of charity?

The attendant disadvantages, also, in the over-taxing of the attending physicians, the injustice to the younger and struggling members of the profession, the disadvantage to the patients in hasty diagnoses and treatment, and especially in the corrupting effect upon the self-respect and independence of the poor, are too patent to require emphasis. The great need is a practicable remedy.

It must be borne in mind that the terms of medical relief should not be the same as those for other departments of charitable aid, inasmuch as the physical suffering, even of the most unworthy, cannot be ignored or neglected, and also because the relief dispensed cannot be readily pawned or traded for drink. The question of the right bestowal of medical relief will turn upon the applicant's pecuniary ability and not upon moral character.

A practicable remedy seems to be offered in New York in the near future, in the methods and system of the Charity Organization Society, a society organized by the State Board of Charities for the very purpose of offering a ready means for the proper protection, regulation, and adjustment of benevolent relief. When this society, which as yet covers only about one half the area of the city, shall be co-terminous with it, it is understood that it will be ready to undertake the investigations of all applicants for medical relief, and to report in ordinary cases upon the same before the second visit. It is even now willing to undertake such examinations within the territory already covered by it (Houston Street to Seventy-ninth Street on the East Side, and Houston to Fifty-third Street on the West Side), expecting that the institutions benefited thereby be willing to contribute correspondingly to the society's support. The results of the experience of the German Hospital and Dispensary in availing itself of the society's co-operation (as shown in The Medical Record of June 13, 1885) are sufficient to show the benefits and the thoroughness of the latter's methods. It is also understood that this society is at present willing to contract with a number of the medical charities to investigate over the whole city for a price sufficient to pay for the actual cost of the work. Its system of central registration of all applicants for relief, now three years in operation, gives an indispensable requisite for intelligent work. It already has registered about 70,000 families of seekers of charitable relief, or over 250,000 persons.

The general plan would be that all applicants for medical relief should apply primarily to the medical charities direct, and be treated upon the off-hand judgment of the medical attendant; and afterward be by him referred, with a card in proper form, to the society for report as to ability to pay before being treated a second time, the report to be made upon the same card. The report is to be a discriminating one, based upon the family income and number and condition of the members; and to state whether the party can pay any fee, or can pay a modified or an ordinary one. Any small *fixed* fee is as indiscriminate and as unjust to the medical institution and its benevolent supporters as no fee at all, and quite as liable to abuse. Under such a plan as is thus briefly outlined, it is believed that the co-operation of the Charity Organization Society could be equitably secured, and this flagrant abuse and perversion of medical charity seriously hindered, if not nearly altogether counteracted.

It may also be added that the same co-operative system of "Charity Organization," so technically called, is gradually spreading all over the country and now exists in nearly fifty of the large cities and towns of the Union. The kindred societies in all these localities are so closely allied that almost daily exchanges of information are made between some of them. This gives each city valuable protection against fraudulent relief askers from all the other towns.

Two examples from the Second Annual Report of the Society in question are to the point.

"Defrauding Hospitals.—Information was received by the Charity Organization Society of the coming to New York, from an interior city of Pennsylvania, of a wealthy man assuming the guise of great poverty, for the purpose of securing free treatment and surgical service for his eyes, for which he was able to pay liberally. The information having been carefully verified by real estate and tax searches, it was immediately sent out to every hospital and dispensary to which he would be likely to apply. He was thus discovered at a leading eye hospital, and in due time confronted with the facts and compelled to pay.

"Another.—A poorly-dressed woman applied to a hospital for surgical treatment, and was reported to the Society.' Investigation showed that she was the wife of a prosperous liquor dealer, who owned a valuable corner building in a choice location, the main floor of which was his elegant saloon, and the floors above rented out for high-priced flats. The hospital declined further treatment, and the other hospitals were duly warned."

Yours truly,

For Wisdom and Accountability in Charity.

COMPLICATIONS OF MALARIA.

To the Editor of The Medical Record.

Sir: Dr. Weber, of this city, a painstaking observer, published a paper in The Medical Record, of September 12th which is readable and interesting, also showing good treatment; but it seems to put forward as novel what has been known for a long time, namely, that in all febrile conditions, or fevers, there may be a succeeding determination to the viscera of head, chest, or abdomen; this causing hemorrhages or inflammations.

In the *New York Medical Gazette*, of January 7, 1882, p. 2, is an article by Dr. Thomson, on "Temporary Albuminuria, caused by Malaria;" which albuminuria was dependent on temporary renal congestion from malarial poisoning; intermittent hæmaturia was concomitant. This completely covers the ground taken by Dr. Weber as far as renal hæmaturia is concerned.

Other hemorrhages, of course, are also noted, such as epistaxis and hæmatemesis; I have had such (malarial) cases myself.

The apneumatosis (although prettily differentiated by Dr. Weber) and psychosis can, no doubt, be explained by internal determination. It is well known that malarial patients often temporarily lose complete memory, only retaining partial.

C. E. Nelson, M.D.

109 East Thirty-fifth Street.

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 6, 1885, to September 12, 1885.

McKee, J. C., Major and Surgeon. Sick leave still further extended three months on surgeon's certificate of disability. S. O. 204, A. G. O., September 7, 1885.

Patzki, J. H., Captain and Assistant Surgeon. Assigned to duty as Post Surgeon, Jackson Barracks, New Orleans, La. S. O. 192, Department of the East, September 8, 1885.

Polhemus, A. S., First Lieutenant and Assistant Surgeon. When relieved at Fort McDermit, Nev., assigned to temporary duty at Presidio of San Francisco, Cal. S. O. 87, c. s., Department of California.

Kendall, William P., First Lieutenant and Assistant Surgeon. Relieved from duty at Presidio of San Francisco, Cal., and assigned to duty as Post Surgeon at Fort McDermit, Nev., relieving Assistant Surgeon Polhemus. S. O. 87, Department of California, August 31, 1885.

Medical Items.

A Clever Impostor.—A Russian, who has been going about New Haven, Conn., soliciting alms on the strength of a badly swollen hand, which he told people was caused by rheumatism, was arrested a few days ago. At the hearing it was developed that the culprit was not afflicted with rheumatism at all, but had tied tightly a bandage around his arm, near the elbow, so as to make the blood settle in his hand and produce the swelling. A German present at the hearing said it was a regular trick of ordinary beggars in European cities. The prisoner was sent to jail for sixty days.—*The Medical and Surgical Reporter.*

The Cold Douche in Insomnia.—The following is recommended as a very efficacious means of producing sleep in insomnia associated with eruptive or continued fevers: The patient's shoulders are covered with a cloth and the ears plugged with cotton. Then the head being held face down over the edge of the bed, a fine stream of cold water is dropped upon the neck and occiput. The water should should fall from a height of eighteen inches during a period of three or four minutes. The head is then dried, and the patient made comfortable in bed. As a general rule, sleep follows in a very short time.—*Concours Médical.*

A New Cardiac Sedative.—Dr. G. Bufalini gives an account in the *Gazzetta degli Ospitali,* of August 12, 1885, of some experiments with coptis teeta or mameeran upon the heart of the frog. This plant is a native of China, belonging to the family of ranunculaceæ, and is used as a stimulant of the digestive functions. The author found its effects upon the heart to consist principally in a slowing of the pulsations, leading finally to complete arrest of cardiac action in systole. And he, therefore, classes it in the same pharmacological group with digitalin.

Floating Liver.—Maack relates the case of an unmarried woman, thirty-five years of age, who complained of pains in the right side of the abdomen. She had suffered from these for the past eleven years. Examination showed a tumor, of the shape and size of the liver, situated in the right iliac fossa, and the liver was also found not to be in its proper place. The cause of this mobility was thought to be an old echinococcus cyst of the suspensory ligament.—*Annales Médico-Chirurgicales.*

A Well-preserved Family.—There is an Arab family in Algiers, according to the *Gazette Médicale de l'Algérie,* which consists of Simon Lucas Gimenès, one hundred and eight years old, the father of François, seventy-eight years old, the father of Lucas, forty-six years old, the father of François, twenty-six years old, the father of Lucas, one year old. They are all in good health and all working with the exception of Simon Lucas and his great-great-grandson.

Oranges as a Galactogogue.—A case is reported in *The North Carolina Medical Journal,* of an increased secretion of milk caused by oranges. The patient gave little or no milk, and the child was fed artificially; but soon after eating some oranges she found that the secretion was markedly increased. When the fruit was omitted for a few days the milk was suppressed, but returned again upon the patient's returning to the orange diet.

The Evil Spoken of Physicians.—M. Witkowski has been collecting all the wicked things written about physicians, and has published them in a book bearing the title of "Le mal qu'on a dit des médecins." That we have had to suffer from a rather undue share of slander is evidenced by the fact that two volumes of between three hundred and four hundred pages each have already appeared, and are to be succeeded by still a third.

The Cocaine Habit.—A case is reported by Dr. Love in the *St. Louis Medical Journal* of an opium eater whom he treated with cocaine. He was successful in curing the opium habit, but found that his patient had simply exchanged that for the cocaine habit, and that he was as much a slave of the latter drug as he had been of opium.

Formula for Infantile Coryza.—Dr. Filatow recommends a solution of one part of hydrochlorate of quinine in fifteen parts of glycerine, in the treatment of infantile coryza. Two or three drops are to be applied by means of a camel's hair pencil to the nasal mucous membrane, three or four times a day.

It is said that manufacturers in Paris are imitating cod-liver oil by soaking herrings in olive oil. The olive oil quickly takes up the fishy odor, and closely resembles light cod-liver oil. Brown cod-liver oil is imitated by allowing the fish to soak in the oil for eight or ten days.

The Health of the French Soldiers in Tonquin.—Reports in the French journals of the health of the army in Tonquin continue to be unfavorable. The greatest mortality is from malarial diseases, which are very prone to assume a pernicious form.

Tuberculosis and Vaccination.—It is asserted by Straus that the proportion of tuberculous calves does not reach 1 in 100,000. If this statement be correct, there would seem to be but very little danger of tuberculosis in obtaining vaccine from these animals.

Oxide of Zinc, according to Professor Peterson, of Kiel, is much preferable to iodoform in the treatment of wounds. It is cheaper, not poisonous, has no offensive odor, and is equally effective as an antiseptic application.

To Arrest Hiccough.—Dr. Ramos asserts that hiccough may be at once arrested by wetting the lobe of the ear with cold water or with any fluid which by its evaporation will produce a slight degree of refrigeration.

Vaccination for Cattle-plague.—The success of Pasteur's method of vaccination for the cattle-plague in India is said to have been brilliant. It was used for elephants, cattle, horses, and sheep.

Honors to Billroth.—Professor Billroth has recently had the exceptional honor of receiving the gold collar and star of the order of St. James from the king of Portugal.

A Free College of Pharmacy has been established in Rio de Janeiro under the auspices of the Pharmaceutical Institute of that city.

ON CEREBRAL HEMORRHAGE.

By IRVING C. ROSSE, M.D.,

WASHINGTON, D. C.

As an indispensable prerequisite to the study of intra-cranial hemorrhage, it is important to know something of the details of the vascular distribution of the brain, and especially of the arterial distribution at its base. The subject has lately been elucidated by Stewart, Duret, Wernicke, and others.

At the outset, it is well to bear in mind as fundamental notions, that the cerebral vessels supplying the convolutions receive their blood from a set of arteries different from those that supply the ganglia and the neighboring parts in the encephalon; that the supply to these ganglia being much more direct, the vascular pressure is here greater than it is in the cortex; and that the vessels of the ganglia and of the cortex do not communicate; each ultimate branch supplying its own area, and for that reason known as terminal. The next point touches the origin and terminal distribution of the groups of nutrient arteries principally concerned in cerebral hemorrhage. The vessels of the antero-median group, given off from the anterior communicating artery and from its proximal parts, ascend into the cerebral substance and supply the front part of the head of the caudate nucleus; the posterior-median group, arising from the posterior part of the posterior communicating arteries and from the posterior cerebrals near their point of origin from the basilar, supplies the internal surface of the optic thalamus and the walls of the third ventricle; the right and left antero-lateral groups, given off from the Sylvian or middle cerebral artery of each side, pass into the brain substance and supply the lenticular nucleus and the adjacent parts of the internal capsule and anterior part of the optic thalami. One of its branches of relatively larger size enters the substance of the caudate nucleus by crossing the upper part of the internal capsule and spreads forward to the anterior part of the nucleus. This branch is known as *Charcot's artery of cerebral hemorrhage*. The nutrient groups, known as the right and left posterior lateral groups, given off from the posterior cerebrals after they have turned the crura cerebri, supply the greater portion of the optic thalami.

The cortex receives its arterial supply from the vessels that form the angles and sides of the circle of Willis; the middle cerebral being the most important of these vessels, since it is this artery and its branches that supply the convolution specially associated with aphasia and the great motor centres of Ferrier, and they are, moreover, the ones most subject to embolic and thrombic processes.

When a rupture of one of these arteries occurs, there results an effusion of blood into the lacerated brain substance or into the ventricles. The hemorrhage is in most all cases from a ruptured artery. It rarely occurs from a vein, and only from traumatic causes or from secondary invasion of the veins. In rare instances the obstruction caused by venous thrombosis may give rise to capillary hemorrhage, and it is also thought that a hemorrhage into the pia mater may ensue from the rupture of varicose veins. In the case of capillary or very minute hemorrhage, there is merely a separation of the cerebral fibres; but when the hemorrhage results from a ruptured artery it is followed by disintegration of a portion of the brain-tissue; by compression; by subsequent irritation and inflammatory changes; and by softening of the portions irrigated by the vessel. The effused blood forms for itself cavities varying in size from that of a pea to an orange, and they generally contain from fifteen to five hundred grammes of blood. The clot is large when the hemorrhage occurs in the ventricles, in the hemispheres, or in the cerebellum; small when in the motor tract. Its seat is more frequent in the right than in the left brain, and the hemorrhage occurs oftener in the corpus striatum and the optic thalami, or in this immediate vicinity, although it may take place in any part of the brain. Next in the order of frequency are the middle, the anterior, and the posterior lobes of the brain; then the cerebellum, the pons varolii, and the peduncles.

It sometimes happens that the effused blood tears through the white tissue and escapes under the pia mater and the arachnoid. It may escape further and be effused into the space between these membranes and the dura mater, or the extravasation may take place into the lateral or the fourth ventricle. The clotted blood, of a dark-red color, of gelatinous and homogeneous consistency and surrounded by a zone of reddish-yellow lacerated brain-tissue, undergoes a gradual change in consequence of the reabsorption of its coloring matter and the disarrangement of its elements. If the hemorrhage has not been very extensive, at the end of one or two months a part of the material of the clot is absorbed by the vessels of the vascular cyst enclosing it, leaving either a linear cicatrix, a reduced discolored clot, or a small cyst filled with reddish serosity or albuminoid gelatinous matter. In the case of a cicatrix resulting from the union of the cyst-walls, it is thought that such a result is owing rather to softening than to hemorrhage. When absorption does not take place a new hemorrhage into the same cavity may occur, or a secondary lesion or an abscess may result. The lesion in cerebral hemorrhage is sometimes multiple, double, triple, quadruple, and even more lesions having been observed, but as a rule in recent extravasations there is only one. Whether a clot be single or multiple, its varying dimensions form a basis for speaking of the hemorrhages as large, small, or medium. The small hemorrhages, resulting from the rupture of capillary vessels, now known as punctiform hemorrhages, are invariably multiple, while those in which the extravasated blood is collected into a mass, or the massive hemorrhages, are generally single. It is rare that the ruptured vessel causing the hemorrhage can be discovered. A miliary aneurism may, however, be found if the hemorrhagic mass be carefully washed out under water.

The history of what are known as secondary changes is so incomplete that a pathogenitic theory of these degenerations cannot be formulated. The secondary changes following hemorrhagic foci of long standing occur, not only in the brain and the cerebellum but in more remote parts, as the pons, the medulla, and the cord, and the change consists essentially of an atrophy of the nerve-fibres and the substitution of connective tissue. General atrophy of the brain is a common variety of secondary change accompanying extravasation into the cortex. There are also found in the paralyzed limbs,

alterations of the nerves, muscles, and the articulations. An interstitial inflammation may occur in the nerves of the paralyzed limbs, the volume of the nerves being increased to twice the size of those on the healthy side; degenerative changes are reported to have occurred in the tactile corpuscles of the skin, and atrophic changes involving the outer and subcutaneous tissue sometimes occur. Muscular atrophy and arrest or retardation of growth in the paralyzed limbs occur in some cases. In the first case the primitive fibres are atrophied; sometimes they have lost their striation, or have undergone fatty degeneration, and the nuclei of the muscular sarcolemmæ are increased. These changes are believed to be consequent upon secondary degeneration in the fibres of the anterior tract implicating the motor cells of the anterior horns of the cord. The articulations of the paralyzed side may suffer inflammation, either acute or chronic, and often occurring as acute synovitis with exudations, or as semi-dislocation of the shoulder-joint, attended with stiffness, pain on pressure, and atrophy. Hyperæmic conditions, or hemorrhages into the pleura or the lungs, the substance of the kidneys and suprarenal capsules, the endocardium, and mucous membrane of the stomach often accompany cerebral hemorrhages; but as these facts touch the changes occurring in these organs, they may be mentioned rather as predisposing causes of the disease.

As regards the etiology of cerebral hemorrhage, experimental investigations so far teach nothing, and the help from physiology is of little or no importance. The chief predisposing causes are to be found in diseases of the walls of the cerebral arteries or of their surrounding tissues; in increased blood-tension, and in certain changes in the composition of the blood. The existence of miliary aneurisms, the result of arterial sclerosis, is the most frequent cause of intracranial hemorrhage. Either primary or secondary fatty degeneration of the arteries, especially the branches of the Sylvian artery, is assigned as the most common cause of massive hemorrhages into the brain. Arterial tension as a cause of rupture is probably a pathogenetic element of secondary importance, an adjuvant or occasional rather than an efficient cause, since it is doubtful whether cerebral hemorrhage can occur from tension without vascular degeneration. In cerebral hemorrhage and albuminuria with hypertrophy of the left ventricle, the arterial tension is considerably increased, owing to the diminished renal circulation, and the arteries are, moreover, diseased in consequence of the dyscrasia. Tension of the cerebral arteries by collateral fluxion may cause hemorrhage on sudden exposure to cold. The tension may likewise be sufficiently raised to produce vascular rupture by all obstacles to the depletion of the encephalic veins. The same action may occur in consequence of a thrombosis of the sinuses, in compression of the jugulars or of the superior vena cava, in alterations of the right heart, and in obstructions to the pulmonary circulation, although it is probable that in these instances the hemorrhage is produced by vascular changes, a proof of which seems to lie in the fact that intracranial hemorrhage is almost unheard of in whooping-cough, epilepsy, and in labor, in all of which conditions the venous stasis reaches a great intensity. Embolism and thrombosis may nevertheless result in softening; and owing to the changed condition of the brain tissue and mobility of the vessels to resist the pressure of the blood, the state of brain-softening may influence the genesis of certain hemorrhages.

In exceptional cases cerebral hemorrhage is met with in leucocythæmia, pyæmia, hæmatophilia, scurvy, icterus, and the adynamic fevers. In the latter case, no alteration being shown to exist in the vessels, it is supposed that the red globules traverse the walls of the capillaries. Hemorrhages from pyæmia and leucocythemia are supposed to be caused by the obstacle which the accumulated white corpuscles oppose in certain points to the circulation and to the resulting excess of tension.

Cerebral hemorrhage, rare before the fortieth year, is most common in the male sex, and occurs generally between fifty and seventy.[1] Exact statistics on the subject are, however, wanting, since hemorrhages have not been made the subject of inquiry, but rather the occurrence of the symptoms traditionally known as apoplexy. An inherited tendency, occupation, climate, altitude, the abuse of opium, alcohol, and tobacco, gout and syphilis, the circumstance of a previous attack, and all causes that momentarily increase the circulation and increase the pressure of the blood, or retard its exit from the head, may equally favor the production of a hemorrhage.

There are striking differences in individual cases of cerebral hemorrhage; but almost all cases present two essential features, namely, suddenness of onset of the initial attack, and subsequent evidences of local cerebral disease with hemiplegia.

Many writers speak of the so-called prodromata of cerebral hemorrhage, which bear a similarity to the group of symptoms that accompany cerebral hyperæmia, or symptoms of diffused vascular lesion that may lead to softening. These symptoms are headache, vertigo, ringing in the ears, muscæ volitantes, vomiting, slight confusion of mind with dysphasia, numbness of a limb or of one side of the body, and various motor and sensory disturbances. Agoraphobia is reported to have been a premonitory symptom in some cases. Disturbances of the vision, as diplopia, neuro-retinitis, and amaurosis, have also been observed to precede attacks of cerebral hemorrhage, and the presence of miliary aneurisms upon the retinal vessels incline to the belief that the same alterations exist in the encephalon, and are therefore a presumption in favor of hemorrhage.

As a rule, the irruption of blood upon the brain is sudden; the patient, in apparent good health, being suddenly struck down by the shock, which causes total abolition of the encephalic enervation, with paralysis of all the limbs, stertorous respiration, deviation of the eyes to one side, and loss of the reflex movements, with the exception of deglutition, respiration, and the movements of the heart. After this state of sopor, the victim of the seizure may die sooner or later. It is rare that cerebral hemorrhage is instantly fatal, unless the extravasation be in the medulla oblongata, or in both hemispheres. In the slighter forms sudden loss of consciousness gives place to other symptoms, a simple onset being attended by paralysis or tonic spasms of the extremities. Epileptiform convulsions sometimes accompany the onset of the extravasation, but this is rare. Other features of an attack are variations of the bodily temperature, the pulse, and the respiration; the appearance of the face, and the condition of the pupils. In the fulminating form, the temperature sometimes sinks to 95.5° F., and may remain lowered until death. In some fatal cases the primary depression may rise steadily until 108° F. is reached. A slow, irregular pulse is most often observed; sometimes it may be just the opposite, and the tension may vary with the case. The respiration is not always stertorous, being sometimes as quiet and regular as that of ordinary sleep, and in some cases it takes on the Cheyne-Stokes character, owing to the depressed action of the respiratory centre. The face is sometimes injected and cyanosed, owing to incomplete hæmatosis; at other times it is quite pale, and the features are expressionless. Occasionally there is nystagmus, and if the hemorrhage has taken place into the pons a high degree of myosis. A marked degree of inequality in the size of the pupils points to unilateral affection of the brain. A temporary symptom in some cerebral hemorrhages is conjugated deviation of the eyes, with rotation of the head toward the side not paralyzed. The deviation does not hold good in all cases. As a diagnostic aid to determine the

[1] It is met with in the lower order of animals, having been observed in monkeys.

site of lesion, it is thought that lateral reflection of the head and eyes, or of the latter alone, points to hemorrhage in the territory of the posterior cranial fossa, or rupture into the ventricles. On the other hand, deflection toward the opposite side points to the hemispheres. Cerebroscopic appearances, such as dilatation and tortuosity of the retinal veins with serious papillary infiltration or retinal hemorrhage, indicate sudden interruption of the interior circulation of the brain.

The further history of cases that survive is that of the disturbances following permanent destruction of the brain-tissue. The most prominent of these focal symptoms is paralysis of voluntary motion, the so-called cerebral hemiplegia. Other permanent symptoms are contractures or hemispasms, hemianæsthesia, hyperalgesia and persistent neuralgic pains, affections of the special senses, trophic and vasor-motor disturbances, such as œdema of the skin and change in its perspiratory function, the pulsus differens, bed-sores, etc.; and more or less impairment of the intellect. The electrical reaction of the muscles of the paralyzed parts remains unchanged, or nearly so. Movements of an athetoid character are sometimes noticed in the limbs. Disturbances of the special senses occupy but a secondary place in the symptomatology of the chronic condition. Anosmia never occurs as a consequence of cerebral hemorrhage; taste and hearing are but rarely affected; and but little definite is known regarding the disturbances of vision. Optic neuritis seldom occurs, but hemiopia or hemianopsia is, however, often present. A lesion of the first temporal convolution on the left side is said to give rise to an auditory disturbance in which sounds are heard distinctly; but the patient does not understand what is said to him, and gives wrong answers to questions. Secondary implication of the corpora quadrigemina is also thought to be a probable cause of such symptoms as amblyopia amaurosis, and mydriasis.

Full mental vigor is seldom regained after an attack of cerebral hemorrhage. Failure of memory is generally the first noticeable mental symptom. Aphasia sometimes occurs; the emotions are under bad control, the patient laughing at inconsiderable trifles, and sobbing at the slightest irritation; and in some cases the intellect declines into childishness and oblivion.

From many of the foregoing symptoms, it is possible, in the presence of certain definite conditions, to decide the position of the hemorrhagic lesion in the brain, if not positively, at least approximately. The science of localization is new, and writers, though agreeing in the main, are not in accord on this subject. In a general manner it has been determined that deviation of the eyes and rotation of the head away from the paralyzed side, indicate which hemisphere is attacked; that convulsions and contractures denote whether the lesion be in the excitable part of the encephalon, that is, the peduncles, the pons, or the cerebellum, and whether the irruption of blood be in the ventricular cavities or on the surface of the encephalon; that the antagonistic paralysis of the limbs, and of the parts supplied by the cranial nerves, permit the localization of the focus in the bulb, the medulla, or the cerebral peduncles, according to the implicated nerve. Beyond this the possibility of locating a hemorrhagic lesion is largely a matter of conjecture. Moreover, it is often embarrassing to differentiate cerebral hemorrhage from embolic or thrombic softening of the brain, which is characterized by many of the same phenomena.

Patients may live for many years after an attack of cerebral hemorrhage, but sooner or later the hemorrhage reappears with fatal effect, or an intercurrent malady, generally pneumonia, may end the life. Others succumb to the enfeeblement brought on by long repose in bed, and the unfavorable hygienic condition resulting from the hemiplegia; paralysis of the bladder and rectum may ensue, with bed-sores, and death occurs from adynamia.

There should be no difficulty in diagnosing cerebral hemorrhage after becoming acquainted with its symptomatology: but there are, nevertheless, several conditions of insensibility that may prove misleading, such as those resulting from intoxication by alcohol or opium, the coma uræmia, or of epilepsy, and the profound insensibility following injuries of the skull cerebra hyperæmia, arterial obliteration, encephalitis, meningeal hemorrhage, and intracranial tumors. An attack of syncope, of asphyxia, or of hysteria may often complicate the diagnosis. To distinguish the foregoing affections from cerebral hemorrhage, it is necessary to compare their fundamental symptoms with those of hemorrhage in connection with attending circumstances and the patient's antecedents. Nevertheless, it is often impossible to diagnosticate a cerebral hemorrhage with effusion into the ventricles or under the meninges from a subarachnoid hemorrhage without alteration of the encephalon, since the symptoms of a cerebral hemorrhage are sometimes reproduced in meningeal hemorrhage, and convulsions and contractures may be observed in both affections.

The grave consequences of cerebral hemorrhage are in a measure indicated by the character of the initial symptoms, the seat and extent of the lesion, and the age and previous health of the patient. The lesion is probably very extensive, and the issue of the attack correspondingly grave in the fulminating cases, when there is sudden and complete resolution, abolition of reflex excitability of the pharynx, and considerable fall in bodily temperature. If this state be prolonged and convulsions and contractions be added to the symptoms, the extravasation has probably made its way into either the brain cavities, the cortex, or the mesocephalon—an event that almost invariably leads to a fatal determination. Hemorrhages of this class being more frequent in middle-aged and in old people, the prognosis at the outset is less favorable than it would be in the young. The existence of a bed-sore shortly after an attack is a sign of fatal significance; so are great depressions or rapid rises of the bodily temperature, and reactive inflammations, with headache and contractures of the paralyzed limbs. A sad result is likewise to be feared if the patient has previously had one or several attacks; and the ultimate prognosis is equally bad in all cases of physiological ruin or decay, as in senile degenerations, chronic kidney diseases, and the like.

If the patient do not die in the attack, and he should resist the subsequent phenomena of the disease, he is always subject to another attack, unless carried off by adynamic symptoms or an intercurrent malady, as encephalitis or pneumonia, and he is left with an incurable infirmity, and often with a weakened mind.

The prognosis, on the contrary, is usually pronounced as favorable if the attack has come on in a young person as the result of muscular or mental strain; nevertheless, hemorrhages occurring in infants and children often leave them in an idiotic condition. It is also held to be a favorable augury when there is no loss of consciousness and but little paralysis. Even in the mildest cases it is doubtful whether a patient ever completely recovers. Such an event is probably rare, and the question is open to much discussion.

There are no absolute rules for the treatment of this affection, and the symptoms are usually uninfluenced for good, even after the most energetic and well-considered efforts.

In attempting to avert a threatened attack, it must not be expected that a prophylactic influence can be exerted in such conditions, as the presence of miliary aneurism or granular disease of the kidneys with cardiac hypertrophy; but many of the exciting causes, which are identical with those found in cerebral hyperæmia, may be removed or prevented by proper measures. When the state known as agoraphobia is thought to be a predisposing cause of cerebral hemorrhage, therapeutic measures should be taken accordingly.

During the occurrence of the hemorrhage, the tendency of physicians in times past was to do too much. The attack is best treated by judicious inaction, such as perfect quiet in a cool room; elevated position of the head, the removal of a tight collar or any other cause of passive congestion; cold to the head, dry cups to the surface, and the employment of such derivative agents as diminish the cerebral hyperæmia. Although the former advocates of venesection have laid down rules for its employment in this affection, and claim with a certain degree of probability that intra-cranial pressure is diminished thereby, its employment should be resorted to with great caution, even in the cases that correspond to the indications for blood-letting, since in most cases it only hastens the final result by weakening the cardiac action.

The use of stimulating agents is advisable, to counteract the failure of the heart and of the respiration, resulting from incomplete hæmatosis and paralysis of the respiratory centre. Dashing cold water in the face; cutaneous irritation by various methods; ammonia to the nostrils or administered internally; the administration of coffee, wine, and musk—which may be given by enema if the patient cannot swallow—are each useful in arousing the depressed action of the respiratory action of the cardiac aud respiratory centres. Cold is effectual in checking the convulsions. A laxative enema may be administered if the bowels are constipated, and if necessary, the catheter should be used.

After the attack is over, the less that is done to allay excitement during the inflammatory reactive stage that follows the better. Enforcement of intelligent hygienic rules and the occasional administration of a sedative are about all that we are justified in doing.

The symptoms of irritation having passed, the object of treatment is to promote the absorption of the extravasated blood and to improve the condition of the paralyzed nerves and muscles. Galvanism is the most useful agent we know of to bring about this object. It should be applied to the brain, to the cervical sympathetic, and to the muscles, in conjunction with massage and hydro-therapeutics. It does not appear that much benefit has resulted from the faradic current.

The cures reported to have taken place after the application of strong magnets and other metallic appliances, are probable instances in which the lesion was mainly situated on the optic thalamus. Hemiplegia following a lesion of this organ, being more or less transitory, it is impossible, in the absence of a convincing number of clinical cases, to separate the specific influence of the magnet from what may be mere coincidence or the result of strong mental suggestion. It would, therefore, be premature to formulate an opinion as to the merits of a plan of treatment as recent and imperfect as that employed in the metallo-therapeutic method. Nevertheless, from the great number of interesting facts in connection with the subject, it merits further inquiry.

The Vatican Hospital.—A correspondent of the *Allgemeine Wiener Medizinische Zeitung* describes the new hospital, built by the Pope, for use in time of epidemics. It has 200 beds, and is provided with every improvement which modern experience has been able to suggest. Over the main entrance is the inscription: Munificentia Leo. XIII. Upon admission to the hospital, the patients suffering from cholera or other epidemic disease, are first taken into a large reception room, where their clothes are removed and thrown into a disinfecting trough. They are then carried to the upper floors by a hydraulic elevator. In each room is a metal tube through which either warm water or steam is conducted, and for every floor is a large, light and airy bath-room. For patients in the algid state of cholera there is an apparatus made of glass in which they may receive a vapor bath. The rooms are light and well ventilated.

A MODIFICATION OF THE PROCEDURE OF WIRING BONES,

With a Description of New Instruments devised for that Purpose.

By WILLIAM F. FLUHRER, M.D.,

Professor of Clinical and Operative Surgery in the New York Post-Graduate Medical School, Visiting Surgeon to Bellevue and Mount Sinai Hospitals.

To overcome the difficulties in the wiring of bones, I devised the instruments and have for several months practised the procedure described in this paper.

The drill, which is shown in Fig. 1, *a* and *b*, is made of one solid piece of steel. Its handle is octagonal, one-fourth of an inch in diameter and four inches long to the shoulder, which tapers quite abruptly to the shank.

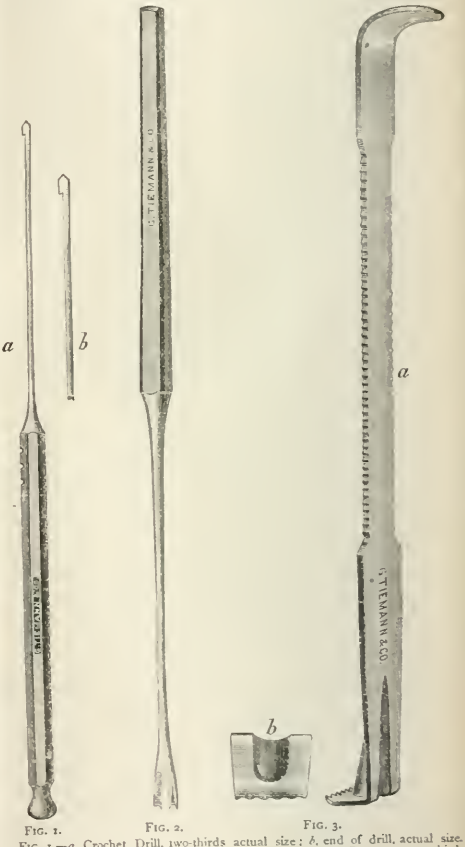

Fig. 1. Fig. 2. Fig. 3.

Fig. 1.—*a*, Crochet Drill, two-thirds actual size; *b*, end of drill, actual size. Fig. 2.—Fork, two-thirds actual size. Fig. 3.—*a*, Grooved Retractor, two-thirds actual size; *b*, front view of end of retractor, actual size.

The shank is one-sixteenth of an inch in diameter, two and three-quarters to four inches long, of fine spring temper, and terminates in a flattened head which is a little wider than the diameter of the shank. The peculiar feature of this drill is a shallow notch cut into one side of the head and forming the end into a hook. It is important that the notch shall not be made too far from the point, that it shall not be too deep, that the side of the head beyond it shall have exactly the shape shown in the figure, and that whatever the other dimensions of the drill it shall always be constructed just as described. Three transverse grooves upon the handle, near the shoulder, are an index to mark its position with reference to the circumference of the instrument.

The FORK is shown in Fig. 2. It is also made of one solid piece of steel and is finally annealed. Its flattened handle, four inches long, is continuous with the shank, also four inches long, which gradually tapers to a diameter of one-eighth of an inch, and which terminates in a double fork. The prongs of the primary fork are three-eighths of an inch long, and at their ends are notched one-eighth of an inch deep, forming secondary forks.

FIG. 4.—Wire Suture, two-thirds actual size.

The GROOVED RETRACTOR is made of German silver or other metal, and is shown in Fig. 3, *a* and *b*.

The WIRE is of pure silver, annealed. It is used of different thickness, and, if practicable, it should be large enough to nearly fill the drill hole. A large-sized wire is not apt to cut through the bones, and forms a strong bond of union between them. The ends of each length of wire are tapered for about two inches and bent at an acute angle as shown in Fig. 4.

The procedure is as follows: The bones to be wired are sufficiently bared, but need not be completely denuded. The withdrawal of the soft parts for drilling through the smallest possible incision is effected by means of the grooved retractor, which not only retracts but at the same time depresses the obstructing tissues. The drill is passed along the channel of the retractor directly to the bone, cutting its way through any overlying soft tissues by an incomplete rotary motion. When the bone is reached the drill should never be withdrawn in any degree for fear of fouling, but should be urged onward by a rotary motion with continuous and light pressure. The drill being made in one piece, and larger at its head than in the shank, its progress, like that of a probe, can be nicely felt as it passes through the bone, which would not be the case were the mechanism for drilling a complicated one or were the drill driven at high speed. In drilling transversely through a bone, as in the case of the upper end of the tibia, the passage of the head of the drill through the proximal portion of compact bone, through the cancellous structure, the striking of the distal portion of compact bone and its passage through it can all be clearly discriminated.

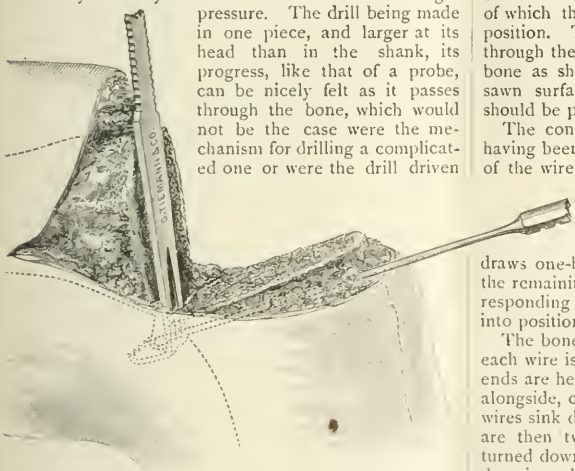

FIG. 5.—The grooved retractor in use, to expose the notch of the drill in wiring after an excision of the knee-joint.

The emergence of the point of the drill having been detected by the finger watching at the presumed place of exit, or being known by the change in resistance, the next step is to pass a loop of silk through the bone to serve as a conductor for the wire suture. The silk should be of a thickness barely large enough to fill the notch in the drill. When the end of the drill is far below the surface, the fork is needed to deposit the thread in place. When the soft parts crowd upon the buried end of the drill, they should be pressed back by using the retractor, as shown in Fig. 5; then the end of the drill is received into the groove of the retractor, and is easily accessible to the fork carrying the loop of thread. When the silk has been lodged in the notch, it is held there by gentle counter-traction, while the drill is cautiously withdrawn without rotation, leaving the thread in its place. When the end of the drill is far below the surface the counter-traction may be exerted through the medium of the fork. By a dexterous movement the loop may be shifted from the secondary forks (Fig. 6, *a*) into the crotch of the primary fork (Fig. 6, *b*) around which it plays as a pulley as it is drawn through the bone. It is essential that the closed ends of the loops should lie between the bones to be wired. If, therefore, a loop needs reversing, a second thread is passed through the existing loop, by means of which the new loop is pulled through the bone into position. The free ends of the thread are then passed through the loop and drawn tightly across the face of the bone as shown in Fig. 7, thus lining off the broken or sawn surface, and indicating clearly where the drill should be passed through the opposing bone.

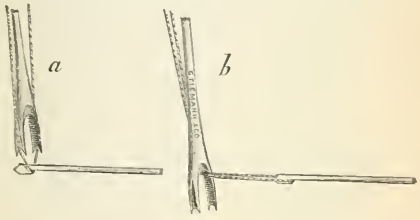

FIG. 6.

The conducting loops, or guides, for the wire sutures having been lodged in place, the next step is the drawing of the wires into position. The bent end of the wire suture is hooked in the end of a loop of thread which has been freed, and under a little counter-traction is fed to the opening, while the operator pulls upon the conducting loop and draws one-half the wire through the bone. The end of the remaining half of the wire is then caught into a corresponding loop through the opposing bone, and is drawn into position.

The bones having been brought into close apposition, each wire is embedded before being twisted. While the ends are held in their future position the scalpel is drawn alongside, cutting the subjacent soft parts and letting the wires sink down to the bone. The tightly drawn ends are then twisted and cut short to the twist, which is turned down. The slits in the soft parts are closed over the wire, which is to remain permanently, by a fine catgut suture.

By proceeding in the manner I have detailed, the wiring together of bones is a precise, easy, and expeditious operation. It can be done without extruding the ends of the bones through the soft parts, it being only necessary to cast the guiding loop of thread over the end of the drill, no matter how deeply the latter may be situated. It is easy to carry the wire transversely through the whole extent of bone, thus securing an effective hold upon it. A suture only dipping into the cancellous structure, as is the case in the usual mode of wiring after an exsection of the knee-joint, may be regarded as a slack wire. It

generally cuts partly through the soft bone tissue before the surgeon can apply retentive apparatus to the limb. On the contrary, when the sutures have been passed completely through the bones in the manner just described, they alone hold the bones firmly in apposition, and the grating formed by the wires prevents the intru-

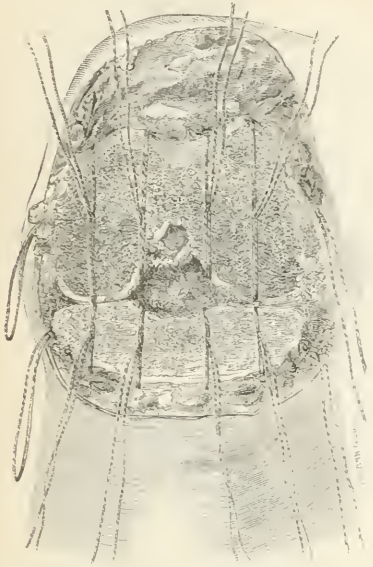

Fig. 7.—The loops of thread in position preparatory to inserting the wire sutures, after an excision of the knee-joint.

sion of the soft parts. In an exsection of the knee-joint, in addition to four wires passed antero-posteriorly, I also bind the bones together by a wire passed transversely, which acts as a substitute for the lateral ligaments. In simple fractures of the patella, exsections of the knee-joint, and compound fractures, I have passed the drill more than thirty times, besides being present when others have operated in the same manner, and I have never seen a failure or miscarriage in the execution of any step of the procedure.

What some Great Men thought of the Corset.—Napoleon Bonaparte said to Dr. Corvisart, speaking of the corset, "This wear, born of coquetry and bad taste, which murders women and ill-treats their offspring, tells of frivolous tastes, and warns me of an approaching decadence." Joseph II. of Austria was very severe upon the corset, and made a law confining its use to abandoned women. The last King of France embodied his opinion of this abomination in this stinging epigram: "Once you met Dianas, Venuses, or Niobes; nowadays, only wasps." The great naturalist Cuvier was walking one day with a young lady, who was a victim of tight-lacing, in a public garden in Paris. A lovely blossom upon an elegant plant drew from her an expression of admiration. Looking at her pale thin face, Cuvier said, "You were like this flower once; to-morrow it will be as you are now." Next day he led her to the same spot and the beautiful flower was dying. She asked the cause. "This plant," replied Cuvier, "is an image of yourself. I will show you what is the matter with it." He pointed to a cord bound tightly round the stem, and said, "You are fading away exactly in the same manner under the compression of your corset, and you are losing by degrees all your youthful charms, just because you have not the courage to resist this dangerous fashion."

INTRACRANIAL CEPHALHÆMATOMA.[1]

By E. S. McKEE, M.D.,

CINCINNATI, O.

A physician's library will, in many instances, give him no information concerning cephalhæmatoma. A large list of text-books may be searched to no avail for a mention of "intracranial cephalhæmatoma." Has the searcher after medical knowledge a well-ordered and extensive public library at hand, well supplied with bound journals, diligent search may be rewarded by a few hidden points. The word "cephalhæmatoma" comes to us from the Greek. It is an effusion of blood occurring in newly born infants, forming a tumor of the head.

The intracranial variety, the subject of this paper, is divided into (*a*) those situated between the skull and dura mater; (*b*) those occurring in the arachnoid cavity.

As causes of intracranial cephalhæmatoma may be enumerated most of the causes of the external variety, as, for instance, the reception of some injury to the child during parturition.

One can, however, find many instances where the external variety occurred, the labor being light. They are mentioned in breech cases, and, in Vienna, have been noticed on those delivered by Cæsarean section. It is quite possible that through the crushing of the parts of the head together during delivery, there occurs tearing of the periosteum and bone blood-vessels. This pressure being released, the parts are again suddenly freed. Emptied by the diapedesis, caused by the crushing which they had undergone, hyperæmia and engorgement are the results of the removal of this pressure. Thus, from nature's horror of a vacuum, we have a sudden rushing of blood. The sources of the hemorrhage are probably the tender blood-vessels. These enter the bone from the dura mater, and are immediately after the release of the pressure overfilled and ruptured. Possibly it might be due to a varicose condition of the vessels. The hemorrhagic diathesis might be a cause. The tendency in some instances is probably inherited. In cases of fracture of the bone, cephalhæmatoma on the dura mater may be due only to the hemorrhage from vessels wounded by the broken edges of bone. Feist and others decline to recognize as cephalhæmatoma those instances where effusions of blood occur after fracture. The fact should be borne in mind that cephalhæmatoma, both external and internal, occurs without the coexistence of fissure of the cranial bones. Admitting that the extravasation of blood results from its escape out of the blood-vessels which are wounded by a fissure of the bone, the centre of each tumor must correspond with the fissure. This has, however, not been found to be the fact in the cases reported. The fissure and effusion may occur at the same time and from the same cause, but the latter must not be considered a result of the former. M. Valleix, in his "Clinique des Enfants Nouveau-nés," has an engraving which illustrates beautifully the ease with which the blood may be caused to transude through the imperfectly ossified skull of the child. The direction of the pressure during labor and the greater porousness of the outer than the inner surface of the skull, accounts for the excess of the extra over the intracranial variety. The usual causation of the former—pressure—is quite adequate, if unusually forcible, to cause the latter.

The diagnosis of intracranial cephalhæmatoma depends wholly, of course, on the symptoms of brain pressure which it is liable to occasion. These are twitchings, convulsions, stupor, or paralysis. The external variety is, of course, much more easily diagnosed.

While the prognosis for the extracranial variety is good, that for the intracranial is bad. Death occurs most frequently from brain-pressure, or from necrosis or caries of bone leading to perforation, thrombosis of the cerebral sinus, extension of the inflammation to the meninges and

[1] Read before the Mississippi Valley Medical Society, September 9, 1885.

brain itself, and pyæmia. Iodicy is one of the results of internal cephalhæmatoma. Dr. West is the only observer who watched the cure of internal cephalhæmatoma. This was very analogous to the repair of the external. The effusion became encircled by an osseous ring. In one of the two cases noticed by Dr. West, convulsions came on in fifteen hours and terminated in death in forty-one hours. A large quantity of blood was found post-mortem beneath each parietal bone. The effusion of blood upon the surfaces of the brain does not immediately and universally cause cerebral symptoms. This is probably due to the yielding structure of the infantile skull with its membranous joints and unossified sutures. In one of Dr. West's cases all went to prove that the effusion beneath the dura mater must have existed many days before there were any cerebral symptoms. From all the literature I am able to obtain, mention is made only of the following cases, which are briefly recapitulated.

West [1] reports as follows: E. W——, aged sixteen days; the fourth child, all easy labors. The birth took place without noteworthy occurrence. Took the breast well. On the third day a small swelling about the size of a walnut was noticed a little to the right of the vertex, extending downward and forward over the parietal bone. The tumor increased in size every day, but the child's health remained undisturbed, except that it was restless at night. It was well nourished, well formed, and perfectly healthy in its appearance. Pupils responded readily to light.

Neither the fontanelles nor the sutures were remarkable for tardy or precocious ossification. A soft, elastic, non-pulsating, semifluctuating tumor, of irregular, oval outline, occupied nearly the whole of the right parietal bone. The greater prominence of this tumor was just over the parietal protuberance, a little above which was a light depression or furrow, and again a second prominence, the base of which reached almost to the sagittal suture. The tumor was thus divided into two, that nearer the vertex being the softer and more manifestly fluctuating than the other. Both tumors were twelve inches in circumference. They did not anywhere extend beyond the sutures bounding the parietal bone. The ossified ring was absent. The child seemed uneasy while its head was being examined, but did not cry, and pressure on the tumor had no effect on the nervous system. On the fourth day the child appeared well, and the tumor had ceased to enlarge. Three days later there was no obvious diminution of the tumors, but that over the parietal protuberance was rather firmer. On the evening of this same day the child became very drowsy, had convulsive twitchings of the muscles of the face, and the skin of the surface assumed a yellowish hue. The child sucked heartily, but vomited in a short time, and passed an unquiet night. On the afternoon of the next day she yawned deeply two or three times, and then had an attack of general convulsions which lasted about three minutes. During the night she continued very ill, convulsed at four o'clock in the morning, and died in convulsions at 6 A.M., the ninth day after the doctor first saw her, and the twenty-fifth day of her life.

Post-mortem, thirty-three hours after death, with permission to examine only the head. The usual appearances were found external to the pericranium. These do not bear directly on this paper, and are omitted. A fissure was then noticed in the right parietal bone, running from the coronal suture, about an inch from the anterior fontanelle, obliquely backward and upward. The edges of this fissure at the time of making the examination were quite clean, not stained with blood as they afterward appeared. On the inner surface of the bone was an effusion of blood, between the cranium and the dura mater, more than half an inch in thickness, and occupying the whole of the fossa of the parietal bone. The tumor was oval-shaped and slightly irregular. Between the two layers of the dura mater, by which it was covered, were numerous bony deposits, and a ring of newly formed bone surrounded its base. This ring had not attained the same development in its whole circumference. Osseous matter had been abundantly poured out along the frontal margin of the tumor, more sparingly elsewhere, and being entirely absent along its inner border. It appeared to have been formed partly by ossification of the dura mater, partly by heaping up of new bone on the skull. To avoid the destruction of the specimen, the clot was raised on one side only, but on that the bone was found perfectly smooth and unaltered. The blood seemed to have been poured out in successive layers, none of which were of very recent date, since all were firmly coagulated. The red particles had not subsided, but remained equally diffuse throughout the clot. The rest of the dura mater and interior of the skull presented no unnatural appearance. There was a depression of the right hemisphere of the brain, in a situation corresponding to the tumor; with this exception the convolutions of the brain presented a perfectly natural appearance, and there was no fluid beneath the arachnoid, nor any injection of its vessels. The whole right hemisphere was pale, bloodless, and very soft. The left was of natural consistence, but its section presented an unusually large number of bloody points. There was no fluid in the ventricles, but little blood in the sinuses, and no appearance of importance was observable in the brain. No evidence or history of external violence could be obtained. After summing up the case, the doctor thought the fissure had occurred during labor, and was probably produced by the uterine action driving the head forcibly against the promontory of the sacrum.

While on duty in the out-patient obstetrical department at St. Bartholomew's Hospital, under Dr. Mathews Duncan, the writer [1] was called to attend Mrs. E. W——, 80 Farringdon Road Buildings, London. A breech presentation was diagnosed, and a healthy female child was born, the labor being quite easy. The mother was aged forty-seven, married twenty-seven years, and had given birth to thirteen children, six of whom had died, and two were still-born. Saw the child the next day, it was doing quite well, and seemed to be a very promising child. On the morning of the third day the child appeared fretful. Nurse said it had not passed its water yet, but it passed it that instant in my presence. Called on the evening of the fourth day, and found the child dead in bed beside its mother, still warm, the mother not yet aware of its death. She gave the following history: Child began having convulsions at 5 P.M., on the third day; had two per hour all night until noon of the fourth day, when it began having three per hour, and died as stated, having cried five minutes before my arrival. She said that three of her other children had died of convulsions, and she gave this one up to die as soon as they came on. She thought the doctor could do it no good, and did not bother him.

Autopsy, twenty hours after death, made in company with Mr. H. C. Cronk, midwifery assistant to the hospital. Body well nourished and fat. Head presented nothing unusual externally. An excision through the scalp, from mastoid to mastoid, found the skin normal; but between the scalp and pericranium a large effusion of blood was found, coagulated, extending over a great part of the left parietal bone, and not surrounded by any indurated ridge. On opening the skull, the bones were found in a perfectly normal condition, the dura mater healthy, but in the cavity of the arachnoid, and corresponding in position to the outer tumor, a large clot of blood was found, causing a depression of the brain, one-half to three-quarters inch in its deepest part, which was one inch to the left of the posterior fontanelle. The effusion was larger than that externally, reaching down to the foramen magnum. No ruptured vessels could be discovered. Other parts normal. All investigation of the

[1] Transactions Cincinnati Academy of Medicine. Cincinnati Lancet and Clinic, October 13th, 1883.

most careful kind failed to get any history of a blow, fall, or injury, either before, during, or after delivery. After thoroughly sifting the matter, the death certificate was signed intracranial cephalhæmatoma.

Dr. J. L. Cleveland [1] showed the following specimen to the Cincinnati Academy of Medicine. A well-nourished child, still-born, died probably five days before birth, and weighed eleven pounds. Discovered an external tumor before delivery, but mistook it for the bag of waters. There was no unusual amount of pressure during labor. The mother had previously borne two healthy children. No miscarriages. Autopsy performed in the presence of the Academy. Discovered an internal tumor and depression of the brain.

Dr. Jackson [2] reported a case which had been examined post-mortem. Tumor on the inside of the occipital bone with ossification of the pericranium. No thinning of the bone and no disease externally.

Ruge [3] demonstrated to the Gesellschaft für Gynekologie in Berlin a skull with internal cephalhæmatoma. The child was born without artificial help, and died soon after delivery, somnolent.

Ruge [4] showed another skull with cephalhæmatoma, both external and internal. In this case, on account of a straight, narrow pelvis, it was necessary to use the forceps. The child died after eight days. There was no fissure of the cranial bones.

West [5] mentions a case where hemorrhage into the cavity of the arachnoid was associated with internal tumor.

Betscher [6]: Dr. West mentions this case as one of internal cephalhæmatoma, but could not give the particulars, and I was unable to find them myself.

Von Siebold [7]: Forceps delivery, but the child's head was uninjured. Both external and internal cephalhæmatoma existed. The child died with symptoms of exhaustion on the fifth day.

Held [8]: Labor natural, except that the funis prolapsed. Child still-born, with subaponeurotic and intracranial cephalhæmatoma. Bone uninjured.

Dubois [9] relates a case which had occurred to M. Moreau. The skull received no injury, and there was no external cephalhæmatoma. The tumor was situated on the inner surface of the os frontis. Death was preceded by head symptoms.

Padieu [10]: Child still-born. Fracture of the parietal bone, two inches long. External and internal cephalhæmatomæ, which communicated readily with each other through the fissure.

Haere [11]: Quick labor, fracture of the right parietal bone. Internal and very slight external cephalhæmatoma. Head symptoms from birth. Death on the fourth day.

Bouchard [12]: Case V. is one of fissure of the parietal bone in a premature fœtus. External and internal cephalhæmatoma. Death from marasmus on the twenty-first day.

Bouchard [13]: An oblong aperture in the base. External and internal cephalhæmatoma. Death in coma on the ninth day.

Hennig [14] reports finding four cases of intracranial cephalhæmatoma, but gives no particulars. He also refers to a case of Olshausen's, where there was fracture of the skull caused by precipitate labor.

These twenty cases are all that it is possible to find mention of in the literature, and, I think, are about all that have been observed.

Treatment can be disposed of in a few words. The literature does not show a case that has been treated for intracranial cephalhæmatoma. The diagnosis has always been made on the post-mortem table. Possibly that horrid instrument the trephine might find here a field for usefulness.

REMARKS ON ABDOMINAL SURGERY, WITH CASES.[1]

By EDWARD BORCK, M.D.,
ST. LOUIS, MO.

At the meeting of the Tri-State Medical Society, held at Evansville, in 1879, I read a paper entitled "Ovarian Tumors: At what Stage of the Disease is it the Proper Time to Operate?" At that time my own experience was very limited, and I had to sustain my views, in favor of early operations, on theoretical grounds, making quotations from and using some statistics of others. However, my paper was followed by a very interesting and instructive discussion. One surgeon remarked that my paper was a good one, containing valuable points and suggestions, but he could not agree with me as to an early operation—he believed in the waiting plan: let the patient live as long as she possibly can, and resort to extirpation only as a last chance. He had lost at least twelve patients in succession.

Another surgeon held the same view, but acknowledged, and to his credit may it be said, that he had lost thirteen patients in succession, and was almost afraid to touch another case; there were others, also, of the same opinion. There was but one surgeon who stated that he always operated as early as he had made a diagnosis, if his patient would let him; he saved about sixty-six per cent. of his cases.

My paper was published in the *Cincinnati Obstetrical Gazette*, March, 1880, but the report of the discussion was omitted.

I still adhere to the views then expressed, in favor of an early operation, and to-day I am able to sustain my former theory by my own practice.

In March, 1878, I had my first case of ovariotomy. The patient was a lady fifty-five years of age, suffering from a multilocular tumor. She lived in the country, and was recommended to me by my neighbor and friend, Dr. G. W. Hall, and I shall be ever thankful to him for his kindness; for if he had not sent me this case, I might never have had the others. Previous to this time I knew nothing about the operation, and very little of the disease, having had but little opportunity to observe such cases, and never having seen the operation performed. My surgical practice ran in another direction. However, I studied the operation as well as I had time to do while the patient was under observation, and made all the necessary preparations. I tried to find a work on ovarian tumors, by either Peaslee, Atlee, or Wells, but none of my acquaintances in St. Louis had either one of them in his library. Dr. Hall advised me to operate under the guidance and with the assistance of one who had had experience in such cases, which wise suggestion I followed, and called upon Dr. Louis Bauer, who cheerfully agreed to aid me with his counsel. Under his protection I operated upon this patient, notwithstanding that all the other surgeons who were consulted advised against the operation, and in favor of the expectant plan. The cyst was only of a few months' duration, in the third stage. I conducted the after-treatment myself; my patient recovered.

Here allow me to relate some of the tribulations I had to endure during the progress of my case; and I will first state that, at that time, the opinion of the profession of my city was almost unanimously for the waiting—the last moment—plan.

[1] Read before the Mississippi Valley Medical Society, at its meeting in Evansville, Ind., September, 1885.

The surgeons in St. Louis prior to 1878 had not been very successful with ovariotomy. The bad results were attributed to the atmosphere—they said that malaria in our climate acted so very detrimentally upon these cases. It was taken for granted that every patient operated upon would die, and every doctor, even those connected with the case, expected that mine would also succumb, and that is the reason why every doctor whom I met would put the polite questions: Is your patient dead? Will she die? How long do you think she will live? Questions framed in that style were the interrogations of all, except of Dr. Alleyne, who in his kind and big heart said, "I hope she will recover;" well, she did, and it was a wonder. Being called an enthusiast, it was said that the success would drive me crazy.

My next case was a lady forty-three years old. I removed a large right ovarian cyst in the last stage, and also removed the uterus; she died. Seventeen years before Dr. Pope had extirpated a cyst of the left side from this patient.

The next case was a young girl, fourteen years old, who suffered from a single cyst of the left side in the last stage; she died.

But we learn something from the cases we lose, and, you may rest assured, I devoted all my spare time to the study of such cases.

I then had eight successful cases in succession. The next case, one of ovarian cyst complicated with cancer, I lost.

The twelve succeeding cases recovered. Then I lost two cases, both of simple cyst in the last stage of the disease.

Out of my following twenty-five cases I lost but one, a colored woman; I diagnosed a cyst of broad ligament, last stage, and recommended tapping; however, it was agreed to operate, and she died.

This gives me fifty cases from March, 1878, to May, 1884, with five deaths, as follows: Simple cysts, 8; cyst of broad ligament, 2; ovarian cyst with cancer, 1; ovarian cyst with removal of uterus, 1; persistent pain of ovary, found on removal to be due to cystic degeneration, 1; fibro-cystic tumors, 6; oligo- and poly-cysts, etc., 31.

These cases were all from private practice, as I am not directly connected with any hospital, nor have or had charge of any hospital where such cases present themselves or could be sent to; they were all, with the exception of one case, operated upon at their own homes, and were distributed over several States. The cases were all, with exceptions of those that died, early operations—from six to twenty-four months' duration; the youngest patient was fourteen years, the oldest sixty years. Twice I used drainage-tubes through the abdomen, and once drainage through the vagina, in cases in which there were many adhesions and consequent surface bleeding. In all the other cases the abdomen was closed; the pedicle was dropped into the abdomen in every case. In one case, a simple cyst, I had to open the abdomen again on the third day, as my patient was sinking from internal hemorrhage; I washed out the clotted blood and closed the wound again. She recovered. In this case I had been induced to employ the catgut ligature. I will never use it again.

After my first case I adopted one mode of operating, which, with the exception of lately discarding the spray, I have strictly adhered to in every instance, and with which you are all acquainted.

I remain with my patients until they are out of danger—sometimes from three to six days.

What influence the atmosphere and the malaria of Missouri and vicinity have had upon such patients I am not able to say at present, for other surgeons of my city and elsewhere have also had brilliant success of late. It may be that the air, so detrimental previous to 1878, has since changed for the better.

Now, when we know that the average life of a patient afflicted with ovarian tumor is four years; that polycysts terminate fatally in twelve months, oligocysts in twenty-four months, after the third stage has begun—what conclusions can be drawn from my own cases?

1. That those cases operated upon in the very last stage died.

2. That the comparatively early operations were successful.

3. That there is no absolute need to send your patient off to a hospital or private institution if she is moderately comfortable at home. I always advise those gentlemen who attend my lectures, as well as others, to do as I do—take care of their own patients, if they have the confidence in themselves to do so; but if you do, by all means give your patient all your time and attention, and be well prepared for all emergencies.

For one class of patients the hospital may be indicated; for another class of patients a private institution may be preferable, or more convenient for the surgeon; nay, it may become a necessity for him who has more than one case—it saves time and labor; for I know what it is to travel fifty, one hundred, or five hundred miles to see your patient, and prepare for an operation, and give her your exclusive time. It has been intimated to me more than once that I must pick my patients. I will freely and openly admit that I do, and I will tell you how I do it. If a case of fibrous tumor of the uterus presents itself, and the patient is fairly comfortable, age about forty-three or forty-five, I advise her to wait and not interfere by operation—such are cases for the waiting plan; for we know that if she passes her menstrual period she has a chance to recover; at least her misery will cease, and if the tumor does not shrink, it will at least cease growing. If she still insists upon the operation, I refuse, and advise her to obtain the opinion of some one else. I know that some of such refused patients have been operated upon by others, and they have died. If others present themselves with tumors in the last stage, with broken-down constitutions, and with the chances all against them, I give them no encouragement whatsoever, and they will of their own accord seek other advice.

The favorable cases, of course, I encourage; but I never urge the operation. I leave that to the patient to do. Again, I see a patient where a certain something (call it, if you will, the faculty of presaging) tells me that the result will, or may be, fatal; then I had rather not have the patient. I must feel that my patient will survive, and so must she—there must be the utmost confidence on both sides.

I am never anxious for a case; I am never anxious to operate for the sake of the operation. On the other hand, I would not refuse a case, even the most desperate one, if the operation offered the only, even the slightest, chance of saving her life. Here moral duty would commend the surgeon to run any amount of risk.

I will relate a case which I saw in Illinois some time ago, one of ovarian cyst in the last stage, complicated with extra-uterine pregnancy. The woman suffered dreadfully, she was a pitiful object to look at, and certainly doomed to death. Had I been prepared I would have operated at once, as she was willing; the next day was Sunday, and she would not be operated upon on that day. It was put off until Monday morning; but the patient did not live until then. Sunday the tumor broke through the vagina, and she died at once. In such a case I think it would have been perfectly justifiable, at least to try and give relief.

My intention was to relate all my cases in detail, but I think now that such is not necessary; for, even after one has gone through the labor of preparing a long list of cases and their histories, very few will read them, far less study them. We are well enough supplied with the reports of isolated successful cases. You can hardly take up a journal, wherever published, that does not contain the report of a case. They are of no value in a statistical sense, but it speaks well for the American pro-

fession that there are men, even in the smallest towns, capable of performing any operation, and ready to do their duty. In the near future this will be considered a minor operation. But is it not reasonable to suppose that wherever there are successful cases there may also have been failures? How few of those isolated fatal cases do we see reported!

I have seen many operations abroad and at home. Of the home cases in which I have seen others operate the majority died. Not a single one of these cases has been reported up to the present time. Well, my friends may say I picked my cases; I would call it a judicious selection or discrimination between cases, and recommend all who begin to do the same. One thing my friends cannot say: that I hide my fatal cases. Every one of my fatal cases has been published at once and in detail, and I will publish every other case I happen to lose in the future, for the benefit of all. I keep full records of all my cases, and some day, when their number has doubled, I may have them published.

Since 1878 I have seen and examined on an average about twenty-five cases per year for abdominal enlargement, and in not a single instance have I made an exploratory incision for the purpose of making a diagnosis, though it is justifiable in very doubtful cases, and, as a rule, safe.

I do not believe in the practice of opening every woman's abdomen because it is easier to make a diagnosis. I prefer the more difficult manner—without the knife; but whenever I might be in doubt, and should have to resort to an exploratory incision, it would be with the distinct understanding to go on with the operation at once if such were indicated.

Clinical Department.

A HUGE DOSE OF PEPSINE.

Dr. W. H. Rassman, of 219 East Forty-eighth Street, relates a case of poisoning by pepsine. The patient was a man suffering from dyspepsia, for whom he had prescribed five drachms of pepsine to be made into twenty powders, one to be taken after each meal and to be followed by a dose of hydrochloric acid. The patient was of a practical turn of mind, and, having read somewhere that pepsine was inert, determined to test the matter himself. Accordingly he emptied the powders into one mass and swallowed the entire five drachms. This was done in the evening, shortly before retiring. In about an hour he was seized with an intense burning pain in the epigastrium, accompanied by nausea, and three hours later with violent colicky pains and diarrhœa. These symptoms continued until nearly noon of the following day, when they disappeared, leaving only a moderate amount of nausea, burning in the epigastrium, and a feeling of exhaustion. There was no vomiting. Dr. Rassman did not see his patient until after he had recovered, and nothing had been taken to counteract the effects of the drug. The pepsine had been procured from a reliable apothecary, and there was no reason to suspect that it was not pure and of full strength. The solution of hydrochloric acid was not touched.

THE HEALTHFUL EFFECTS OF ALCOHOL UPON THE LIVER.

Dr. C. C. Duffy, of 263 West Fifty-fourth Street, writes concerning the good effects upon the hepatic circulation of alcoholic stimulants. The value of alcohol, he says, is best seen in persons who have passed through what might be called the sthenic stage of malaria, and have entered into the asthenic period. "In this state the constitution is so broken down as not to furnish sufficient caloric to resist the effects of the vicissitudes o the weather upon the circulation, a derangement of which produces a congestion of the liver and causes an interruption of its functions. Persons in this stage of malaria are always anæmic, and suffer cold even when warmly clad and during the heats of summer. Quinine, iron, strychnine, and phosphorus are all good for such cases in minute doses, but they do not furnish the great desideratum, heat. By the use of alcoholic liquors we can create an artificial heat by stimulating the circulation. If this be accomplished we dispel those congestions which always follow a disturbance of the circulation, and the liver, now not overburdened with too much blood, performs its functions as in health. The alcohol, in these cases, is not to be prescribed in regular doses, but should be taken in such quantities and at such times as will suffice to produce the desired effect."

Progress of Medical Science.

On the Significance of Osseous Lesions in the Diagnosis and Treatment of Inherited Syphilis.—A paper on this subject by Dr. R. Lomer, of Berlin, appears in the *Zeitschrift für Geburtshülfe und Gynäkologie* (Band x., Heft 2). It refers to the disease of the bones described by Wegner. Dr. Lomer holds that the presence of these changes in a well-marked form is proof of syphilis; and applying this test, comes to the conclusion that the large majority of cases of premature labor are due to this disease. General practitioners, in Dr. Lomer's opinion, know very little about these bone lesions. They are to be demonstrated by exposing the femur and making a longitudinal section of it. In a healthy bone, the junction of cartilage and bone is a simple line, either straight or undulating, but sharp and well defined. In a syphilitic bone it is a broad layer, from which irregular processes project into the cartilage. The epiphysis is either quite loosened, or there are deep fissures in the bone below the line of ossification. In some cases these changes can be easily seen with the naked eye, but in others they may be so slight as to need microscopical examination of carefully prepared sections. Although this disease indicates syphilis, yet a normal condition of the bones is not proof of the absence of syphilis. Dr. Lomer puts before his readers the following generalizations, based on the examination of forty-three fœtuses which had died in utero. When the bone disease is well marked, the liver and spleen are abnormally large. It makes no difference in the degree of the changes present, whether the syphilis is derived from one or both parents, whether in the parent the disease is one year old or ten, whether secondary symptoms have persisted or not, whether the parent has been treated or not, or whether the child be large or small. Syphilitic fœtuses differ in appearance from non-syphilitic. The latter are brown and mummified, the former flesh-colored and more œdematous. In the non-syphilitic the mother can commonly assign a date for the infant's death, and the weight of the fœtus corresponds to the period indicated by her statement. This is not the case with the syphilitic; and in them the placenta is commonly unusually heavy in proportion to the weight of the fœtus.—*British Medical Journal.*

The Nature and Treatment of Sea-sickness.—At the last meeting of the Berlin Medical Society, in July, Dr. R. Neuhauss read an article on an old subject, which, however, he presented in a somewhat new light. He desired, he said, to correct the common error of associating sea-sickness and vomiting. The latter was, it was true, a prominent and nearly constant symptom, but it was nevertheless but one of a number of symptoms. These are very decided malaise, loss of appetite, dizziness, great prostration even to apathy, slowed heart-action, dull, boring, usually unilateral headache, obstinate constipation and lowered functional activity of the kid-

neys. In their relations to sea-sickness men may be divided into three categories: The first group comprises those who never suffer from the malady; these are, at the highest estimate, not more than three per cent. of all who sail the seas. Another group embraces those who suffer constantly and never lose their susceptibility; these are also about three per cent. of the total number. Finally, there are those who are ill for some days on commencing a voyage, but who later become accustomed to the motion of the vessel and recover from the affection caused thereby. Many of the symptoms are explained by the changing intracranial blood-pressure caused by the vessel's motion. When going down into the trough of the sea, hyperæmia of the brain is produced, and in rising upon the wave, anæmia occurs. It is well known that nausea and vomiting follow upon any sudden diminution in the amount of blood within the cranium. During a recent voyage, the author said, he had discovered that the secretion of the kidneys was markedly reduced in a storm, when the movements of the ship were violent and long-continued. A consideration of this fact, which he established by actual measurement, led Dr. Neuhauss to the supposition that the dull, boring headache and apathy experienced after a long continuance of sea-sickness, were really a mild form of uræmia. Much amelioration, and even complete cure, might be obtained by lying down "all in a heap," with the hips and knees flexed and the head bent forward on the chest. In this way the vessels are made more tortuous, and there is less of a tide in the cranial circulation in consequence. There is also less tossing about of the abdominal organs, upon which some of the symptoms, notably those caused by irritation of the vagus, depend. Chloral hydrate is a valuable drug in sea-sickness. It may be given in doses of fifteen grains, not at the commencement, but on the third or fourth day of the disease. Other drugs the author regarded as useless, and spirits he thought were positively harmful.—*Allgemeine Wiener Medizinische Zeitung*, August 4, 1885.

Supplementary Spleen.—Mr. S. H. Peevor reports in the Indiana *Medical Gazette* for July, 1885, a case of supplementary spleen which he discovered in making an autopsy upon a native woman, supposed to have been poisoned. The natural spleen was enlarged to twice the normal size, but was healthy in other respects. The additional spleen was almost spherical, about one inch in diameter, and about one inch distant from the hilum of the natural spleen, which it was connected with by two or three narrow, white, fibrous bands. It was attached to the omentum, and its structure appeared to be that of a normal spleen.

The Pathology of Wry-Neck.—Since subcutaneous myotomy did not always produce the desired result, Volkmann has been led to open the sheath of the muscle and divide it by an open section. He has performed this operation a number of times in late years, and has thus had many opportunities of examining the muscle microscopically. In several cases this was perfectly normal, but in others the muscle was entirely absent and was replaced by a mass of fibrous tissue. The most common condition was one between these extremes. The author believes, as a result of his studies, that, while tearing of the sterno-cleido-mastoid at birth is by no means the only, or the chief, cause of caput obstipum, it can, nevertheless, not be excluded wholly as an etiological factor in the production of the deformity—*Centralblatt für Chirurgie*, No. 14, 1885.

Scarlatiniform Rash Produced by Intestinal Absorption of Ptomaines.—A patient observed by MM. Lépine and Molière presented at first nothing abnormal, except an artificial anus, the consequence of a strangulated hernia. One day he was suddenly seized with violent delirium, and M. Mollière noticed a considerable dilatation of the pupils. The skin was covered with a scarlatiniform rash, but there was neither fever nor angina. Poisoning by belladonna was at first suspected; but, after a careful examination, M. Lépine came to the conclusion that the symptoms were due to the absorption by the intestine of ptomaine, acting like atropine, and probably similar to that obtained by Zeulzer and Sonnenschein from putrid substances. After a short time acute conjunctivitis and fever supervened, and the patient died. At the post-mortem examination a highly-offensive substance was found in the intestine below the artificial anus, so that the possibility of an acute auto-intoxication cannot be disputed.—*British Medical Journal*, August 22, 1885.

Antipyrine in Acute Pneumonia in Children.—Dr. Arzutenky reports a number of cases of acute lobar pneumonia in children of four to eight years treated successfully by antipyrine. Ordinarily there was a reduction of temperature of 3° or 4° F. within three hours. In rare instances the temperature fell below the normal, but without, however, any symptoms of collapse. After a time the temperature rose again, but gradually and not with rapidity. The pulse did not always fall in proportion to the temperature. The author gave the drug three times a day in doses of three grains for an infant one year old, six grains for children from four to five years of age, and nine grains for those between ten and twelve years. Although the daily average temperature was reduced 2° or 3°, the proportion between the morning and evening variations remained about the same—*Revue de Médecine*, August 8, 1885.

Neuroses of the Stomach.—Dr. Oser divides the neuroses of the stomach into two classes, according as they depend upon a diminution or increase of muscular power in the organ. In the first group he notes: 1. Rumination, which results probably from a paralysis of the cardia. The mild forms may be cured by the avoidance of all liquid food, lying down upon the back after eating, and faradization of the cardia. The grave forms terminate fatally. 2. Pyloric insufficiency. For this the author advises distention of the stomach by carbonic acid. 3. Gastroplegia, or muscular weakness of the organ. In the second group are: 1. Spasm of the cardia, which may be diagnosed by the œsophageal bougie. 2. Spasm of the pylorus, which is due to reflex action caused by fissures. 3. General gastric spasm (the author does not say to what this is to be referred). 4. Peristaltic derangements, which are frequent in neurasthenia and hysteria. 5. Nervous vomiting.—*Revue de Médecine*, No. 32, 1885.

Acute Primary Tuberculosis of the Spleen.—Dr. J. Icharold relates the case of a young man twenty-five years of age, who was seized with a chill and a violent headache followed by heat and sweating. On auscultation numerous fine râles were heard, and percussion revealed an enlargement of the spleen. No other lesions were revealed by physical examination. There followed cyanosis, epistaxis, diarrhœa, and a slight degree of albuminuria; later delirium, and finally death on the eighteenth day. At the autopsy the spleen was seen to be markedly hypertrophied (three times its normal size), and it was filled with miliary tubercles. There was also some tumefaction of the solitary intestinal follicles and of Peyer's patches; but there were no signs of tubercles in the meninges, peritoneum, or lungs.—*Lyon Médical*, August 9, 1885.

Subcutaneous Ligature of the Brachial Artery.—Dr. Raimondo Cannizzaro, being called upon to ligate the brachial on account of a wound involving the radial and ulnar branches, made a valvular opening by drawing the skin tight, tied the artery with carbolized silk, and allowed the skin to slip back covering the wound. The superficial wound healed by first intention, and in seven days the patient left the hospital cured.—*Revue de Chirurgie*, August 10, 1885.

Iodide of Potash in the Treatment of Psoriasis.—Dr. Hashurd reports a number of cases of psoriasis treated with iodide of potassium alone (*Hospitals-Tidende*, No. 17, 1885). In two-thirds of the cases in which the treatment was faithfully carried out a cure resulted; in the remaining third no improvement followed. The drug was given in very large doses, as much as eight or ten drachms a day, and continued for six or eight weeks. In one case the patient consumed between thirty and forty ounces of the iodide during the course of treatment. In only one instance were any of the characteristic symptoms of iodism manifested.

Iodoform in the Treatment of Tubercular Meningitis.—Dr. Emil Nilsson reports, in *Hygiea* for July, 1885, three cases of tubercular meningitis occurring in one family. The first two children were treated in the usual way and died. Not long after the death of the second child a third one, a boy eight years old, began to grow thin and pale. A few months later he complained of headache and had several convulsions. When seen he lay in a semi-stupor with closed eyes, and could hardly be roused sufficiently to tell where he had pain. Calomel and iodide of potassium were ordered, but were soon discontinued because of the persistent vomiting. The symptoms of tubercular meningitis were well marked, and increased in severity until a fatal termination seemed to be approaching. The hair was then shaved off and an ointment containing ten per cent. of iodoform was smeared over the head and retained by a close-fitting cap of oil-silk. The inunction was repeated three or four times, and the cap was then left on for thirty-eight hours, at the end of which time it was removed and the head washed with soapsuds, alcohol, and vinegar. Within twenty-four hours there was an improvement in the little patient's condition, the muscular twitchings became less noticeable, sleep was more sound, and the restless tossing about in the bed ceased. There were some symptoms of absorption of the iodoform, and the odor of the drug was noticeable in the breath eight days after the cap had been removed. The child is now in perfect health.

Treatment of Erysipelas on the Expectant Plan.—There are numerous methods of treatment of facial erysipelas in vogue, each of which has its special advocates, and is supported by an array of facts showing its curative value. But in any case in which so many diverse plans are brought forward as efficacious in the treatment of a particular disease it is usually safe to assume that the disease is self-limited, and is not controllable by any specific remedy. Some cases reported by Dr. Carmelo Andronico in the *Giornale Internazionale delle Scienze Mediche*, No. 6, 1885, would seem to show that this is true also of facial erysipelas. The author treated fifteen successive cases of this affection, occurring among the inmates of a female penitentiary, on a purely expectant plan, and all recovered. They were of varying degrees of severity, but no remedies were exhibited either externally or internally, with the exception of alcohol. Wine in daily doses of about twelve ounces was given in a few cases in which there was marked delirium. None of the patients died, and all seemed to progress as favorably as, or even more so than those subjected to active medicinal treatment.

The Prophylactic Treatment of Dental Caries.—In an article in the *Independent Practitioner* for August, 1885, Professor W. D. Miller, of Berlin, gives the results of a number of experiments made by him to determine the availability of various antiseptics in the prophylactic treatment of the oral cavity. Since in rinsing the mouth one does not usually keep the fluid in contact with the teeth for more than a minute, an antiseptic mouth-wash to be of use should be capable of devitalizing the fungi of the mouth in one minute or less. Of a number of substances used in the experiments the author found but four which were capable of devitalizing the fungi in the given time. These were bichloride of mercury (1–2,500), benzoic acid (1–100), salicylic acid (1–100), and pure Listerine. Of the four the bichloride was the most effective, as it possesses the advantage of penetrating more deeply into the cavities and between the teeth. It has one disadvantage, however, in its highly poisonous character, and although it is hardly probable that harm could result from its use in so dilute a solution, it nevertheless offers an objection to its use. With regard to salicylic acid it seems to be a question whether it is injurious to the teeth or not, and it should therefore, the author says, be used with caution. Listerine acted with considerable rapidity upon the fungi in the experiments made by the writer, and that substance or benzoic acid would seem to be preferable as a mouth-wash in the prevention of caries, if further experience should demonstrate that they exerted no injurious influence upon the dental substance.

Poisoning by Petroleum.—Dr. Duguet, of the Lariboisière, relates the case of a woman, aged forty-eight, who was brought into that hospital May 8th, having just swallowed about a pint of the ordinary petroleum of commerce with suicidal intentions. She at once felt a strong sensation of oppression along the œsophagus, and especially at the stomach, together with a sense of burning, and was in a very agitated condition. She exhaled a powerful odor of petroleum, and on vomiting being excited by ipecacuanha, with large quantities of milk, a good deal of petroleum floated on the ejections, as it did in those produced from the bowels by a clyster. All the urine of the patient was carefully preserved, and that passed just before the emetic was given contained a floating layer of petroleum, about one inch in thickness. On the day after her admission the floating petroleum in the urine amounted to about five drachms, but by the next day had diminished to one drachm, and then gradually disappeared. Some albumen, which at first was present, disappeared with the petroleum. During the first four days the petroleum prevented the urine from undergoing decomposition for ten days.—*Gazette des Hôpitaux.*

Hernia of the Stomach into the Scrotum.—Dr. Vogt (*La Presse Médicale Belge*) reports the case of a man, sixty years of age, with a scrotal hernia of the size of an adult head, who died in collapse with symptoms of local peritonitis, but without symptoms of strangulation. The autopsy showed, among other things, as a part of the contents of the hernia, the pyloric end of the stomach enormously dilated, the epiplon, the cœcum with the vermiform appendage, the ascending colon, the transverse colon, and the commencement of the descending colon. The stomach had an hourglass dilatation corresponding to the hernial ring; the lesser curvature, a little distorted above, was slightly elongated, while the greater curvature and the body of the organ were outside the ring. The extraordinary dilatation of the stomach had completely changed the relations of the organs in the abdominal cavity, so that the small intestines were carried to the left, and below, into the pelvis, and the liver had been drawn from the right side toward the median line.

Pulmonary Arteritis.—In an elaborate article on this subject, Dr. Rattone (*Archive delle Scienze Mediche*) formulates the following conclusions from a study of upward of fifty cases: (1) Pulmonary arteritis may be either acute or chronic (atheroma), the latter being the more frequent. (2) It may be primary or secondary, the primary form not leading to cirrhosis of the lungs. (3) The cases seen by the author of acute arteritis had their origin from a primary inflammation of the semilunar valves. (4) Chronic inflammation or atheroma may be met with in any portion of the pulmonary artery, but is more often seated in the vessels of medium size, and especially at their points of bifurcation; it is distributed symmetrically in the two lungs. (5) In this disease there may be seen not only the atheromatous patches, but also abscess, ulceration, and in some cases

calcification. (6) Pulmonary atheroma is entirely independent of a similar disease in the aorta; it may coexist with it, may exist without it, and may be absent when the aorta is profoundly diseased. (7) Pulmonary atheroma is met with constantly in mitral stenosis which has occasioned a certain degree of hypertrophy of the right heart; but may also be found with stenosis of the aortic orifice, in cor bovinum and other congenital defects. (8) The disease may occur in young subjects who have never suffered from heart-disease. (9) Atheroma of the pulmonary artery is a frequent cause of hæmoptysis, and may also give rise to thrombosis and hemorrhagic infarction. (10) Finally, as regards the cause of atheroma, the author agrees with Martin, that it is secondary to arteritis of the vasa vasorum.

Arsenic in Lupus Erythematosus.—Mr. Jonathan Hutchinson (*British Medical Journal*) narrates a case in which a gentleman was completely cured of lupus erythematosus by persistently taking five drops of *Liquor arsenicalis*, three times a day, for two years. In March, 1883, the patient suffered from several patches on the face and scalp. In February, 1885, the lupus was quite well. There were left only thin white scars, without any erythema or thickening at their edges. On the sides of the nose these scars were each as large as a shilling, that on the middle of the nose not so big. On the scalp, which was nearly bald, there were several scars as large as the end of one's thumb. The patient took arsenic regularly for fifteen months; he then had a sharp attack of shingles, and left the medicine off for a little time. No local remedy was applied to the patches on the nose while the arsenic was being taken, though a hair-wash had been sometimes used for the head. Mr. Hutchinson considers that the cure was entirely due to the arsenic, and suggests that a more careful administration of this drug should be tried in these cases, which are often only partially cured.

Cerebral Infantile Paralysis.—Dr. Strümpell has described this somewhat neglected disease in an article of which the following is an abstract: *Poliencephalitis acuta* occurs usually before the end of the first year, sometimes indeed in the first weeks of life. It begins acutely without any apparent cause, with fever, vomiting, general convulsions, and unconsciousness. These symptoms disappear as quickly as they began, leaving behind them, as a rule, complete paralysis of one-half of the body, which soon, however, in part disappears. The arm and leg usually remain more or less paralyzed, while the facial muscles are restored, though sometimes there is slight strabismus. In other cases the paralysis is a monoplegia, or a sort of ataxia alone is perceptible. There is never any degenerative atrophy of the muscles, though the growth of the affected limb is retarded. The paralyzed limbs are slightly contracted, and there is an exaggerated tendon reflex. Most of the patients suffer from subsequent epileptic attacks, which may be general or affecting only the paralyzed side. Athetosis is a very frequent accompaniment. In right-sided paralysis the speech is not infrequently affected, and the patients are usually imbecile, though the intelligence may not be weakened. Sensation is unimpaired. The seat of the disease is in the gray cortical substance in the motor region, where in older cases parencephalic lesions are always found. No autopsies have yet been made in the acute stage of the affection. The author remarks on the resemblance to spinal infantile paralysis, and believes that the two affections may be due to the same or similar etiological factors.—*Centralblatt für klinische Medicin.*

The Viscera in Epilepsy.—M. Vulpian (*Progrès Médical*) has communicated the results of certain experiments undertaken with the view of explaining the effects produced upon the action of viscera by epileptic seizures. He has induced fits of this kind in the dog by stimulating certain points of the sigmoid flexure. A few seconds after the convulsion began the heart-beats and the respiratory rhythm became slower, the latter even to absolute cessation, which was ascribed by M. Vulpian to a special excitation of the respiratory centre analogous to that produced by faradization of the central end of the pneumogastric or superior laryngeal nerve. In the dog, also, as in man, there is increase of the salivary secretion during the attacks. The amount of bile excreted is also in excess of the normal, while the passage of urine, on the contrary, is arrested. In a curarized animal it is possible to provoke epileptic attacks, which are limited in their manifestations to the internal organs. The phenomena then apparent do not differ from those observed in the same regions during ordinary attacks of epilepsy. After the paralysis of the motor nerves of the voluntary muscles the effects of stimulation of the nervous centres continue to travel along the still available visceral nerves, and to give rise to modifications of heart action, contractions or dilatations of vessels and of the pupils, contractions of the intestine and bladder, alterations of secretion, and the like.

Lateral Incision for the Prevention of Rupture of the Perineum.—Drs. Credé and Colpé, in the *Archiv für Gynäkologie*, discuss the practice of incising the perineum laterally in order to prevent its tearing centrally. The objections brought against it are these: (1) That the incision becomes an ulcer, and disturbs the healthy course of the lying-in. This they prevent by bringing the edges of the incision together by suture, with the result that primary union almost invariably follows. They have devised an ingenious method for applying this suture, but without the assistance of diagrams it is difficult to make this understood; we must therefore refer our readers to the paper, where they will find illustrations that make it perfectly clear. (2) That germs of disease may enter through the wound. In this respect the prospect is no worse than that from a torn perineum. Injury to the perineum only to a slightly appreciable extent increases the lying-in woman's chance of disease or death. Out of 2,000 deliveries in Leipzig, among those with uninjured perineums the death-rate was .954 and the morbility 2.94 per cent.; among those with torn perineums the mortality was .934 and the morbility 3.24 per cent. (3) That the incisions do not invariably prevent perineal rupture. To meet this the authors give a table of the percentage of cases in which lateral incisions were made, and of those in which rupture of the perineum occurred, in the practice of five different assistant physicians; and the table shows that the frequency of incision and the frequency of rupture stood in inverse proportion to one another. They also state that since incision has been practised, not a single case of complete perineal rupture has occurred. (4) That the cutting is painful; to which the authors reply, that it is done when the patient is already in much pain, so that she does not notice it. (5) That it leads to subsequent gaping of the vulva. This our authors deny. They believe, in short, that the lateral incision is extremely useful and absolutely harmless. We may add, in order to give an idea of their practice, that in primiparæ, lateral incision was practised in 25.9 per cent., spontaneous rupture took place in 10.4 per cent., and rupture in spite of incision in 2.9 per cent. In multiparæ, the corresponding figures are: lateral incision, 1.2 per cent.; spontaneous rupture, 2.4 per cent. They give figures also which show the influence of perineal ruptures in causing illness during the lying-in period. The percentage of primiparæ whom it was necessary to keep in the hospital longer than a fortnight, was 23.1 among those with perineal cuts or tears, 11.4 among those in whom the perineum was uninjured. In multiparæ it was only 6.8 per cent. The authors recommend that the incision should be made just after the acme of a pain, *i.e.*, just as it is beginning to pass off.

Dust Beef is what an Italian manufacturing firm calls its new, and, of course, improved form of beef-powder.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, September 26, 1885.

THE DANGER OF CONSANGUINEOUS MARRIAGES.

THERE is no subject with regard to which statistical inquiries have furnished more contradictory results than that of the effects of consanguineous marriages. The general opinion, supported by social usage, religious belief, and even legislative enactment, is that such marriages entail almost always certain dangers. These dangers are various degenerative disorders, such, in particular, as idiocy, insanity, deaf-mutism, and, most of all, according to Dr. Devay, a specific taint which causes sterility in the offspring of these marriages. Dr. Bemiss, Dr. Howe, Dr. Arthur Mitchell, MM. Cadiot, Devay, Boudin, and Lasègue have published statistics showing the evil effects of these marriages; while MM. Bourgeois, Seguin, Dally, Voisin, and recently Dr. Charles F. Worthington, of Boston, give facts which seem to bear with equal or greater force in the opposite direction. Dr. Huth, in his elaborate work on "The Marriage of Near Kin," has also collected many statistics for and against the harmlessness of consanguineous marriages. Impressed with the untrustworthiness of much of the statistical data at hand, Dr. Worthington, of Roxbury, Mass., has taken the pains to study the subject anew, and to collect more complete histories of cases than has heretofore been done. It is very well known that the same circumstances and environment which lead isolated communities to intermarry, and thus furnish facts for the pessimistic statistician, may tend to produce the very diseases which are attributed to the too close mingling of blood.

Dr. Worthington collects the histories of one hundred and eight marriages. In eighty-six of these the relationship was that of first cousin; in four, first cousins once removed; in one, third cousins; in one, cousins, degree not specified; in one, uncle and niece; in two, brother and sister. All of these unions, save five, were fertile; the number of children being quite up to the average, viz., five. The children of these consanguineous marriages themselves married and had an average of over five children for each union, thus showing that neither directly nor indirectly did these marriages of near kin cause sterility. Out of a total of 413 children, the offspring of consanguineous marriages, about seventy-five per cent. (312) were reported healthy. Among the 101 unhealthy children the prevailing troubles were deaf-mutism (12 cases), insanity and idiocy (7 and 13 cases); while 15 died of phthisis, 16 died in infancy, 6 were "not robust," and 1 was epileptic.

It cannot be denied that twenty-five per cent. is a rather abnormal proportion of unhealthfulness, the ratio of idiocy and deaf-mutism being especially large. Dr. Worthington adduces facts, however, which show that these conditions might be, and in many cases certainly were, due to a special morbid inheritance with which the marriage had nothing to do.

The facts presented show that consanguineous marriages are, in the majority of cases, perfectly harmless and carry no specific taint to the children. It cannot be doubted, however, that if there is any morbid tendency in either parent, there is great danger of its being intensified in the children. This is the conclusion reached also by breeders. One alliance of blood relations may be perfectly harmless, or even beneficial, but if kept up, it is sure to produce deterioration. Now since it is often so difficult to say absolutely that an individual has no morbid taint, it follows that we must, despite favorable statistics, cling to the present view that consanguineous marriages are a source of danger. In other words, two cousins who are apparently healthy have a slightly greater chance of having children with some degenerative taint than two apparently sound persons who are not related.

THE RADICAL TREATMENT OF THE DISEASED CERVIX UTERI.

THE true centre of the gynecological system is probably the cervix uteri. From it radiate the innumerable pains and irritations, and out of it drip the succulent secretions which develop into overshadowing magnificence the science of the pathological woman. Imagination quite fails in any attempt to estimate the amount of laborious thought and ingenious investigation which this little organ has called forth. The cervix uteri seems to be of comparatively little use to woman, but it has been an immense stimulus to man. Yet we can hardly say that he has even now entirely mastered it. There is certainly nothing that therapeutical enthusiasm put to its tensest strain could devise with which this little organ has not been conscientiously bombarded. But it still will keep red, secretive, tender, and ectropic.

It cannot be, however, but that the intellect of man, with its four extra ounces of encephalic substratum, will in time overcome the ounce of perverse flesh which drags down so many of the gentler sex.

We observe, in the New York *Medical Journal* for June 27th and July 4th, an article which appears to point a way toward such a supreme triumph. Dr. Simon Baruch, the author of the article in question, calls attention to certain facts in the physiological and pathological history of the cervix which he thinks have not yet been sufficiently appreciated. These are that the cervix uteri is really a "vast gland;" that it has a mucous lining full of intricate windings and furrows, and containing an enormous gland-supply hidden beneath it and penetrating to a considerable depth into the connective-tissue. This glandular structure is not reached in the ordinary topical applications to the cervix, hence no effective treatment results. To secure success these glands must

be laid open, curetted, and the reagents applied directly to the diseased tissue. This view is rational, and quite in accordance with the most fundamental rule in the treatment of diseased surfaces. In laceration of the cervix, also, when a condition calling for an operation exists, one of the most important things indicated is a removal of the diseased and hyperplastic tissue.

Such removal of diseased cervical tissue is also believed to have an important influence in preventing the development of cancer. This assertion, which is based upon sound reasoning from the known facts of pathology, deserves careful attention from physicians who have the care of, but are not treating, patients with chronic inflamed and lacerated cervices.

Dr. Baruch summarizes his views as follows: "1. A thorough knowledge of the anatomy, physiology, and pathology of the cervical follicles will simplify the treatment of many uterine affections. 2. The cervix uteri represents a large gland of active and important function in the various sexual relations of woman. 3. In the majority of the more common diseases of the uterus the mucous membrane and its follicles play the most important rôle. A recognition of this fact will make treatment more successful. 4. Metritis, subinvolution, hyperplasia with catarrh, erosions, etc., must be studied in connection with the glands of the cervix. 5. In obstinate cases medicinal applications fail because the secreting surfaces of the follicles are not reached. Scarification and the curette are valuable adjuncts in nulliparous women, or in parous women without cervix laceration. 6. In parous women with laceration, trachelorraphy is the most valuable procedure. As a simple plastic operation it will fail. Success depends on extirpation of the follicles, which is more important than removal of the cicatricial plug. 7. The microscope demonstrates the dependence of catarrh, ulceration, erosion, and hypertrophy of the cervix, and often also of the body of the uterus, upon the glandular structure of the cervix uteri. 8. The cervical follicles are significant as elements in the pathology of cervix cancer, because the microscope demonstrates the dependence of the latter upon erosions which are based upon the gland structure. 9. Laceration and erosion must be regarded with suspicion, as possible sources of future malignant disease. In operating for their removal, extirpation of the cervical follicles must be unsparing."

A NEW THERAPEUTIC PRINCIPLE IN THE USE OF MINERAL WATERS.

The chemical composition and the therapeutic action of mineral waters have engaged the attention of physicians for a long time. That mineral waters are efficacious in the treatment of certain classes of affections is well established, especially those which are benefited by influencing the mucous membrane of the alimentary canal.

Recently Sydney Ringer, of London, and Dr. Hayes, of Aberdeen, have emphasized the important influence which the chlorides exert in accelerating intestinal action, and thus far have confirmed the earlier experiments of von Voit with reference to the influence of the chlorides, especially the sodium chloride, on the oxidation of albumen and the consequent increased formation and elimination of urea.

Mineral waters have of late years been used largely as saline purgatives, depending chiefly upon the use of those especially rich in sulphate of soda and magnesia. But von Mering, Frerichs, and Henry Thompson have for a long time urged that it was important to distinguish between those waters which are promptly purgative and those which contain a large combination of the *chlorides* of sodium and magnesium. Frerichs, especially on clinical grounds, has pointed out that in prescribing purgative waters it is well to have a more careful regard to their differences in chemical composition and their consequent different effects. If, he says, it is merely desired by increasing the secretion of the intestinal glands to render the contents of the intestines more fluid, and to evacuate them, all the aperient waters are more or less useful, according to the quantity of purgative salts they contain; but their continuous use, he adds, interferes with the process of digestion, and thus affects the general health. The effect, however, he says, is very different when, besides the sulphate of soda and magnesia, large quantities of the chloride of sodium are present, as in some of the more noted mineral waters, for then we have the favorable influence of the chloride upon digestion and tissue-changes generally. Sir Henry Thompson has long advocated the use of a mineral water rich in chlorides as well as in sulphates. In his lectures he gives the results of experiments with natural and artificial compounds based upon this principle, and reaches the conclusion that in the natural mineral water, rich in chlorides as well as sulphates, the dose may be continuously diminished, and prolonged treatment is unattended with the exhausting and irritating effects following the use of waters which contain especially large quantities of sulphate of soda. Here, then, chemical research and clinical experience harmonize, and physicians are coming to regard this old therapeutic agent among the large number of mineral waters as especially suitable for prolonged use, when taken, as it now can be, in its undiluted and natural state.

THE SIXTH VOLUME OF THE INDEX CATALOGUE.

The "Sixth Volume of the Index Catalogue of the Library of the Surgeon-general's Office" has been published. It includes references from Heastie to Insfeldt. The herculean labor of its compilation can be reasonably estimated when it is understood that the volume is made up of seven thousand nine hundred authorities, representing two thousand five hundred and forty-three volumes, and seven thousand two hundred and fifty pamphlets. It also represents fourteen thousand five hundred and ninety subject-titles of separate books and pamphlets, and thirty-five thousand two hundred and ninety titles of articles in periodicals. The particularly interesting parts of the bibliography are those referring to hereditary, hernia, hip-joint disease, homœopathy, hooping-cough, hospitals, humerus, hydrocele, hydrocephalus, hydrothorax, and insanity.

Dr. J. S. Billings, the talented librarian, still has his name upon the title-page and may he be spared to complete a work, the like of which has never before been undertaken.

Dr. George W. Fish, United States Consul at Tunis from 1878 to 1882, died at his home, in Flint, Mich., on September 20th, aged sixty-nine years.

News of the Week.

A Change in the Mode of Discharging Lunatics from Asylums.—The authorities have decided that the city shall no longer be burdened with the costs of proving to be insane persons whose release from the municipal lunatic asylums is sought by their relatives, or by petty lawyers desirous to acquire notoriety. Hitherto it has been the custom to make returns to writs of habeas corpus in such cases, in accordance with the statements of the medical officers in charge of the asylums. As those statements were invariably that the persons whose release was sought were insane, issues were raised that had to be tried. These trials were annoying and expensive. The purpose of the Corporation Counsel is hereafter to make returns in such cases, merely setting up that the persons indicted in the writs are held by the Commissioners of Charities and Correction because they were committed to them as insane, and because the Medical Superintendent of the New York City Asylum had not given certificates that they were fit to be at large. By this course it will fall upon the courts to ascertain, in some way satisfactory to them and inexpensive to the city, whether the persons under restraint are sane or insane.

Death of Dr. William Charles Hunter.—We regret to announce the death, on the 20th inst., of Dr. William Charles Hunter, of this city, in the fifty-sixth year of his age. Dr. Hunter was born at Burke, N. H., and was graduated at the New York College of Physicians and Surgeons in 1857. He was once Demonstrator of Anatomy in the medical department of Dartmouth College, with Dr. E. R. Peaslee. He was the author of many papers in medical journals. He was a member of the Academy of Medicine, the County Medical Society, and the New York Pathological Society, and an officer of the Society for the Relief of the Widows and Orphans of Medical Men. Dr. Hunter's health had begun to fail several years ago, and lately he had suffered from renal and cardiac troubles.

The Resources of the Druggist.—Druggists average from $5 to $15 per month from each moderately large family in this city.

Doctors' Endorsements of Tradesmen.—"A writer in an American contemporary, the *New England Medical Monthly*, deplores the debasement of the literature of circulars by the names and addresses of prominent New York physicians which are now printed on carpenters' and plumbers' circulars as advertisements. Since literary enterprise has stooped to tradesmen's handbills, we would suggest as the next step—their tools."—*Medical Press and Circular.* Our esteemed English contemporary is very quick to pick up an item that reflects on the American profession, even if it comes from some irresponsible penny-a-liner. The "debasement" referred to is certainly of very small extent, and would hardly be discovered except by a most industrious garbage-hunter.

The Ovariotomy Record "Broken."—Mr. Lawson Tait reports in the *Provincial Medical Journal* a series of one hundred and twelve operations for ovarian and parovarian cysts, without a death. These operations were performed between January 1, 1884 and August 5, 1885. All the operations were completed. They were performed without Listerism; and this settles, forever, for Mr. Tait, the question as to the utility of Listerism.

International Medical Congress.—On receiving notice of his appointment as one of the secretaries of the Section on Laryngology, Dr. E. Fletcher Ingals declined, on the ground that lack of harmony in the profession make the duties too burdensome. The following additional resignations have been announced: Dr. John C. Dalton, New York, President Section of Physiology; Dr. E. L. Shurley, of Detroit, Council of Section on Laryngology; Dr. Thomas M. Markoe, New York, and Dr. T. A. McGraw, of Detroit, Council of Section on Surgery; Dr. Wm. H. Welch, of Baltimore, Secretary Section on Pathology; Dr. Thomas T. Sabine, New York, Council of Section on Anatomy; Dr. E. G. Loring, New York, Council of Section on Ophthalmology.

Death of a Medical Editor.—We learn with regret of the recent death of Dr. Paul Boerner, of Berlin, at the age of fifty-seven years. Dr. Boerner was editor of the *Deutsche Medizinische Wochenschrift*, one of the leading German medical weeklies.

A Western View of the International Congress.—Our European brethren may perhaps appreciate the fact that the American Medical Association, in its action regarding the Congress, has not voiced the sentiments of either the majority or the best of the members of the profession in America, but we are none the less disgraced in their opinion. It is perhaps wrong to lay this trouble at the door of the Association as a whole, for, as in every other organization of a similar character, it will be found that the active management is in the hands of a very few individuals; but as the matter now stands there is nothing else to bear the responsibility of the family quarrel. With all respect to its venerable editor, the *Journal of the American Medical Association* appears to be the only obstacle in the way of an amicable rearrangement of the committees, and a resumption of the strictly scientific work, which, if undisturbed, will make the coming Congress fully as successful as any of those which have preceded it. Pertinacity is an excellent quality under exceptional circumstances, but in the present instance, concessions for harmony's sake would be in much better taste.—*Western Medical Reporter.*

Chicago Physicians and the Congress.—The International Congress, from the standpoint of the profession here, has a gloomy outlook. We cannot see how, from the present situation, the gathering can be in any sense international. There may be a large meeting, but if only American doctors attend, and if, as the prospect is certain, many of the most distinguished members of our profession are absent, what is the use of a Congress at all! Drs. Lyman, Hyde, Jackson, Parkes, and Senn have publicly announced that under the present organization they *could not* serve in the positions to which they have been appointed. Not only have a large number of the strongest men in the country declined to participate, but so large a class that the idea is growing among the profession here that the Congress will not be worth

attending, that it is a foredoomed failure as an international gathering. This feeling is heightened by the indications from abroad of a growing sentiment of dissatisfaction with our ways of doing, which is entertained by the profession of Europe, and which promises to reduce to zero the small delegation of eminent visitors we had any reason to expect under the most favorable auspices.—*Chicago Cor. of Boston Medical and Surgical Journal.*

The Cook County (Ill.) Insane Asylum—Dr. Spray, formerly superintendent of this asylum, has been re-elected. Dr. James G. Kiernan, whom he succeeds, attempted to introduce some reforms, but he seems to have lacked the tact or executive capacity to accomplish anything. The institution appears to be run for the benefit, not of the lunatics, but of "the boys."

Dr. Bradley Released.—Dr. Bradley, of Birmington, England, who will be remembered as the victim of a charge of criminal assault by a hysterical female whom he was so unfortunate as to attend and to be left alone with for a short time, has, after seven months' imprisonment, been released by order of the Home Secretary. The judge (Lord Coleridge) who tried the case is said to have expressed himself as convinced of the injustice of the verdict rendered. A testimonial is being subscribed to for the pecuniary relief of, and to express the professional sympathy for, the unfortunate physician.

A Writer on Medical Education, commenting on the popular interest in medical topics fostered by medical bulletins from the sick-beds of great men, and especially on the fascination which the germ-theory seems to have for everybody at the present time, remarks that in the wilds of the West a cowboy recently shot another for calling him a d—d microbe.

Another Successful Transplantation of the Rabbit's Eye.—Dr. H. W. Bradford reports in the *Boston Medical and Surgical Journal* a case of enucleation with replacement of the human globe by that of a rabbit. The patient was a seaman, aged thirty-five, with an atrophied globe, the result of an injury in childhood. The result of the operation was fairly successful, the transplanted organ taking up nourishment and establishing a circulation. No attempt was made to secure vision, the object being to obtain cosmetic effects.

Montreal Anti-vaccinationists.—We have received a letter circular which has been widely distributed in Montreal. It consists of a shriek against vaccination in six paragraphs. "Don't permit your precious little ones to be vaccinated! Vaccination is not only unnatural, filthy, and unclean, but positively dangerous to health and life. Scores of children in Montreal have been poisoned with a loathsome disease by vaccination," etc. It is a serious question whether in times of an epidemic society ought not, for its own safety, to suppress such literature.

A Weak Medical Law.—According to the *Call*, a certain Dr. Kellogg was arrested in San Bernardino a few days since for practising without a license. The jury disagreed. He says this is the forty-second time he has been arrested on the same charge, and he has never been convicted.

The Chair of Anatomy in the University of Vermont has, it is reported, been offered to Dr. John B. Deaver, Demonstrator of Anatomy in the University of Pennsylvania.

A Hospital at Dartmouth.—An association has been formed by the Dartmouth College authorities for the purpose of establishing a hospital for those who come to the medical college for treatment, and where students in any department may be cared for when sick.

The Cholera is steadily decreasing in severity in Spain, but is increasing in certain parts of Italy. This is particularly the case in Palermo. Within a week the mortality rose from 3 daily to 185. The inhabitants were seized with a panic and 30,000 fled from the city. About a week ago there was a grand illumination and universal celebration in honor of the appearance of the vision of a saint bearing the assurance that the epidemic would soon disappear. A few days later the people were mobbing the sanitary officers whenever an attempt was made to disinfect places where the disease prevailed.

A New Cancer Cure.—Under this title we mentioned recently, on the authority of one of our exchanges, that Dr. Pampilo, surgeon to St. Peter's Hospital, of Pernambuco, had discovered a new remedy for cancer in the juice of piscidea erithrina. A subscriber in Pernambuco writes us that, with some exceptions this notice is strictly correct. The name should be Numa Pompilio. The bearer of the name is not a surgeon, but a dentist. He is not employed in St. Peter's Hospital, but in the Hospital Dom Pedro II. He did not discover the virtues of the remedy, but was employed by a lawyer of the town to prepare it in a certain way, so as to better preserve it. Finally, piscidia erithrina has never cured cancer.

Keeping out the Cholera.—The Neapolitan authorities are determined at all events to prevent the introduction of cholera from without, however lax they may have been in providing against its spread when once admitted. Dr. Rummo, who had been sent by the government on a scientific mission to Spain, brought back two sealed tubes containing cholerigenous virus, with which he proposed to make some investigations to determine the accuracy of Ferran's methods. The municipal authorities, however, would not allow Dr. Rummo to bring the tubes into the city, and he has therefore gone with them to the island of Asinara, where he will be able to inoculate animals as much as he pleases.

Suicide of a Woman Physician.—Dr. Adelaide Richardson, of Mount Holyoke Seminary, committed suicide last week during a fit of temporary insanity. Dr. Richardson was forty-seven years old. She received her medical education at Ann Arbor, Mich.

A Civil Service Examination will be held in the Post-office Building, on October 1st for applicants for positions as Medical Reviewers and Pension Examiners. Applications must be made to the Secretary of the Civil Service Commission, Washington.

The University of Vienna.—During the summer quarter, just passed, there were 5,122 students at the University of Vienna, 2,310 of which were students of medicine.

Reviews and Notices.

LARYNGOSCOPY AND RHINOSCOPY IN THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NOSE. By PROSSER JAMES, M.D. Fourth Edition, Enlarged, Illustrated with Hand-colored Plates. Pp. 233. New York: William Wood & Co. 1885.

THE author of this little manual has enlarged and revised the present edition. The changes will be found principally in the chapters devoted to rhinoscopy, to diagnosis, and to therapeutics. Motor-laryngeal affections have been more fully considered, but the former classification has been adhered to. The properties and application of cocaine are described. The various apparatus in use are shown in the wood-cuts. An interesting chapter is devoted to the history of laryngoscopy. The general make-up of the book is excellent.

A TEXT-BOOK OF PHYSIOLOGY. By MICHAEL FOSTER, M.A., M.D., F.R.S. Third American from the Fourth and Revised English Edition, with extensive Notes and Additions. By EDWARD T. REICHERT, M.D. With 271 Illustrations. Philadelphia: Lea Brothers & Co. 1885

IN the fourth edition of his Physiology, Professor Foster concluded to place nearly all the reading matter in uniform large type. In the present volume, therefore, we find this plan carried out. It is certainly wiser to place in a text-book only such matter as is worth large type, and the new arrangement is, on the whole, to be commended. Dr. Reichert's additions in histology and critical comment add very much to the value of the work for students.

ELEMENTS OF MODERN MEDICINE. Designed for the Use of Students and Practitioners of Medicine. By R. FRENCH STONE, M.D., Professor of Materia Medica, Therapeutics, and Clinical Medicine in the Central College of Physicians and Surgeons, Indianapolis. New York: D. Appleton & Co., 1, 3, and 5 Bond Street. 1885.

THIS book was evidently bound for pocket use, and contains material on the principles of pathology and therapeutics, and many memoranda and tables for reference; the title-page says "useful memoranda" and "valuable tables." The first fourteen pages exhibit a review of "the recent progress and the present condition of medical science and of medical practice." Here is found a large amount of abstruse indoctrination concerning "molecular mechanism," "physical basis of life," "dependence of the vital processes on oxygenation," "modified cell-life," etc., to which the average medical student and practitioner will take with usual avidity. The remarks with reference to blood letting are not altogether uninteresting, especially in the light of "past experience."

The first *part* is devoted to "General Pathology," including the etiology and anatomical characters of disease, symptoms and signs of disease, modes of examining patients, prognosis and treatment of disease, and "Miscellaneous Topics." Surely the term thus used is very much "congested," as our English brethren say about London Bridge.

Part II. is on Materia Medica and Therapeutics, and while it contains a certain amount of good material, it is sadly in need of a thorough revision. The treatment of "gonorrhœal ophthalmia" consists of a prescription containing sulphate of zinc, sulphate of atropia, carbolic acid, and rose-water, of which "three or four drops" are to be applied "three or four times daily, and also externally with linen cloths." What a method! And it stands without qualification or additional direction.

The treatment for "biliary calculus," recommended as affording the "promptest relief," consists in the use of an enema containing tartar-emetic, tincture of opium, and tepid water; followed immediately by four to eight ounces of olive oil, "taken by the stomach." The *modus operandi* is given as follows: "The opium and tartar-emetic relieve the pain and relax the spasm of the gall-duct, while the efforts of vomiting cause a portion of the oil to come in contact with the roughened surface of the calculi and facilitate their passage." This theory is certainly ingenious.

The author's views concerning fevers must be epitomized: All idiopathic, essential, and non-contagious fevers have a common proximate cause, consisting of the "waste products" which constitute "*the initial factor of the febrile process*," and find their way into the blood and tissues in a state of change or decomposition; this azotized material may originate spontaneously; when retained in the system a sufficient length of time, and in sufficient quantity, "the normal embryonic or *germinal granules of the white blood-corpuscles* become infected by the toxic elements thus engendered." This is a novel way of setting forth a chemical theory.

Under the heading, "Method of Conducting Post-mortem Examinations," the directions for examining the thorax and abdomen lack that definiteness in detail which is so essential to the best aid to those unaccustomed to perform autopsies.

With reference to chloroform the author says: "So far as known, no fatal result has yet occurred from the use of chloroform in *parturition*;" an indescribable bit of ignorance which should never have been allowed to come to the surface. The directions "on the slightest approach of symptoms of heart-failure or asphyxia" are too indefinite, and, so far as faradization is concerned, might with equal chances lead to the death rather than to the resuscitation of the patient.

Speaking of mydriatics, the author says that "from one-sixteenth to one twenty-fourth of a grain of atropine administered hypodermatically will antagonize one grain of morphine." Don't trust it, "it may fool thee;" better study the effects than labor automatically.

What is equally trying, however, is the fact that the directions for "Microscopical Examination of the Urine," down to the words, "or tail attached" (twenty-two lines), are in the identical language used in "THE MEDICAL RECORD Visiting List," and are not included within quotation marks.

For the "Chemical Examination of the Urine" there are only directions for the use of heat, nitric acid, and picric acid, and no mention is made of the recent delicate tests which have been accepted as especially valuable.

"The diseases for which hæmatics are used *originate in the blood*." When was this demonstrated? "*These drugs*"—opium and belladonna—"*acting in an opposite manner on respiration, brain, skin, pupil, and circulation.*" True to only a certain extent, and, therefore, the statement should have been qualified, else harm rather than good may be done.

It is unfortunate that so much good material should be adulterated to the extent it is with unscientific and in some instances dangerous statements.

THE TREATMENT OF OPIUM ADDICTION. By J. B. MATTISON, M.D. Pp. 49. G. P. Putnam's Sons. 1885.

DR. MATTISON'S monograph on this subject is suggestive and interesting. The reader is impressed with the earnestness and conviction with which the writer recommends his methods—evidently the outcome of years of careful observation and study of the opium habit. Dr. Mattison takes strong grounds against the German method (Levinstein's), that of complete and immediate withdrawal. He characterizes it as a "barbarous plan," "positive malpractice," "utterly inexcusable."

He recommends a mean between the extremes of abrupt cessation of the use of the drug, and the very gradual decrease which tends to exhaust the patience of the patient. He relies on bromides, preferably bromide of sodium. He begins with a "preliminary sedative," ob-

tainable in several days. The initial dose is 60 grains twice daily, at intervals of twelve hours, increasing the amount 20 grains each day, and continuing it five to seven days, until reaching a maximum dose of 100 to 120 grains twice in twenty-four hours. In the meantime the opiate is decreased, at first from one-fourth to one-third the usual amount taken daily, and a little less rapidly at the last, so that from the eighth to the tenth day it is entirely abandoned. If patients are too weak and anæmic to take the above treatment at once, it must be preceded by a tonic course. Bromidism, if produced, soon subsides, and leaves no unpleasant after-effects. Of course individual idiosyncrasies should be regarded. He controls insomnia by giving the bromide dose and decreasing morphine dose at night till the latter has been stopped, then he uses fluid extract of coca, with or without capsicum, which controls at the same time characteristic restlessness. Hot baths and cannabis indica are also valuable agents.

For relief of neuralgic pains he places electricity, the local application of ether, and hot water at the head of the list. He gives a mercurial cathartic at the outset of the treatment, and uses afterward mild laxatives. If there is persistent diarrhœa, thirty-minim doses of fluid extract of coca, and sixty-grain doses of subnitrate of bismuth every two or four hours are useful remedies. He makes no restriction in regard to diet, except when stomach and bowels require it. Vomiting, he maintains, is not of so frequent occurrence under this plan of opium withdrawal.

Cocaine, hypodermatically used, after repeated trials, proved much inferior to a reliable fluid extract of coca. The after-treatment exhausts the list of tonics. The writer offers little that is new in this direction.

This work is calculated to inspire the flagging courage of physicians who undertake to overcome the opium habit. The author makes the cure of the "toxic neurosis," as he calls it, appear not very feasible, but not such a difficult task as it is often considered.

A Manual of Human Physiology, including Histology and Microscopical Anatomy, with Special Reference to the Requirements of Practical Medicine. By Dr. L. Landois. Translated from the Fourth German Edition, with Additions, by William Stirling, M.D., Sc.D. With three hundred and eighteen illustrations. Vol. II. Philadelphia: P. Blakiston, Son & Co. 1885.

We have nothing but commendation for the second and last volume of Professor Landois' work, and we can only say again what was stated when reviewing the first volume, that it is the most complete and satisfactory text-book on physiology extant. The translator and publisher have each done something to increase the value of the volumes. Dr. Stirling has added numerous useful annotations, and a large number of new plates from the works of Bramwell, Ross, and others have been inserted. We wish that every medical student and physician could be drilled on these volumes.

Growth of the Hair.—Professor Molleschot, of Turin, has published the results of a long series of investigations, from which he concludes that the hairiness of an individual is in inverse relation to his body weight. The heavier the person the less rapid is the growth of his hair. The latter is greater in summer than in winter, the reverse of what obtains in the lower animals. He also made the astounding discovery that cutting the hair makes it grow more abundantly. It is curious to see how much labor is often expended to but little purpose.

Shakespeare's Physician.—In the churchyard at Fredericksburg, according to the *Allg. Wiener Med. Zeitung*, is a tombstone with the following inscription: "Here lies Edward Heldon, practising physician and surgeon, friend and companion of William Shakespeare, of Avon. He died after a brief illness in the year of Our Lord 1618, æt. 76."

Reports of Societies.

AMERICAN GYNECOLOGICAL SOCIETY.

Tenth Annual Meeting, held in Washington, D. C., September 22, 23, and 24, 1885.

Tuesday, September 22d — First Day — Morning Session.

The Society met in the Columbia University, and was called to order at 10 A.M., by the President, Dr. William T. Howard, of Baltimore.

The following members were present: Drs. W. T. Howard, W. L. Richardson, of Boston; Frank P. Foster, of New York; M. D. Mann, of Buffalo; Joseph Taber Johnson, of Washington; H. P. C. Wilson, of Baltimore; W. T. Lusk, of New York; J. R. Chadwick, of Boston; R. B. Maury, of Memphis; R. S. Sutton, of Pittsburg; W. H. Baker, of Boston; John Byrne, of Brooklyn; B. B. Browne, of Baltimore; J. P. Reynolds, of Boston; T. A. Emmet, of New York; E. W. Jenks, of Detroit; H. J. Garrigues, of New York; S. C. Busey, of Washington; Ellwood Wilson and William Goodell, of Philadelphia; T. A. Reamy, of Cincinnati, and Theophilus Parvin, of Philadelphia.

invited guests.

The following were unanimously elected: The members of the Washington Obstetrical and Gynecological Society, Drs. R. P. Wilson and W. P. Chinn, of Baltimore; E. C. Dudley, of Chicago; F. Howard, S. J. Radcliffe, R. Reyburn, J. F. Dyer, G. C. Ober, of Washington; J. M. Browne, U.S.N.; and Dr. De Roaldes, of New Orleans.

Dr. Samuel C. Busey, of Washington, then delivered

the address of welcome,

in which he extended to the Society the greetings of fellowship of the Washington Obstetrical and Gynecological Society, and its hospitalities of fraternity. Others have come to fill the places of the lamented dead, and the future gives promise of even greater progress and higher excellence in the aims of conscientious and scientific medicine.

The first paper was read by Dr. Busey, and was entitled

the natural hygiene of the child-bearing period.

The hygiene of pregnancy relates to the preservation of the health of women during those periods of her life-history intervening between conception and the commencement of labor. The processes characteristic of that period were those of transformation, development, and growth, and were physiological; nevertheless they were terminated by more or less violence and injury to both mother and child. The unavoidable mortality, however, is small.

The hygiene of the child-bearing life includes that of pregnancy and the puerperium. They are equally important and interesting. But the hygiene of pregnancy has a much broader significance than a classification and detailed description of the disorders of pregnancy and the methods of prevention.

The concurrent succession of natural phenomena and results which with such uniformity subdivide the course of normal child-bearing life into epochs, which distinctly mark the evolution, climax, and decadence of productivity, point with unerring certainty to the operation of general laws for the female economy.

From its beginning to its end pregnancy is characterized by continuous and progressive functional and organic activity, and along its entire course the signals of danger are displayed in quick succession at short intervals.

Puberty, matrimony, pregnancy, parturition, lactation,

the post-pregnant restoration of ovarian activity, and the menopause, constitute epochs in the life-history of child-bearing women. Upon the course, progress, and succession of these events depend health, life, and longevity. Each has its physiological characteristics, and each may be associated with a variety of pathological conditions.

First pregnancies are the most dangerous, and the danger is increased by too early and too late primiparity. The fertility of the female increases from the commencement of the child-bearing period until the climax is reached, and then declines to its extinction. The age of greatest safety of pregnancy coincides with the age of greatest fecundity.

Dr. Busey then referred to the period of lactation as an important epoch in child-bearing life, and afterward directed attention to the cessation of ovarian life, precocious nubility and precocious puberty.

The paper was discussed by Dr. J. R. Chadwick and Dr. J. P. Reynolds, of Boston, and the discussion was closed by Dr. Busey.

Dr. H. J. Garrigues, of New York, then read a paper on

PUERPERAL DIPHTHERIA

based on twenty-six cases treated by him in the New York Maternity Hospital, and one in the New York Infant Asylum, during the years 1882 to 1884. The diphtheritic infiltration was commonly light gray; appeared first as small discrete spots which spread and fused together, forming large thick patches, intimately connected with the subjacent tissue.

Under the name of "dissecting metritis," he had described eight cases in which a large portion of the muscular tissue separated and was finally expelled from the cavity of the uterus.

As regards etiology, everything that protracts labor, or causes wounds of the genitals, the introduction of the hand into the womb, etc., predisposed to the disease. The real cause, however, was infection.

The first symptom was fever; temperature mostly between 103° and 104° F.; generally the patient complained of pain; the lochia were usually scanty, dirty grayish-red, and offensive, but might be normal. The general symptoms generally preceded the local changes by several days.

Concerning diagnosis, the infiltration must be distinguished from the yellow color which abraded surfaces take under the bichloride of mercury bandage.

The prognosis, as to event, was doubtful; five out of his twenty-nine patients having died. Recovery was complete, except in dissecting metritis, where the loss of substance might interfere with future pregnancies, and predispose to rupture of the uterus.

The prophylactic treatment consisted in limiting vaginal examinations as much as possible, thorough antisepsis by means of the bichloride of mercury, etc.

The curative treatment included thorough cauterization of all affected parts within view with a solution of equal parts of chloride of zinc and distilled water; washing out the uterus with a bichloride solution—1 to 4,000—and leaving within the cavity a suppository containing a hundred grains of iodoform. This was repeated once in twenty-four hours, and a vaginal douche, with the same solution, was given every three hours.

The general treatment consisted of the use of ergot, quinine, morphine, alcohol, and digitalis; and the temperature was controlled by the use of cold.

Dr. W. T. Lusk, of New York, spoke of the good results which had followed the use of the antiseptic pad described by Dr. Garrigues, and also related one case which seemed to illustrate the possibility of the disease being communicated by direct contagion.

Dr. H. P. C. Wilson, of Baltimore, had been much interested in the paper, and also the remarks by Dr. Lusk, because he had avoided all bandages or napkins which might possibly obstruct free discharge of the lochia.

Dr. W. L. Richardson, of Boston, agreed entirely with what had been said by Drs. Garrigues and Lusk.

The paper was further discussed by Dr. John Byrne, of Brooklyn, who referred to deformities of the vagina, etc., as the result of this disease; by Dr. Frank P. Foster, of New York, and by Dr. M. D. Mann, of Buffalo.

The Society then adjourned.

TUESDAY—FIRST DAY—AFTERNOON SESSION.

The Society was called to order by The President.

Dr. Joseph Taber Johnson, of Washington, read a paper entitled

FOUR CASES OF OÖPHORECTOMY, WITH REMARKS.

The remarks pertained chiefly to the desirability of early diagnosis and early operation in cases of disease of the ovaries and tubes which might justify the performance of Battey's or Tait's operation for their relief.

The first case was one of chronic ovaritis and menstrual epilepsy in a patient twenty-nine years of age. Both ovaries and tubes were removed, and with improvement in the patient's general condition.

In the second case, Dr. Johnson removed both ovaries and the tubes, and the operation was followed by complete recovery; the patient being well both in mind and body.

The third case occurred in Miss S——, twenty-four years of age, and was one of excessively painful dysmenorrhœa, with all the accompanying grave phenomena. Both ovaries and tubes were removed, followed by an excellent recovery.

Mrs. X——, forty years of age, and the mother of three children, determined to have the operation performed, and finally Dr. Johnson removed both ovaries and tubes; the patient died on the sixth day of exhaustion, and the autopsy gave little evidence of the cause of death.

Dr. Johnson then discussed the question of early diagnosis and early operation in suitable cases. Even under discouraging circumstances the operation was one of the most successful in modern surgery, and he suggested that if our means of diagnosis were so perfect as to give medical as well as moral courage to operate in advance of the growth of adhesions, the percentage of mortality in this country would be much reduced.

The paper was discussed by Dr. Sutton, of Pittsburg, who advocated the operation; by Dr. Baker, of Boston, who thought the operation should remain as one of last resort; by Dr. T. A. Emmet, of New York, who believed that it should never be performed for dysmenorrhœa; by Dr. W. T. Lusk, of New York, who fully agreed with Dr. Baker that, when the exploratory incision was made and the ovaries found healthy or with only a few Graafian follicles scattered over their surface, they should be returned and the abdominal wound closed with the acknowledgment that the source of the clinical phenomena had not been found; by Dr. H. P. C. Wilson, of Baltimore, who thought there was great danger of performing the operation too frequently, although there were many cases in which nothing could be done for the patient except to remove the ovaries and tubes; by Dr. Jenks, of Detroit, who thought the operation was limited to a very few cases: by Dr. Reamy, of Cincinnati, who believed that some conservatism should be taught concerning the operation, and the discussion was continued by Dr. M. D. Mann, of Buffalo, Dr. Emmet, Dr. Sutton, Dr. Jenks, and was closed by Dr. Johnson.

The Society then adjourned to meet on Wednesday at 10 A.M.

(To be continued.)

For the Relief of the Burning Pain in Erysipelas of the Face.—Dr. Häcker recommends painting the painful parts with a solution of cocaine, five grains, in rose-water, one-half ounce.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, September 9, 1885.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

HYDATIFORM MOLE.

DR. H. J. BOLDT presented a specimen removed from the uterus of a woman who, according to the statement of the attending physician, had been flowing for ten or twelve days. When Dr. Boldt saw her she was extremely anæmic, with almost imperceptible pulse, and was losing blood profusely. The vaginal tampon had already been employed, but without effect so far as arrest of the hemorrhage was concerned. The uterus was somewhat enlarged, the vaginal portion softened, patulous, and dilatable, but not dilated. Dr. Boldt introduced a sponge tent, and dilated the cervical canal, after which the interior of the uterus was explored and a hydatiform mole, slightly adherent to the fundus and sides, was removed.

The specimen was not of so much interest as the alarming condition of the patient, which necessitated immediate relief in order to save her life. The case illustrated the fact that sometimes it was essential to adopt relief measures promptly without regard to exactness in diagnosis, and leave the positive diagnosis to be determined after the immediate danger had been passed.

MULTIPLE NECROSIS FOLLOWING VACCINATION.

DR. W. P. WATSON presented a patient with the following history: A girl, now five years and nine months old, weighed nine pounds when born, cut her lower incisors when five months of age, and the anterior fontanelle was closed, probably, at about the age of one year. She did not have either any eruption on the skin, or the snuffles, and remained healthy until two years of age. The mother has always had very good health, has not had a miscarriage, and is the mother of six other healthy children, five living, and one died of small-pox. The father died of acquired phthisis, but his parents and relatives were all healthy. The mother's relatives were all healthy. There was no history of either hereditary or constitutional disease on either side.

When two years old the child was vaccinated by the health-inspector, and the mother says that he made two incisions just below the insertion of the deltoid, which bled so freely as to require a little time and some kind of applications to check the hemorrhage. The mother also says that he used two vaccine points; whether animal or humanized Dr. Watson was unable to ascertain positively, but the probability was that it was animal virus.

On the *third* day after the vaccination, the child was sick in bed with fever, and on the *fifth* day the mother noticed on the outer aspect of the left forearm a swelling which was very much inflamed and elevated. One week later a similar swelling, and in about the same situation, appeared upon the right forearm. Two weeks afterward a like swelling appeared over the left scapula, and two months subsequently one upon the outer aspect of the right leg. At the end of a week or ten days those upon the left forearm and over the scapula opened and discharged profusely pus of green color, and the discharge from the other swellings was of the same character when they were opened. The abscesses continued to discharge unhealthy pus for two years, and during the last year several spiculæ of bone have appeared in the sinuses, and have been removed by the mother. The first spicule came from the left forearm and was removed about eight months ago; the last one was removed from the sinus in the right forearm about two months ago. (The specimens were exhibited.) All the sinuses are now closed entirely. The left elbow is anchylosed at an angle of from 20° to 30°; motion seems to be perfect in the right elbow-joint.

The case illustrated the fact that accidents other than the transmission of syphilis might occur after vaccination, and, furthermore, that such accidents were not the fault of either physician or patient.

One point of interest with reference to the abscesses was that they occurred mostly on the same side with the vaccination. Another point of interest was that the axillary glands on the left side never suppurated, although they were enlarged for more than a year.

The child is now in comparatively good health. Dr. Watson asked for opinions concerning the cause of the abscesses; at the same time expressing his doubt as to whether the vaccination had any direct relation to the accidents.

DR. BOLDT asked if it had been determined positively that the child received no injury at the point of vaccination after the inoculation was performed.

DR. WATSON answered that the mother told him that on the third day the point where the vaccine matter was inserted was very much swollen and inflamed, that the child's skin was dark-colored, but there was no eruption, and he could not ascertain that the part had been injured. He further remarked that it was proper to state that the same health inspector, although not a medical man, had vaccinated hundreds of other subjects; but whether similar accidents had ever followed or not he could not say, but it was probable that there had not, as he had not heard of a similar case.

DR. BOLDT said that in the latter part of last May a child was vaccinated, and on the eighth or ninth day, at the point of insertion, a swelling began to develop which increased in size for two days, when he was asked by the mother to see the patient. He then found that the child was suffering from erysipelas, and at that time all violent contact with the vaccinated part was positively denied. The erysipelas soon subsided under treatment, but a swelling soon showed itself at the ankle-joint which soon suppurated, and a sinus was formed that extended from the internal malleolus nearly to the toes, and sufficiently deep to allow him to touch the metatarsal bones with a sound. A few days afterward another swelling developed at a short distance above, and from this one a very large quantity of pus was evacuated. A short time subsequently a swelling came near the knee-joint and extended from a little below the joint to the lower third of the thigh, and into this one a drainage-tube was placed. Some time afterward another abscess formed in the body of the gastrocnemius muscle, and a large quantity of pus was evacuated from it.

Dr. Boldt learned finally that, on the day previous to that on which any special redness was noticed at the point of vaccination, the mother left the child with one of her good friends, who allowed it to play about the yard, and that it fell and hurt itself upon the leg and rubbed the scab off somewhat, although not entirely.

Of course the neighbors thought that the abscesses were due to the vaccination, but it was much more probable that they were due to the injury and the erysipelas.

DR. HEINEMAN thought that vaccination might develop some latent tendency to bone disease, and that the question of coincidence should always be borne in mind in all such cases.

THE PRESIDENT remarked that, with the frequent occurrence of symmetrical necrosis, it was probably nothing more than a coincidence in Dr. Watson's case. It was a fact that in this country, as well as elsewhere, there existed a growing anti-vaccination party, and that it included many medical men. Not long since he was interviewed on the subject by the President of the Society for the Prevention of Cruelty to Children, Mr. Henry Bergh, who is also President of the Anti-vaccination Society. Dr. Wyeth thought that vaccination should be encour-

aged whenever the opportunity presented itself, and that the medical profession should sustain its scientific claims.

Dr. W. M. Carpenter directed attention to a fact in his experience, namely, that the local disturbance following the use of bovine virus had been much severer than that after the use of humanized virus. This might increase its liability to develop latent disease, to which Dr. Heineman had referred.

Dr. Messenger, whose experience in vaccination had been large, had not met with any serious accidents except when there was a strong predisposition to some constitutional disease, as struma, etc. He believed that vaccination should be encouraged, most assuredly.

Dr. Watson thought the point made concerning the severity of the local effect produced by animal virus was a good one, and was one that his observations sustained. He also thought it well to state to the parents or the patients that the results were likely to be more severe than if humanized virus had been used.

Dr. J. Lewis Smith presented a specimen of acute nephritis associated with diarrhœa in an infant. The specimen was referred to the Committee on Microscopy.

Dr. Boldt asked Dr. Smith if he placed any connection between the diarrhœa and the nephritis.

Dr. Smith said it might be that the diarrhœa was conservative, as it was sometimes in Bright's disease occurring in adults.

Dr. Boldt referred to the case of a child thirteen months old with intestinal catarrh, which he thought was due to improper diet. On the day previous to its death complete suppression of urine occurred, and the temperature rose until just before death it was 108.2° F. The autopsy revealed acute nephritis.

Dr. F. Ferguson presented a specimen of

PERFORATING ULCER OF THE DUODENUM—PERITONITIS,

removed from the body of a man forty-five years of age, a native of Poland, and a tailor by occupation. He was admitted into New York Hospital on September 2, 1885. But very little history could be obtained from the man, on account of his condition as well as his inability to speak English. He had been sick with pain in his stomach and constipation for one month.

On admission he was found emaciated; no thoracic lesions, abdomen tender and retracted. He died two days after admission. While in the hospital he vomited several times. His heart action was regular but very weak. His temperature ranged between 100° and 105° F.; his pulse 72 to 82; his urine was negative.

There was an ulcer in the duodenum, triangular on the mucous surface of the intestine, with sides half an inch in length; and on the peritoneal surface circular and one-eighth of an inch in diameter. There was intense peritonitis, with a great deal of lymph in the peritoneal cavity. The mucous membrane of the stomach was normal, as also were the other organs.

Dr. Ferguson also presented a specimen of

ULCERATIVE ENDOCARDITIS,

taken from the body of a boy thirteen years of age, and born in the United States, who was admitted into New York Hospital August 10, 1885.

He gave no family or previous history bearing on his case. Some three years previous to present illness he was laid up for two months with indefinite pains in his leg, but no swelling. Three months previous to admission he had been laid up for two or three days with vomiting, but suffered no pain. For the last year he has been short of breath. In the latter part of June he complained of pain and heaviness in the left chest, and his shortness of breath was more marked. While his pain diminished in severity, his breathing became more labored, and he steadily grew weaker.

On admission he was well nourished, but anæmic. There was slight general anasarca. The sternum is prominent. The jugular veins are also unusually prominent. The cardiac area is increased. The apex beat cannot be felt, and there is a distinct epigastric beat. Over the præcordia there is a to-and-fro friction murmur, and palpation reveals a friction thrill. There is a loud blowing murmur heard in the seventh space in the nipple line, and from this location the first sound of the heart is transmitted to the left, and is more marked on inspiration. In the second space, just to the right of the sternum, is a double murmur, the systolic transmitted upward. The pulse is regular and of fair force. The inspiration is everywhere jerky, and there are numerous friction sounds. The liver and splenic areas are slightly increased.

During the first part of his residence in the hospital his case responded well to stimulants; the œdema, especially of his face, disappeared, and at the end of ten days he was allowed to dress and sit in his chair. This apparent improvement soon gave place to distressing dyspnœa and pain in his abdomen. Toward the last of August and the first few days of September he gradually failed. His anasarca became more marked; his heart action more rapid, irregular, and feeble; and his urine more scanty in quantity.

He died on September 5th, with respiration at 110; pulse varying from 120 to 140 per minute.

The amount of urine passed each twenty-four hours while in the hospital varied from ten to twenty ounces, with a specific gravity varying from 1.018 to 1.028, and at times a mere trace of albumen, while at other times there was considerable amount. His temperature was nearly normal during his residence in the hospital. His pulse varied from 100 to 140; his respiration from 40 to 110 per minute.

The heart is the organ of chief interest. The organ is larger than normal. Its cavities are dilated and walls hypertrophied. The mitral valve is greater in its capacity than normal, the segments of the valve are thickened. There is a shred of vegetation attached to one of the cusps of the aortic valve three-quarters of an inch in length and as large as a crow-quill. Just below the aortic valve there is an opening in the septum, circular in shape and nearly one-half inch in diameter. This opening is through one of the segments of the tricuspid valve. On the auricular surface of this valve there are many shreds of vegetations. There are low vegetations on the cusps of the pulmonary valve.

While this may be a congenital defect in the septum, it is more likely the result of an ulcerative process which had its origin in the left ventricle and destroyed the septum. The septum once defective the right ventricle of the heart became involved and presented similar vegetations to those found in the left ventricle. The liver presented the lesion commonly known as nutmeg, the other organs the lesions commonly seen in cases of heart-diseases of long standing.

Dr. J. Lewis Smith thought that the condition of the heart presented by Dr. Ferguson was congenital. In perforation of the ventricular septum there is commonly a preternatural narrowing of the pulmonary orifice; but such narrowing was absent in this specimen.

The Society then went into executive session.

The next meeting will be held September 23d.

G. Bunge, in the *Zeit. Physiol. Chem.*, describes experiments on the form in which iron exists in egg-yelk. He is led to believe that food does not contain iron in inorganic combinations, but that it only exists in complex organic compounds which have been formed by the vital processes. It is absorbed and assimilated in this form, and then converted into hæmoglobin. This is, he is aware, apparently at variance with the observations of practical physicians. The apparent contradiction may, he thinks, be explained by the hypothesis that inorganic iron salts prevent the decomposition of the organic iron compounds in the intestinal canal.

THE MISSISSIPPI VALLEY MEDICAL SOCIETY.

Eleventh Annual Meeting, Held at Evansville, Ind., on September 8, 9, and 10, 1885.

(Condensed from a Special Report to THE MEDICAL RECORD.)

THE opening session was consumed in listening to the reports of committees and officers.

THE SECRETARY said that, judging from the letters received by him, there seemed to be a misapprehension on the part of members and others as to the nature and objects of the organization. It was not a legislative body, had no constitution and by-laws, and had nothing whatever to do with questions of ethics. He recommended that a sketch of the Society be prepared, setting forth its aims, and published in one of the medical journals.

The first paper was by DR J. E. LUTCLIFF, of Indianapolis, on

PERINEAL SECTION WITHOUT A GUIDE FOR URETHRAL STRICTURE.

The discussion of the paper was chiefly upon the question of the existence or non-existence of impermeable stricture, the majority of the speakers expressing their belief that impassable strictures were sometimes to be met with.

DR. G. B. WALKER, of Evansville, Ind., presented a communication on "Puerperal Fever and Puerperal Septicæmia." He did not favor antiseptic vaginal injections either before or after labor. The general opinion expressed in the ensuing discussion was that there was no real difference between puerperal and surgical septicæmia, and that strict surgical cleanliness was absolutely necessary. The preference among antiseptics was given to bichloride of mercury.

The next paper (see page 342) read was by DR. E. S. MCKEE, of Cincinnati, upon

INTRACRANIAL CEPHALHÆMATOMA.

DR. LOUIS BAUER, of St. Louis, presented a paper upon

THE COCAINE HABIT.

He related the case of a man who used alcohol to excess, to whom was given hydrochlorate of cocaine hypodermatically for the relief of the inordinate thirst from which he suffered. The patient obtained the drug, and began to use it on himself, commencing with one-fifth of a grain and increasing to ten grains, hypodermatically, and he now has the cocaine habit, but has an aversion to alcohol. The speaker thought that, of the two evils, the cocaine habit was to be preferred.

DR. J. H. LETCHER, of Henderson, Ky., then read an article on

CATGUT LIGATURES,

in which he expressed his preference for this kind of ligature. The majority of those who discussed the question, however, were strongly opposed to catgut.

DR. J. C. PEARSON, of Mitchell, Ind., followed with a communication entitled the "Pathological Changes in Dysentery."

After this the

PRESIDENT'S ADDRESS

was delivered by DR. F. W. BEARD, of Vincennes, Ind. The speaker sketched briefly the history of medicine in Indiana, dwelling especially upon that of Vincennes, an old French post, about which there were many points of interest. He then gave an account of the formation and growth of the Mississippi Valley Medical Society.

Short addresses were also made by Drs. Porter, Letcher, Eastman, and Burton, the speakers insisting upon the necessity of more work being done, and calling upon the members to exert themselves and to prepare interesting and original papers for presentation to the Society.

The scientific labors of the meeting were then resumed by Dr. A. C. BERNAYS, of St. Louis, who read a paper on

CHOLECYSTOTOMY.

The speaker reported a case, exhibiting specimens of the gall-stones removed, and described his method of operating.

DR. L. D. BROSE reported a case of "Fracture of the Skull" in a young child. The patient had now grown up to boyhood, and was presented to the members. A considerable portion of one parietal bone, where the fracture had occurred, was missing. This led to some discussion upon trephining of the skull, and the indications for its performance.

DR. EDWARD BORCK, of St. Louis, then read a paper (see page 344) entitled

REMARKS ON ABDOMINAL SURGERY, WITH CASES.

The general opinion of those who discussed the paper was in favor of an early operation.

DR. WM. BYRD, of Quincy, Ill., presented a communication on "Tetanus," in which he recommended treatment by Fowler's solution in doses of twenty drops every two hours.

Other papers were then read by Dr. G. V. Wallen, of Indianapolis, on "Nasal Stenosis;" by Dr. Wm. Porter, of St. Louis, on "Some Errors in Physical Diagnosis;" by Dr. A. Dixon, of Henderson, Ky., on "Progress in Medicine," and by Dr. A. Sawyer, of Hillsboro, Ill., on "The Relation of Mind to Matter."

The following officers were elected:

President—Dr. A. Dixon, of Henderson, Ky.

First Vice-President—Dr. G. W. Burton, of Mitchell, Ind.

Second Vice-President—Dr. T. D. Washburn, of Hillsboro, Ill.

Third Vice-President—Dr. Wm. Cheatham, of Louisville, Ky.

Secretary—Dr. H. J. B. Wright, of Olney, Ill.

The Society was then adjourned to meet in Quincy, Ill., on the second Tuesday in July, 1886.

THE SURGICAL SOCIETY OF PARIS.

Stated Meeting, June 3, 1885.

M. HORTELOUP, PRESIDENT, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

M. GILLETTE reported a number of cases of

INTESTINAL OBSTRUCTION FROM BILIARY CALCULI.

One case in particular was that of a woman, sixty years of age, having a right femoral hernia, who presented, however, all the symptoms of an internal strangulation of the intestines. After three days, during which an expectant plan of treatment was followed, the patient obtained relief by the expulsion from the rectum of about twenty-five biliary calculi. In referring to a similar case, reported at the preceding meeting of the Society by M. Cruveilhier, the speaker regretted that laparotomy had not been performed, as he thought the patient's life might thereby have been saved.

M. CRUVEILHIER replied that his case was one of

OBSTRUCTION FROM A SINGLE LARGE CALCULUS.

The patient was seen by three hospital surgeons, but none of them was able to make a positive diagnosis. A simple laparotomy would not have sufficed, as the gall-bladder was found, at the autopsy, to contain a large stone, whose presence had excited inflammation and would have soon led to rupture.

M. Farabœuf then read a paper on certain peculiarities in the

ANATOMY OF THE SCAPULO-HUMERAL ARTICULATION,

and the surgical deductions to be drawn therefrom. The speaker referred particularly to the anterior and superior ligaments, and to the mechanism of subtricipital luxations. The anterior ligaments, leaving out of consideration the capsular and the subscapular tendon, were chiefly two, which might be designated, in respect to their points of origin and insertion, as the supraglenoprehumeral and the pregleno-subhumeral. These ligaments may be readily seen when the articulation is opened from behind. Their bony attachments are so strong that, when strained, they may cause a fracture of the neck of the scapula. This fracture may be produced in the cadaver by a violent blow on the shoulder from behind forward, while the humerus is in a position of outward rotation. The reduction of

SUBCORACOID DISLOCATION,

after Kocher's method, is explained by the fact that outward rotation of the arm, after it has been approximated to the chest, causes a relaxation of the posterior ligaments which have been put upon the stretch by the anterior displacement of the head of the humerus. In

SUBTRICIPITAL LUXATION

the head of the bone escapes under the circumflex nerve and passes beneath the tricipital tendon.

M. Verneuil related a case of

ENCHONDROMA OF THE UPPER JAW.

The specimen was interesting from the fact that the tumor enclosed a small central sequestrum.

M. Polaillon then presented a report upon a communication of M. Féré, of Meaux, entitled

THE NATURE AND ETIOLOGY OF URETHRAL FEVER.

The author believed that the febrile attacks following operations upon the urinary organs were, in the majority of instances at least, merely relapses of intermittent fever excited by traumatism. He cited several cases in which operations of circumcision, internal urethrotomy, and even simple catheterization, practised upon individuals who had previously had malarial fever, were followed by chills recurring sometimes for several days at regular intervals. These attacks were controlled by quinine. Another patient, in poor general condition, but free from any malarial poisoning, had no chill or elevation of temperature after internal urethrotomy. The reporter agreed fully with the writer of the paper as regards the nature of so-called urinary fever.

M. Marc Sée maintained that urethral fever was a distinct affection, and that she cases cited by M. Féré were exceptional.

M. Verneuil had several times remarked upon the difficulty of diagnosis between a relapse of intermittent fever and true urinary fever. In the latter case, however, the urine frequently contained pus; there was pain over the kidneys, and there was less regularity in the intermissions than in malarial fever. It was not a matter of supreme importance, however, to make a diagnosis in every case, since both conditions were readily controlled by quinine.

M. Féré presented another communication upon the

SUBSTITUTION OF FUNCTION OF THE MEDIAN NERVE BY THE ULNAR.

The case was one of injury to the elbow, leading to destruction of a portion of the median nerve. Sensation and motion were in time restored to the parts supplied by this nerve. But while electrization of the median nerve caused no contraction, that of the ulnar was followed by movements of the muscles normally supplied by the median.

M. Berthand exhibited a patient upon whom M. Le Dentu had performed

NEPHRECTOMY

two months previously. The operation was for the removal of a large calculus. The wound had closed firmly, without any fistula.

M. Lagrange reported a case of

THYROIDECTOMY.

The patient was a woman, twenty-two years of age. The operation was performed after Julliard's method. In order to prevent the retention of the discharge in the retrosternal pouch, the operator secured the aponeurotic attachment of the tumor to the lower part of the incision in such a way as to facilitate the flowing away of the fluid. The patient had entirely recovered at the end of three weeks.

The Society then adjourned.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE NEW PHARMACOPŒIA—ITS MERITS AND DEMERITS—AND THE CHANGES THEREIN—PREPARATIONS MADE TO CORRESPOND WITH THOSE IN THE UNITED STATES PHARMACOPŒIA.

London, September 4, 1885.

The new edition of the British Pharmacopœia has appeared within the last few days. The alterations and additions are, as expected, very numerous. The omissions are less noteworthy and are only twenty-two in number. Among the articles omitted are iodide of cadmium, iodide of iron (*not* its syrup, which still remains), enema tabace (though tobacco itself remains), magnetic oxide of iron and the moist peroxide, green iodide of mercury, liquor atropiæ (liq. atrop. sulph. remains and is consequently to be henceforth used always instead of the other), and acetate of soda. The list of omissions might have been extended with advantage. The medical student of the future will think so at any rate, seeing how numerous the additions are. Arnica, chirata, cusparia, elemi, galbanum, hemidesmus, laricis cortex, lobelia, mezereon, mori succus, pyrethrum, sambuci flores, and many others of little therapeutic value and infrequent employment, retain their place. Extract and tincture of conium remain, though most physicians now use the succus.

The additions are too numerous to enumerate. They number one hundred and fourteen. Amongst them are of course boric, chromic, hydrobromic, and salicylic acids; coca, its hydrochlorate, and lamellæ of the same; several new salts of soda, or sodium, as we are now to term them; ergotine; jaborandi and its alkaloid; a liquor ferri acetatis (two strengths of this) and a liquor ferri dialysatus, the latter being considerably stripped of its glory, as we are informed that "this solution of dialysed iron, so called, is a solution of highly basic ferric oxychloride or chloroxide of iron, from which most of the acidulous matter has been removed by dialysis." Menthol, thymol, eucalyptus, iodoform, nitro-glycerine (in the form of chocolate tablets termed *tabellæ*), oleates, sulphocarbolate of sodium, salicine, gelsemium, apomorphine, and lodeina are all in their respective places, and there are useful preparations of many of them. We also welcome chrysarobinum (Goa powder), oleic acid, cascara sagrada, paraffinum, durum et molle, caffeina, aloin, morphinæ sulphas, and liquor sodii ethylatis. Most of us, I think, will feel very doubtful as to the advantage of adding meconic acid, iodide of arsenic, frangula bark, calx sulphurata (sulphide of calcium), and some others. As to the last named preparation I fancy few therapeutists outside the school of Ringer have much faith in its value to check suppuration.

We look in vain for picrotoxine, bisulphate of quinine (soluble sulphate), sodium nitrite, kaolin (as an excipient), pancreatin, or any new salts of lithium. It is some consolation to find the physical characters of lithium citrate now correctly given for the first time. It is no longer erroneously described as amorphous and deliquescent. For this and other pharmaceutical emendations we have doubtless to thank the distinguished pharmacists who have taken part in the preparation of this edition. More careful directions are given for making many of the preparations, and the strength of many of the Galenical ones is regulated by passing the solid ingredients through sieves having meshes of specified degrees of fineness varying in different cases.

The nomenclature has in many instances undergone revision. Thus, we no longer read sodæ carbonas, but sodii carbonas, and so throughout. The affix of the alkaloids is now made *-ina* uniformly, *e.g.*, quinina. This may be all right, but vapor coninæ reads rather oddly. arnicæ radix is now arnicæ rhizoma; similarly with several others, rhizome has replaced radix. Physostigmatis semea is a doubtful improvement on physostigmatis faba. Why not semina? We find colchica semina. Spelling has not escaped the attention of the editors. Assafœtida drops one s, and ecbalium doubles its l.

The strength of many preparations has been altered—mostly in the direction of increase. Among those which have their strength increased are liquor iodi, liquor arsenicalis, tincturæ quininæ, and injectio morphinæ hypodermica. The first three of these are increased in strength about eleven per cent.—the dose remaining unaltered. The morphina solution is increased *twenty per cent.;* the minimum dose remains one minim, the maximum being placed at five instead of six minims. Oleum phosphoratum is increased in strength *thirty-three per cent.*, the maximum dose being unaltered, while the minimum dose advances from three to five minims. The alterations in the last two preparations are likely to lead to inconvenience, and, in that of the morphina solution, also danger. It is to be regretted that the strength of aqua lauro-cerasi and infusum digitalis, respectively, should not have been reduced so as to make the doses the same as those of the other waters and infusions. Their dosage remains exceptional, as before. So does the strength and dosage of the following tinctures: Tr. cantharidis, tr. capsici, tr. cannabis indica. The maximum dose which may be given of tr. camph. co. is still placed at a drachm, which is also the maximum limit assigned to vinum antimoniale, though when used as an emetic, the latter may be given in larger doses. Under vinum ipecacuanhæ the ordinary and the emetic doses are both stated. I am sorry to see the same is done under sulphate of copper, an emetic which is discountenanced by most toxicologists on account of its poisonous properties if it is retained and emesis not produced. Lastly, it is what a schoolboy would call "a burning shame" that the dose of tinctura aconiti should continue to be officially stated as "five to fifteen minims." Every third-year's student knows better than this—nay, most first-year's men do.

Some of the alterations I have mentioned, although likely to be inconvenient for a time, have, however, one great claim to favorable notice, viz., that thereby some of the preparations are made to correspond in strength with similar ones in the United States Pharmacopœia. It is to be regretted that more has not been done in this direction, especially as the projected International Pharmacopœia is still in the clouds. The United States Pharmacopœia is, too, one which should have especial claims upon British physicians, being that of a nation speaking the same language and having many laws and customs in common—a nation, in fact, belonging to the same Anglo-Saxon race equally with ourselves.

The new terminology of the alkaloids corresponds with that in the United States Pharmacopœia. So does the designation of soda-salts, as sodii sulphas, etc. The latter alteration also has chemical usage to commend it to us. Tinctura quininæ now corresponds exactly with that of the United States Pharmacopœia both in strength and composition, being now made with the hydrochlorate of quinine instead of with the sulphate. Oleum phosphoratum is now made of the same strength as the United States preparation, and liquor arsenicalis is made to approximate very closely in composition to its American representative. Liquor iodi now contains the same amount of iodine—five per cent.—as the United States solution, but a different proportion of iodide of potassium. I may remark, in passing, that several of the preparations now contain so much "per cent." of the chief ingredients instead of, as before, an odd amount. One preparation (pulvis glycyrrhizæ compositus) is now made to conform in composition to that of its fellow in the Prussian Pharmacopœia.

OUR PARIS LETTER.

(From our Special Correspondent.)

THE CHOLERA QUESTION—TRANSPLANTATION OF EYE—DEATH OF DR. LUNIER.

PARIS, September 11, 1885.

As cholera is naturally occupying the attention of the public, both in and out of the profession, I shall lay before your readers a discussion that took place at the annual meeting of the Association Française for the Advancement of Sciences, at which Dr. Bouchard questioned the correctness of the principles emitted by Professor Koch respecting the etiology of the disease. The following is a summary of Dr. Bouchard's communication: 1. According to Professor Koch cholera is an infectious malady of which the comma-bacillus is the pathogenic agent. 2. The intestinal cavity is the exclusive habitat of this bacillus. 3. This bacillus does not penetrate into the blood nor into the lymph, and as it does not enter the tissues, it cannot produce the general accidents of cholera by means of intoxication; the presumption therefore is that it secretes in the intestinal cavity a virulent substance which, absorbed at the surface of the intestine, determines the poisoning of the entire organism. Dr. Bouchard gives the results of his experiments which he had performed with iodoform, naphthaline, to destroy the comma bacillus of cholera and the micro-organisms of typhoid fever, of which the following are the conclusions: 1. Analogy leads one to think that cholera is an infectious malady, resulting from a microbe. 2. The pathogenic microbe, whatever it may be, produces or incites the human organism to produce a morbid poison ("poison-cholérique"). 3. To this special intoxication is soon added another intoxication by a normal poison ("poison-urénique"). 4. The pathogenic agent of cholera cannot occupy exclusively the intestinal cavity. 6. The comma-bacillus is not the productive agent of the choleraic poison.

In looking over these conclusions it will be admitted that neither one nor the other of these distinguished physicians has thrown much light on the etiology or nature of the disease, except that they both agree that it is due to a microbe; but, what the microbe is or what part it plays in the pathology of cholera, is as obscure as ever.

In my letter, which was published in THE RECORD of July 4th, I gave an account of the transplantation of the eye of a rabbit to replace the eye of a young girl, which had been removed to prevent sympathetic inflammation of the other. Dr. Chibret, of Clermont-Ferrand, who operated, promised further details of the case to the Paris Academy of Medicine, but I have not seen that he has done so. I find, however, some interesting observations on the case in the *Revue Générale d' Ophthalmologie*, in which the writer questioned the propriety of the operation, remarking that to transplant an organ is not an

operation impossible, but to make the transplanted organ live; that is, to place it in a condition that it may contract vascular and nervous connections with the cruentous tissues to which it was adapted, is quite another question, that is, whether the transplanted organ will ever be in a condition to perform the physiological functions required of it. As far as the eye is concerned, Dr. Chibret has precisely resolved the question in the negative. The writer further states that on the fifteenth day of Dr. Chibret's operation, the cornea was completely destroyed.

This result, however, does not discourage the operator, who attributed this destruction to the pressure of the thread used for the sutures and to the thinness of the cornea of the rabbit's eye, and Dr. Chibret is hopeful that he will yet succeed, not only in getting the transplanted eye to live in its new position, but to re-establish the function of vision in this transplanted eye. Dr. Fano, commenting on this subject in his *Journal d'Oculistique*, makes the following sensible remarks: "We shall remind those who may be tempted to perform this operation, that the introduction into the eye of an organic mass destined to undergo mortification in a very short time, will expose the patient to the risks of putrid infection."

Dr. Lunier, the well known Alienist, died on the 5th inst., from an attack of pneumonia which he contracted a few days before, while out shooting. Dr. Lunier was sixty-three years of age. He took his degree in 1849, and after having been physician to lunatic asylums in the Provinces, he was appointed, in 1864, Inspector-General of the Lunatic Asylums and Prisons throughout the country. He was a member of the Academy of Medicine, and officer of the Legion of Honor. He edited the "Annales Medico-Psychologiques," and was the author of several works on mental pathology, among the most important of which may be cited: "Studies on Mental Maladies," "On the Progressive Increase in the Number of Lunatics," "The Part Played by Alcoholic Drinks in the Increase in the Number of Cases of Insanity and Suicide."

He was the founder of the French Temperance Society, in which cause he took a very active part. I may here mention that the members of the French Temperance Society are not pledged as they are in England and America. Dr. Lunier did not approve of the oath, as he considered that if a person required such a measure to keep him from drinking, his self-restraint could not be worth much. He never approved of teetotalism, as he thought that from the exhaustion caused by the exigencies of a civilized life, some stimulant would be more or less daily required, whether in the form of wine or anything else. At the temperance meetings he always endeavored to impress on his hearers that it was not the moderate use of wine that should be contemned, but its abuse. Dr. Lunier's death, in this cause at least, will be a great loss, and he will be universally regretted in and out of the profession.

The remains of Dr. Thuillier, member of the French Cholera commission to Egypt, where he fell a victim to the disease in 1883, have been brought to France at the expense of the State, and on arriving at Marseilles they were immediately conveyed to Amiens for interment. On the day of the funeral the public monument raised to the memory of the lamented deceased, will be officially inaugurated.

MALARIAL ALBUMINURIA.

To the Editor of The Medical Record.

Sir: By the very title of my paper on "Some of the more Uncommon Symptoms and Complications of Malaria," printed in The Medical Record of September 12th, Dr. Nelson will see that I do not wish to put forward as novel what is simply unusual, but have endeavored to add my share to interesting clinical material.

Dr. Thompson's paper on "Temporary Albuminuria caused by Malaria," which, I am very sorry to say, escaped my notice, does not cover the ground as to renal disease in malaria, for temporary albuminuria is not equivalent to nephritis.

With reference to the cases of bronchial trouble, which I designated "Apneumatosis" in malarial subjects, my explanation is based on mechanical principles, readily understood, and perhaps more satisfactory than Dr. Nelson's internal determination.

Respectfully yours,

L. Weber, M.D.

25 West Forty-Sixth Street.

"A MEDICAL VIEW OF ARMY MORALS."

To the Editor of The Medical Record.

Sir: If not taking up too much space in your columns, I should like to add something to my article of July 11th on the above subject.

I was stimulated to write the article named, not alone by the extract from *Col. Med. Journ.*, but also from the fact that carelessness among army surgeons, either in field or hospital, gave to not a few soldiers of the Rebellion a "syphilitic record," when they were entitled to no such honor. While the medical department was composed largely of men of ability, many regiments enlisted in 1863–64 were provided with very inferior men as surgeons. Especially is this true of Western regiments. To the incompetency of the latter are due many of the mistakes in diagnosis. Place a soldier in the hospital with any form of eruption of the skin, and he was in danger of acquiring a syphilitic record. Even "itch" has been so characterized; gonorrhœa and syphilis were notoriously confounded.

There are soldiers debarred from pensions by this same "hospital record," in whom we can find no evidence of "constitutional syphilis," and whose history points out the fact that gonorrhœa was the disease, if a venereal disease occurred. "Private A—— contracts gonorrhœa at L., August, 1862. Is in hospital for treatment. Has iritis in March, 1865. Discharged, April, 1865. Vision destroyed, August, 1866. Applies for pension, and is debarred by record, the inference being 'syphilitic iritis.'" "Give a dog a bad name," etc.

Medicus says it were "better to divest such questions of sentiment." So do I, but sometimes sentiment and fact are hard to separate. The error begun in the army is still continued. Physicians make certificates of treatment for syphilis, who, if upon the witness-stand, could produce very little evidence of having treated anything of the kind.

The word "specific" is used, as the word malaria or the one-time "sick liver," simply as a cloak to cover our ignorance. In the case above, an iritis following after an attack of syphilis is presumptively "specific." But it requires something more than sharpened teeth in children to show that the parents ate grapes; and other evidence than iritis is necessary to show its syphilitic origin. Neither should we jump at another conclusion and say "gonorrhœal ophthalmia."

In my article referred to, reference was had simply to "soldiers of the rebellion," not to soldiers of other countries, nor to soldiers of America other than the ones specified. The chances for syphilitic infection among our soldiers "on the plains," taken in connection with the comparatively few now in the army, should not be taken as evidence in the question at all, the opportunities for the gratification of the sexual appetite being much greater in the latter than in the former.

Medicus includes my "five presumptive cases" with the one positive case. That would be called presumption in a mild degree, on his part. In none of the five cases mentioned was the evidence stronger than in "Private A——," and in three of the cases the evidence was altogether subjective.

Taking the statistics as given by Medicus, "twelve soldiers per thousand," who will say that any physician

is warranted in applying the word "specific" to *all* scrofulous children "whose fathers had been in the army?" Apply it in the same ratio to the children of the clergy!

As to the moral responsibility, there is no difference in the fact that one soldier had gonorrhœa and another syphilis. But it is a very important point to decide, when confronted with diseases of the lungs, throat, skin, eyes, and spinal cord, etc., in soldiers who have obtained a "syphilitic record." G. T. M.

THE DUTY OF THE CONSULTING TO THE ATTENDING PHYSICIAN.

To the Editor of The Medical Record.

Sir: A recent experience impresses me with the necessity of opening a discussion that may lead to the correction of an evil connected with consultations, fortunately not very frequent, yet common enough to demand attention.

A case happening some time ago, and the recent one alluded to above as occurring lately, will illustrate one point of the subject.

In the first case I am free to say there was a careless blunder on my part. It was a patient on whom the chills of laryngeal phthisis were mistaken for those of malarial fever. The throat symptoms led to my requesting the services of another physician to make a laryngoscopic examination. The result was the discovery of the tell-tale ulceration. I did now what I should have done before—went over my case carefully and found plain enough evidence of the disease. The consulting physician, who, with my consent, was to attend to the treatment of the throat, evidently took no especial pains to excuse my error of diagnosis. At any rate he was retained, and I left.

The recent affair is quite different, for no fault can be found with me in this case.

A primipara, after a long first stage of labor, had fairly entered on the second stage. About twenty-four hours had elapsed from the start, and during the last twelve hours the excitement of the friends, with which we are all so familiar in cases of tedious labor, had reached such a height that my efforts to suppress it were unavailing, and I was requested to call some one in consultation, notwithstanding my assurance that it was unnecessary. Previously I had made arrangements with a nearby physician to hold himself in readiness to assist me when required; had provided myself with chloroform, and made complete arrangements to apply the forceps if they were indicated.

Still, it was insisted upon that some prominent obstetrician should be summoned. My evil genius, I suppose, brought the name of one who enjoys a good reputation, and a messenger dispatched to him soon procured his attendance. I explained to him that the case was one of ordinary tedious labor, and that I had asked him in only to allay the apprehensions of the family as to the safety of the patient. As the pains, in the meanwhile, had become weaker, and I had myself concluded it would be permissible to apply the forceps, the doctor's offer to use the instruments was accepted by me and the woman was delivered, but with a perineal tear nearly to the sphincter. I had met with a similar misfortune myself in several cases lately, and for this reason had delayed instrumental interference as long as possible.

Although my services were continued until convalescence of the patient, when my bill was sent in I was informed that I "had allowed Mrs. —— to suffer for three days, when the case was put in another physician's hands, who saved the life of the mother and child."

I afterward learned that the consulting physician, when spoken to by the family in reference to my supposed mismanagement, made a show of defending me, but it seems that he "damned me with faint praise" so effectually that I found myself dismissed, and him in my place prescribing for the patient.

In the phthisis case there is but little doubt that the influence of the doctor exerted in my favor would have retained me in the family.

The questions are: Was it his duty to have used his influence in this way? Should he have retained the case, coming into his possession in the way it did?

As regards the other case, no one will deny that I was treated—to use the mildest term—unfairly. If the *truth* had been properly stated to the family by the doctor, it would have prevented all the unpleasant after-consequences.

These cases are samples of what every physician in general practice occasionally meets. One doctor in this city, often called in consultation, has a habit of remarking to the friends, that "if he had been called before there might be a chance," and this habit, I know, very seriously curtails his consultation practice.

What remedy have we? I suggest that we pass around the names of such offenders. If they do not care for honor, perhaps they may for money. Justice.

New Instruments.

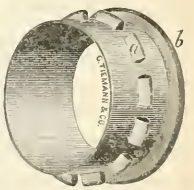
A NEW DEPARTURE IN CIRCUMCISION.

By J. W. ROSS, M.D.,

Surgeon U. S. Navy.

Circumcision, as I have seen it and taken part in it during the past sixteen years, whether performed with or without clamps, etc., has seemed to me altogether too formidable for an operation of its size, requiring a general anæsthetic, tedious, slippery, bloody, inexact, inelegant. Wishing to do away with some, at least, of these opprobria and relegate circumcision to the insignificance it deserves, thereby leading to its much more frequent performance, I have devised the little instrument figured below.

It is a light, flat ring of hard rubber, with two ridges upon its outer surface, the posterior one, *b*, continuous, the anterior one, *a*, interrupted or notched. It is to encircle the penis in the *cul-de-sac* under the prepuce, the latter being drawn forward over the instrument and compressed against it, in the groove between the two ridges, by a small cord wound round its integumentary surface. The foreskin is then to be severed just in front of the anterior or notched ridge by a circular sweep of the knife, the angle formed by the ridge and the horizontal surface serving as a director. The notches in the anterior ridge are to facilitate introduction of the sutures.



The instrument has recently been used upon a patient of Dr. Sidney A. Fox, Surgeon of the Brooklyn Elevated Railway, and proved highly satisfactory to both patient and surgeon. From this operation and some experiments, the following details and suggestions are thought valuable:

Anæsthetize the parts as thoroughly as possible with cocaine solution, push the ring over the glans and place it so that the posterior ridge, *b*, be well behind the corona glandis, and the anterior ridge, *a*, almost directly over it. It is advisable that the ring be of such a size as to require some little force in order to pull the glans into it. There is no danger of strangulation as the instrument is too broad to slip entirely behind the glans. The cut represents the exact size of the one used, which will answer for almost any adult penis, the prepuce being generally very dilatable and the glans compressible. When phimosis exists, the edge of the prepuce may be nicked at non-vascular points sufficiently to allow the subsequent steps of the operation. It is better not to use any lubricant, as it is unnecessary and makes the organ and in-

strument difficult to manage. Get all the tissue you wish to remove in front of the anterior ridge and then winding a small, soft, strong, inelastic cord pretty tightly twice around the foreskin directly upon the groove between the two ridges, tie its ends upon the dorsum with a double surgeon's knot. A piece of loosely-twisted, ordinary white cotton wrapping-twine, about the size of a D violin string, was used by us and found to answer perfectly.

It proved unnecessary to draw the cord as tightly as had been intended. There being no tension upon the prepuce, it has no disposition to retract, and the cord need only be tight enough to prevent hemorrhage. Should it be too tight, it might lead to subsequent sloughing. Should it be desired to make the operation absolutely painless, local anæsthesia of the skin at the proposed line of incision may be produced with ether or rhigalene spray. Circular excision of the prepuce immediately anterior to the notched ridge should be made with a very sharp knife or razor, dividing skin and mucous membrane down to the hard rubber at one sweep. While this is being done the operator should hold the penis in his left hand, the posterior portion of the instrument between the left thumb and forefinger, while the patient, or some other assistant, makes slight traction upon the free edge of the prepuce. The tough movable tissues are disposed to roll away from the knife.

Apply cocaine freely to the cut edges and introduce plenty of fine sutures with a small curved needle entered at the bottom of the notch upon the mucous surface and brought out on the surface of the skin. The introduction of each suture was considerably expedited by picking up the edge of the mucous membrane with a slender pair of toothed forceps. After the sutures are all tied, the constricting cord may be tentatively relaxed, to be retightened upon appearance of any hemorrhage. In the case operated upon, although the prepuce was abnormally vascular, and the instrument removed very soon after tying the sutures, the hemorrhage was practically nil then and afterward. This was due to the compression, the astringency of the cocaine, non-separation of the cut mucous and integumentary edges, number of sutures, non-division of the frænum and its artery, and the fact that all the vessels were cut at an equal distance from the free edge of the foreskin. It is obvious that, with the instrument under consideration, it would be impossible to divide the frænum, as this is pushed out of the way of the knife entirely.

If, at the proper stage of the operation, it be deemed advisable to tie or twist any of the divided vessels, the instrument would greatly facilitate doing so by the support and control it furnishes. The instrument was not removed from its original position until the completion of the operation. Should there be danger of hemorrhage, it might be left *in situ* almost indefinitely after the cord is removed. I would advise against much haste in removing the sutures. They had better be left in for three or four days lest separation take place during the troublesome erections, which occur so commonly after circumcision. After the operation a cold one per cent. solution of carbolic acid was kept applied to the penis on lint.

A few weeks after the operation, except for a delicate red streak at the line of incision, the penis looked as though it had never sported a prepuce, as though the circumcision had been congenital. There were no angles, tags, flaps, or lumps (as are almost invariably found after circumcisions where the prepuce has been dragged forward and divided in front of the glans), because the skin and mucous membrane, while in their natural relative position, had been divided evenly and circularly along the line of the corona glandis, and had never been allowed to separate. Leaving the operator out of the question, such a consummation is very gratifying to the patient. The average man is not quite, but almost as solicitous about the appearance of his penis as about that of his nose.

Professor Otis saw our patient a month after the operation, and made a very complimentary memorandum of the appearance of the penis as well as a sketch of the circumcision ring.

Two of these instruments, one for adults, the other for children, would probably be all that the general surgeon would require. For exceptional cases special-sized ones could be procured, as Messrs. Tiemann & Co. propose to make them quite inexpensive.

Dr. Fox's record of the case referred to above.—"May 22, 1885, circumcised a patient with redundant prepuce, using instrument devised by Surgeon J. W. Ross, U. S. Navy.

"No general anæsthetic was used, but a four-per cent. solution of cocaine hydrochlorate was applied to the prepuce and glans. There was slight pain upon dividing the skin, but none in the mucous membrane, or during the introduction of the sutures. The patient sat up in a chair throughout the operation, and rendered valuable assistance. There was virtually no hemorrhage, only a few drops of blood escaping upon loosening the compressing cord. No ligature, torsion, or styptic, was used or required during or after the operation. The sutures were removed in exactly forty-eight hours after the operation, the patient having been scarcely confined to his bed, and union was perfect, having taken place by first intention. After experience and observation in this operation while House Surgeon in Charity Hospital, New York, and in private practice since, I would point out the following advantages of Ross' operation over all others with which I am acquainted: Its ease, neatness, bloodlessness, requiring no general anæsthetic, ligature, or styptic; no necessity for any assistant except the patient; speedy union, and perfect result.

"SIDNEY A. FOX, M.D.

MURRAY, J. M., Passed Assistant Surgeon. Resignation accepted, to take effect January 1, 1886.

ROSS, J. W., Surgeon. To special duty at New York.

ERUPTION FROM ANTIPYRINE.—Dr. J. Henry Fruitnight, of this city, writes: "In the report of the proceedings of the Practitioners' Society of New York, which appeared in the issue of THE MEDICAL RECORD dated September 5, 1885, Dr. A. A. Smith is stated to have asked the members present whether they had observed cutaneous eruptions after the administration of antipyrine. Dr. Ball responded in the affirmative. It is my desire to add my testimony corroborating the observations of Dr. Smith. It is my impression that I was among the very first in this city to make use of this drug. The results of my observations upon the action of the remedy were communicated by me to the members of the Northwestern Medical and Surgical Society of this city at the meeting held October 15, 1884. I quote from that Society's book of records as follows: 'Antipyrine was administered to two patients afflicted with acute phthisis. In one case a fine papular, itchy eruption showed itself, similar to that which sometimes appears in persons taking quinine, and which disappeared when the medicine was discontinued. In both cases perspiration was very profuse, just as Dr. Smith had observed in his cases.'"

ADDRESS TO THE NEW YORK ACADEMY OF MEDICINE.[1]

BY A. JACOBI, M.D.,

PRESIDENT OF THE ACADEMY.

FELLOWS OF THE NEW YORK ACADEMY OF MEDICINE: It is a source of intense gratification to me to greet you this evening in the beginning of a new season of co-operative work, after a long vacation. May the labor of the coming months be successful, both for ourselves and for the medical world. *Ars longa, vita brevis.* Art is so extensive, indeed, and life so short, that we have to concentrate all our efforts to accomplish a certain amount of result.

In behalf of our common interests I crave your attention, first, for a few facts which I consider of great importance in regard to medical progress. They are connected with the session of the International Congress held in Copenhagen, from August 10 to 16, 1884. In a general meeting held on August 14th, upon propositions made by Sir James Paget, of London, Professor Ewald, of Berlin, Professor Bouchard, of Paris, and Dr. Billings, of Washington, the following resolution was passed: That an International Committee be formed for the Collective Investigation of Disease, in connection with the work of the International Congress, and that a certain number of gentlemen do represent their respective countries thereon. The gentlemen designated for that purpose were Trier and C. Lange, of Copenhagen; E. Bull, of Christiania; Rauchfuss, of St. Petersburg; Ewald and Bernhardt, of Berlin; Schnitzler, of Vienna; Pribram, of Prague; Koranyi, of Buda-Pesth; D'Espine, of Geneva; Bouchard, of Paris; Lepine, of Lyon, Sir William Gull and Mahomed, of London; Humphry, of Cambridge; Sir Joseph Fayrer, for British India; Gutierrez-Ponce, for South America; N. S. Davis, of Chicago; A. Jacobi, of New York; and Isambard Owen, Secretary-General, of London. The only changes which have since taken place in the list of membership have been brought about by the untimely death of Dr. Mahomed, and the addition of Axel Key, of Stockholm, and Runeberg, of Dorpat.

According to a circular distributed by the Secretary-General some time ago, the main objects which the Committee seeks to attain through the Collective Investigation of Disease are to widen the basis of medical science, to gather and store the mass of information that at present goes to waste, to verify or correct existing opinions, to discover laws where now only irregularity is perceived, to amplify our knowledge of rare affections, and to ascertain such points as the geographical distribution of diseases and their modifications in different districts. It will be its endeavor to place clearly before the whole profession the limits and defects of existing knowledge, as well as to stimulate observation, and to give it a definite direction. It will be a not unimportant incidental result of its work should it tend, as is hoped, to the better training of the members of the profession in habits of scientific and practical observation, and in systematic methods of recording the facts which they observe.

The age in which we live has seen enormous advances in the sciences on which the fabric of medicine rests, such as chemistry and other branches of physics, physiology, and pathology. Each of these has taken giant strides. It must be admitted, however, that purely medical knowledge has scarcely made proportionate progress. It cannot be expected that it should do so, as it deals with the aberrations of the most complex of organisms, is of all sciences the most difficult, and demands the greatest patience and the largest accumulation of data.

Hitherto the advancement of medical science has been brought about mainly by individual effort. The value of such work in the past we in no way underrate, nor do we desire to lessen the amount of it in the future; but in medical science there is much that defies interpretation from individual experience, and many problems so far-reaching in an ever-widening field, with elements so manifold, that no single man, however gifted and long-lived, can hope to bring the whole within his range. The need, therefore, in medicine, of that combination and concentration of individual work which is adopted in many other branches of science and in commerce, and to which increasing facilities of inter-communication have given so much impulse and so much strength, cannot be questioned. Indeed, it may be said that, resting on individual research alone, medical knowledge can be advanced but slowly and with difficulty. Future progress to any great extent must be the work, not of units acting disconnectedly, but of the collected force of many acting as one. For many to act as one, organization is needed; that organization it is the purpose of our committee to supply.

Disease is many-sided; and we wish to include in our organization those who see it from every side. All, therefore, whether hospital physicians, family and school attendants, specialists, medical officers of the Army and Navy, and of workhouses and asylums, will be asked to contribute their quota of observations to the common fund."

These are both the motives and the propositions of the committee appointed at Copenhagen. In regard to them, and collective investigation in general, the favorable opinion of the profession has been expressed frequently. But now and then a voice is still heard disparaging its utility, and discouraging the collection of facts on a large scale for the reason that the procedure has not yet been demonstrated to be useful. Indeed it has not, for it has never been tried to a large extent. We shall hardly insist, however, that the ground stone must not be laid, because the tower is not yet on the edifice; that the seed must not be sown, because the fruit cannot be harvested to-day, or was not gathered yesterday.

Hesitation has also been expressed from another point of view: one of our foremost medical journals (the *Boston Medical and Surgical Journal*, of September 4, 1884) makes the remark that those who labor only for personal renown will not enter enthusiastically into the work proposed by the committee. But its demands are very trifling indeed, the questions to be settled by the observations of large numbers are but few, and of such a nature as not to expropriate those who are able and anxious to arrive at, and be credited with, scientific results of their own and benefit by the reputation attached to them.

If the remark above-quoted were founded on reality, whoever worked for personal reputation only, would not even participate in the discussion of a scientific society for fear that his remarks, coupled with the essay of somebody else, would miss the opportunity of being listened

[1] Delivered Thursday, October 1, 1885.

to as the main topic of an evening's conversation. Now, on the contrary, we are in the daily habit of seeing experience published, and ingenuity displayed in just such discussions. Nor do I believe that as another journal has it (the *New York Medical Journal*, September 4, 1884), that "the answers coming from a great body of men of diverse views would constitute but a catalogue of raw impressions," and that "when the facts to be observed are of a nature to call for exquisite discrimination on the part of the observers, to multiply the number of the observers, is to depreciate the general quality of the work." For the more uncertain the correctness of observations is apt to be, the more numerous they ought to become. Single observations have settled a fact but very rarely. The very existence of large societies proves the instinctive demand for variety and comparative appreciation of observations. Is not every physiological fact known to us as the outgrowth of a number of experiments of many men? And pathological knowledge the result of a great many autopsies by different men in many countries? What is individual experience but the accumulation of a multitude of facts of a similar nature by one man? What is science but the result of accumulated experience, collected and compared of many men, countries, and ages? Are a hundred meteorological stations more efficient, or less so, than none would be? I do not belong to that class who believe a problem easy of solution merely because its solution is anxiously sought for, nor do I deny difficulties because they are obstacles to the accomplishment of cherished ends, but I know that we are in a better position to serve the co-operative work of all countries now that steam and telegraph have reduced distances, mail and travel have multiplied intercourse, and we are to-day as near St. Petersburg as our ancestors were, a hundred years ago, to Lake Erie or the James River.

Thus it appears evident that the difficulties are not excessive. As to the usefulness of collective investigation the opinions will become all but unanimous. The efforts of the British Medical Association, and the Medical Society of Berlin, and the fair success of an attempt at solving a problem connected with the etiology of croupous pneumonia, made in the Medical Society of the County of New York, during the last year, are sufficiently promising for the collective investigations of the future. In their interest it is that I propose to make a further communication, and request your co-operation.

The Central Committee on Collective Investigation of the International Congress has selected the following subjects, viz.: Rickets, Chorea, Acute Rheumatism, and Cancer, planned a number of simple questions in regard to them, mainly to their etiology, and expects as simple answers. Being the Secretary of the American Sub-committee, I have gathered all of them in pamphlet form, added a few introductory general remarks, supplied by the Central Committee, and present herewith a specimen for your inspection. Those of you—I hope all of you—and those of the profession at large who will learn of this request, are respectfully asked to interest themselves and their friends in behalf of the undertaking, notify me of their desire to be furnished with a copy, and comply with the suggestions of the Committee contained therein. We do not look for immediate achievements. For the complex of sciences and arts called medicine has required thousands of years to arrive at its present condition; the aggregation of many wills and forces has resulted in a slow evolution only. No single discovery even, nor the first attempts at collective investigation, will effect a revolution in medicine. But what we do hope to accomplish is the gathering of facts on the strength of an improved method, the confirmation of old, and the acquisition of new knowledge, and thus to contribute to the success of at least this one Committee. It need not matter how much may have, nay, has been done, to mar the success of the next International Assembly, and to deprive us of the opportunity long looked forward to of greeting the giants of science, the celebrated teachers, the ingenious experimenters, and our literary or personal friends of Europe, on our own soil. For an International Congress will never convene under the roof of a house divided in itself, though the division may be the work of a few sacrilegious hands only.

But this is a sad theme, known to everybody here, deplored by everybody who feels as both a personal grief and a public calamity the humiliation which is involved in the hesitation on the part of the Congress to assemble in our country.

It is in profound sorrow that I pass by the subject; I prefer to speak of another topic, which, while it is not directly connected with any of the aims and immediate purposes of this Academy, concerns us as professional men of the State of New York and the Union. I allude to the almost unexpected success on the part of the profession of the State of New York in harmonizing a large majority of the medical men of the United States.

Let me explain. Chapter II., Art. IV., Sec. 1, of the Code of Ethics of the American Medical Association, reads as follows: "A regular medical education furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations, the good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner, who has a license to practise from some medical board of known and acknowledged responsibility recognized by their association, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship, or his aid refused in consultations when it is requested by the patient. But no one can be considered as a regular practitioner, or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry."

This paragraph has so often been criticised by both friends and adversaries that it is unnecessary to refer again to its contradictions, its "nevertheless" and "but," and to its implied acknowledgment of modern "homœopathy." For let us not forget that the Code of Ethics of the American Medical Association saw the light forty years ago, and that what they call "homœopathy" now-a-days differs from Hahnemannism of those times in everything but the name. They now claim that their practice is not based on an exclusive dogma; they claim to teach, in their schools, and do teach, anatomy, physiology, pathology, and organic chemistry, and thus come up to the requirements of the above article of the Code of Ethics of the American Medical Association. Indeed, if there were no better grounds for their rejection they would to-day be entitled to membership in the Association.

What the Medical Society of the State of New York, in its sessions of 1882 and 1883, adopted in its stead ("Trans. of the Med. Soc. of the State of New York for the Year 1882," p. 75), in a code of medical ethics which covers two pages instead of the eighteen pages of the Code of Medical Ethics of the American Medical Association ("Proceedings of the National Medical Conventions, held in New York, May, 1846, and in Philadelphia, May, 1847," pp. 91–106. Philadelphia, 1846), reads as follows:

"Members of the Medical Society of the State of New York, and of the Medical Societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine. Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the demands of humanity."

Compare with these brief sentences the explanatory declaration of the American Medical Association, passed

unanimously in its session at New Orleans, of April, 1885. There and then it was

"*Resolved*, That clause first of Art. IV., in the National Code of Medical Ethics, is not to be interpreted as excluding from professional fellowship, on the ground of differences in doctrine or belief, those who, in other respects, are entitled to be members of the regular medical profession. Neither is there any other article or clause of the said Code of Ethics that interferes with the exercise of the most perfect liberty of individual opinion and practice.

Resolved, That it constitutes a voluntary disconnection or withdrawal from the medical profession proper, to assume a name indicating to the public a sectarian or exclusive system of practice, or to belong to an association or party antagonistic to the general medical profession.
